Preparation.—Take of Resin in fine powder six troyounces; Lead Plaster thirty-six troyounces. To the lead plaster, melted over a gentle fire, add the resin, and mix them. *U. S.*

Take of Resin four ounces; Lead Plaster two pounds; Hard Soap two ounces. To the lead plaster, previously melted with a gentle heat, add the resin and soap, first liquefied, and stir them until they are thoroughly mixed. *Br.*

This is the plaster which, spread upon muslin, forms the sparadrap commonly known as *adhesive plaster* or *sticking plaster.* A. W. Gerrard (1874) suggests that for use in summer one-fourth the quantities of soap and resin ordered in the second formula should be used; in the spring, one-half the quantity will answer; but in cold weather, the officinal proportions are preferable. The German Pharmacopœia prepares for this purpose a plaster from crude oleic acid by heating, by means of a steam bath, 18 parts of the acid with 10 parts of finely powdered litharge, and after the plaster has been formed, which is accomplished without difficulty, adding to the mass 3 parts of resin and 1 part of suet.

Good adhesive plaster should not be sticky at the ordinary temperature; when spread upon muslin, it should be pliable without cracking, and when applied to the skin, should adhere firmly.

Off. Prep.—Empl. aconiti, Empl. arnicæ, *U. S.;* Empl. belladonnæ, *U. S., Br.;* Empl. calefaciens, Empl. opii, Empl. plumbi iodidi, *Br.*

Medical Uses.—Adhesive plaster is chiefly employed for the support of mobile parts, for exerting pressure, for securing the coaptation of *wounds* and *fractures*, for maintaining *surgical dressings*, etc. It is apt to irritate delicate skins.

EMPLASTRUM SAPONIS, *U. S., Br.*—SOAP PLASTER.

Emplastrum saponatum, P. G.; *Emplastrum cum sapone*, F. P.—*Emplâtre de savon*, Fr.; *Seifenpflaster*, G.

Preparation.—Take of Soap sliced four troyounces; Lead Plaster thirty-six troyounces; Water a sufficient quantity. Rub the soap with water until brought to a semi-fluid state; then mix it with the lead plaster, previously melted, and boil to the proper consistence. *U. S.*

Take of Hard Soap six ounces; Lead Plaster two and a quarter pounds; Resin one ounce. To the lead plaster, melted by a gentle heat, add the soap and the resin, first liquefied; then, constantly stirring, evaporate to a proper consistence. *Br.*

The presence of one-seventh of soap in the second formula renders the plaster less adhesive than that of the first formula, in which the soap has been reduced to one-tenth of the whole. The soap plaster of the German Pharmacopœia contains one-fifteenth of soap, and in addition 1.1 per cent. of camphor; and that of the French Codex rather less than one-seventeenth of soap.

Off. Prep.—Ceratum saponis, *U. S.;* Empl. calefaciens, Empl. plumbi iodidi, *Br.*

Among the unofficinal plasters, more or less employed in different sections, the following deserve to be mentioned in this place:—

EMPLASTRUM CERUSSÆ, s. *Empl. album coctum.*—Litharge 10 parts, and olive oil 25 parts, are boiled together with water until the former is dissolved; carbonate of lead, 18 parts, is then added, and the boiling continued until a plaster is formed (*P. G.*). A similar composition containing a little wax and powdered orris root is known as *Mahy's plaster.*

EMPLASTRUM FUSCUM, s. *Empl. matris fuscum, Empl. nigrum s. noricum s. minii adustum s. universale.*—Finely powdered red oxide of lead 2 parts, and olive oil 2 parts, are boiled with constant stirring, until the mass assumes a dark brown color, when 1 part of yellow wax is added (*P. G.*). For some purposes, 1 per cent of camphor is added. The plaster is put up in square cakes and in boxes, and is also sold in the United States as a secret preparation under different names. It is extensively employed by the German population, and known to them as *Mutterpflaster, Universalpflaster,* etc.

LOGAN'S PLASTER.—Boil together over a slow fire olive oil 2½ pints, fresh butter 4 ounces, Castile soap 12 ounces, litharge 16 ounces avoirdupois, until the mass has a pale brown color; then add carbonate of lead 16 ounces, and continue the heat until the plaster is formed; lastly, add 2 drachms of powdered mastich.

Medical Uses.—Soap plaster is generally used to prevent *abrasions, bed-sores,* etc., and, like other plasters containing lead, it possesses some discutient powers. Owing to the thickness of the layer, as it is usually spread, it is apt to be moved from its original position, and is therefore not so efficient as adhesive plaster in preventing bed-sores.

ENEMATA.—CLYSTERS.

Clysmata, Clysteria.—Lavements, Clystères, Fr.; *Klystiere,* G.

Clysters are liquid medicines which are injected into the rectum by means of a syringe, and ordinarily consist of water or of infusions mixed with solutions of salts or holding insoluble substances in suspension. They are rarely if ever prepared by the apothecary, but are generally made at the bedside, and the introduction of formulas into the Pharmacopœia serves mainly the purpose of informing the physician of the mode of their preparation.

ENEMA ALOES, *Br.*—ENEMA OF ALOES.

Lavement aloëtique, Fr.; *Aloeklystier,* G.

Preparation.—Take of Aloes forty grains; Carbonate of Potash fifteen grains; Mucilage of Starch ten fluidounces. Mix, and rub together. *Br.*

Medical Action and Uses.—It is far from certain that the enema of aloes exerts any special influence, or any that would not be secured equally well by a solution of common salt or of a magnesium salt. Aloetic enemata, when they are intended to purge, should be large; but when they are to be retained, to destroy *ascarides* of the rectum, or to stimulate the *uterus,* they should not exceed two or three fluidounces.

ENEMA ASSAFŒTIDÆ, *Br.*—ENEMA OF ASAFŒTIDA.

Enema fœtidum s. antihystericum, Clysma tonicum.—Lavement d'ase fetide, Fr.; *Asafötida-Klystier,* G.

Preparation.—Take of Asafœtida thirty grains; Distilled Water four fluidounces. Rub the asafœtida in a mortar with the water added gradually, so as to form an emulsion. *Br.*

This is identical with a mixture of equal parts of water and milk of asafœtida.

Medical Action and Uses.—The use of asafœtida by enema is often the most eligible mode of its administration, on account of the patient's inability to swallow, as in *hysteria*, or because it acts very promptly, as in cases of *intestinal flatus*. The association of aloes with the emulsion of asafœtida forms a very useful enema in cases of *constipation* with flatulence. A mixture of the wine or tincture of aloes, and tincture of asafœtida, sufficiently diluted with water, is far better than the officinal enema made with water alone.

ENEMA MAGNESIÆ SULPHATIS, *Br.*—ENEMA OF SULPHATE OF MAGNESIA.

Enema catharticum.—*Lavement de sulfate de magnésie*, Fr.; *Bittersalz-Klystier*, G.

Preparation.—Take of Sulphate of Magnesia one ounce; Olive Oil one fluidounce; Mucilage of Starch fifteen fluidounces. Dissolve the sulphate of magnesia in the mucilage of starch, add the oil, and mix. *Br.*

Medical Action and Uses.—The oil and mucilage in this enema are worse than useless. A simple solution of Epsom or of Glauber salts is preferable. It may be used as an evacuant of a constipated bowel when a prompt operation is desired, as in cases of obstinate *constipation* or of *congestion of the brain*. For such purposes an enema should always be large.

ENEMA OPII, *Br.*—ENEMA OF OPIUM.

Enema anodynum s. sedativum.—*Lavement opiacé anodin*, Fr.; *Opium-Klystier*, G.

Preparation.—Take of Tincture of Opium half a fluidrachm; Mucilage of Starch two fluidounces. Mix. *Br.*

Medical Action and Uses.—The quantity of laudanum or of other liquid opiate in an enema must vary with the age and state of the patient, whether a local or a general narcotic effect is sought, etc. As the enema ought to be retained, the quantity of liquid in it should not exceed two ounces; and it should consist of water, which is promptly absorbed, and not of starch, which may not be absorbed at all.

ENEMA TABACI, *Br.*—ENEMA OF TOBACCO.

Lavement de tabac, Fr.; *Tabak-Klystier*, G.

Preparation.—Take of Leaf Tobacco twenty grains; Boiling Water eight fluidounces. Infuse in a covered vessel for half an hour, and strain. *Br.*

Medical Action and Uses.—The infusion of tobacco (U. S. P.) is stronger than this preparation by one-half, but is prepared in the same way, and used for the same internal purposes—that is to say, for producing nausea and muscular relaxation in cases of strangulated *hernia*, and promoting alvine evacuations in *ileus*, as well as in the various cases indicated in the article on Tobacco. Its use requires caution.

ENEMA TEREBINTHINÆ, *Br.*—ENEMA OF TURPENTINE.

Lavement térébinthiné, Fr.; *Terpentinöl-Klystier*, G.

Preparation.—Take of Oil of Turpentine one fluidounce; Mucilage of Starch fifteen fluidounces. Mix. *Br.*

Medical Action and Uses.—In the case of this enema, the proportion of the active ingredient should vary with the case in which it is used, and numerous other circumstances. It is most frequently employed to lessen *tympanitic* distension of the bowels, but is of little use, comparatively, unless the flatus is confined in the colon. It sometimes affords great relief to the suffering from *vesical calculus*. It has been used with alleged advantage in certain cases of *amenorrhœa;* and to destroy *ascarides* of the rectum. It is sometimes administered during a paroxysm of *hysteria*. When it is intended that a turpentine enema shall be retained, its bulk should be small, and it should also be made into an emulsion with yelk of egg.

EPIGÆA.—TRAILING ARBUTUS.

Ground-laurel, Gravel-plant, May-flower, E.

Epigæa repens, *Lin.* *Nat. Ord.*—Ericaceæ, Ericineæ.

Description.—The trailing arbutus is a prostrate hairy North American shrub, about a foot long, growing in sandy woods and flowering in early spring. The thin woody stem is covered with a brown bark. The evergreen leaves are alternate, about two inches long, petiolate, coriaceous, and reticulated; their shape is ovate, the margin entire, the base heart-shaped, and the apex tipped with a short point. The flowers are in small axillary clusters, rose-colored or whitish, fragrant, have a deeply five-parted bracted calyx, a salver-form corolla with the tube hairy inside, ten stamens, and produce five-lobed and five-celled capsules containing numerous seeds. The leaves are inodorous, and have a bitterish and astringent taste.

Constituents.—The leaves contain tannin, which produces a black precipitate with iron salts. Using gelatin as a precipitant, H. K. Bowman (1869) determined its amount to be 3.5 per cent. Jefferson Oxley (1872) proved the constituents to be identical with those of uva ursi, namely, *arbutin*, *urson*, and *ericolin*. Formic acid was also found, and a principle having in the behavior to tests some resemblance to gallic acid, without, however, yielding pyrogallic acid.

Medical Action and Uses.—Trailing arbutus has been compared with uva ursi and buchu; it possesses some astringency, like the former. It has been used for the relief of *strangury* and of *vesical catarrh*. A decoction is prepared with an ounce of the dried leaves and stems in a pint of water, and given in the *dose* of a wineglassful three or four times a day.

EPILOBIUM.—WILLOW-HERB.

Herbe de St. Antoine, Fr.; *Weidenröschen, Antonskraut*, G.

Epilobium angustifolium, *Lin.*, s. E. spicatum, *Lam.*
Nat. Ord.—Onagraceæ.

Origin.—A perennial herb, about four to six feet high, and growing in mountainous woodlands, occasionally also in dry and sunny localities. It is indigenous to North America, Northern Asia, and the greater portion of Europe, and flowers in July and August.

Description.—The root is long, fleshy, yellowish-white, and has a thick bark. The stem is erect, smooth, often reddish, branching above. The leaves are scattered, subsessile, from three to six inches long, lanceolate or linear-lanceolate, nearly entire, with a marginal vein, smooth, pale-green beneath. The flowers are in a long terminal spicate raceme; the calyx adheres to the long linear, four-sided ovary; the four unguiculate petals are spreading, purple-colored, or pinkish and showy. The eight stamens and the style with the long four-lobed stigma are bent downwards. All parts of the plant have a mucilaginous and astringent taste.

Constituents.—Analyzed by C. J. Biddle (1877) the usual constituents of plants were found. The astringent taste is due to a tannin which produces bluish-black precipitates with ferric salts. Gallic acid is also stated to be present.

Medical Action and Uses.—The demulcent, tonic, and astringent qualities of willow-herb are reported to render it useful in mild or subacute forms of *diarrhœa*. It may be given in decoction, and also applied externally to unhealthy ulcers, including aphthæ.

The root and young shoots are eaten by the inhabitants of subarctic regions, and in Russia and Siberia the leaves are used in the place of tea.

EPIPHEGUS.—BEECHDROP.

Cancer-root, E.; *Orobanche de Virginie*, Fr.; *Krebswurz*, G.

Epiphegus (Orobanche, *Lin.*) virginiana, *Bart.*, s. E. americanus, *Nutt.*
Nat. Ord.—Orobanchaceæ.

Origin.—A perennial parasite growing upon the roots of beech trees in North America. It is collected in autumn.

Description.—The subterraneous portion consists of a subglobular scaly tuber, half an inch and more in diameter. The stem is twelve to eighteen inches high, much branched, angular, with ovate scales at the base of the branches and flowers. The flowers are in long spicate racemes, the lower ones fertile and with a short corolla, the upper ones sterile with a long tubular and two-lipped corolla, about one-third of an inch long. The stamens are didynamous, and the superior capsule is one-celled, two-valved, and contains numerous minute seeds. All parts of the plant have a pale-purplish or yellowish-brown color, and a disagreeable, bitter, and somewhat astringent taste.

The constituents of the plant have not been investigated.

Allied Plants, belonging to the same natural order, have been medicinally employed in Europe and America. They are all parasitic, destitute of green foliage, and have a more or less bitter astringent and nauseous taste. We mention the following North American species:—

CONOPHOLIS (OROBANCHE, *Lin.*) AMERICANA, *Wallroth;* Cancer-root, Squaw-root, *E.* It is from four to seven inches high, nearly an inch thick, fleshy, yellowish or brownish, covered with pale shining imbricated scales, resembling a pine-cone. The flowers have a curved two-lipped corolla and four exserted stamens. It grows in oak-woods.

APHYLLON UNIFLORUM, *Tor. and Gr.*, s. Orobanche uniflora, *Lin.* Naked broom-rape, *E.* It grows in woodlands, has a very short, nearly subterraneous scaly stem, bearing one or several peduncles about four inches long, each with a nodding flower, having a curved tubular somewhat two-lipped corolla and included stamens. Its color is whitish or pale tawny.

Medical Action and Uses.—This plant appears to be astringent. Dried and powdered it has been given internally to control *diarrhœa*, and applied externally to fungous and unhealthy *ulcers*.

EQUISETUM.—HORSETAIL.

Prêle, Fr.; *Schachtelhalm*, G.

Equisetum arvense, *Lin.*, and Eq. hyemale, *Lin.* *Nat. Ord.*—Equisetaceæ.

Description.—Both plants are leafless, and grow in damp soil in Europe and North America.

E. ARVENSE, *common horsetail*, has a simple, smooth, fertile stem, appearing in March or April. The barren stems, which alone are used, are slender, about 2 feet long, green, jointed, about 12-furrowed, with simple or compound quadrangular branches, bearing at the joints 4 scales.

E. HYEMALE, *scouring rush* or *shave-grass*, has a simple stem about 2 feet long, round, grooved, the ridges rough, and at the joints with sheaths of about 20 narrow teeth, having a black girdle at the base and tip.

Constituents.—The scouring rush was analyzed by Diebold (1828), who found in it resin, wax, sugar, and other common vegetable principles. John obtained 13 per cent. of ash, 63 per cent. of which, or 8 per cent. of the plant, was silica. The common horsetail gave to Willing (1856) 4.07 per cent. of ash, 41.4 per cent. of which was silica.

Medical Action and Uses.—An infusion of the whole plant is reputed to be diuretic, like its European congeners, which, even from ancient times, have been recognized as possessing this virtue. If too freely used it is said to render the urine bloody.

ERGOTA, *U. S.*, *Br.*—ERGOT.

Secale cornutum, P. G.; *Secale clavatum*, *Mater secalis*, *Clavus secalinus.*—*Spurred rye*, E.; *Ergot*, *Seigle ergoté* (*noir*), *Blé cornu*, Fr.; *Mutterkorn*, *Kornmutter*, *Zapfenkorn*, G.

The sclerotium (compact mycelium or spawn) of Claviceps purpurea, *Tulasne*, replacing the grain (produced within the paleæ, *Br.*) of the common rye, Secale cereale, *Lin.* Steph. and Church, Med. Bot., plate 113.

Nat. Ord.—Fungi.

Origin.—The ergot fungus, *Claviceps purpurea*, Tul., and similar, but propably distinct organisms, are met with upon many grasses. For medicinal purposes that of rye alone is collected. In its development three distinct stages are observed. At the flowering season one or more ovaries in an ear of rye appear covered by a sweet yellowish mucus, the so-called *honey-dew of rye*, which has a disagreeable odor, and is avoided by bees, but attracts other insects, mainly ants and beetles, which were formerly considered to cause the disease of the grain. This honey-dew contains innumerable microscopic cells called *conidia*, and a sugar which reduces alkaline solutions of cupric oxide to cuprous oxide, and is a product of decomposition of the constituents of the ovary, caused by the developing *mycelium* of the fungus. This is formed by filamentous cells called *hyphæ*, with an outer layer, forming a kind of membrane, the *hymenium*, composed of short linear cells, the *basidia*, by which the oblong or oval conidia are separated. In this stage of development it was formerly considered a distinct fungus, and received various names, the best known being *Sphacelia segetum*, Léveillé, which is often used as a descriptive term for the first stage, which is completed when the hyphæ have penetrated the lower part of the ovary and the separation of the conidia ceases.

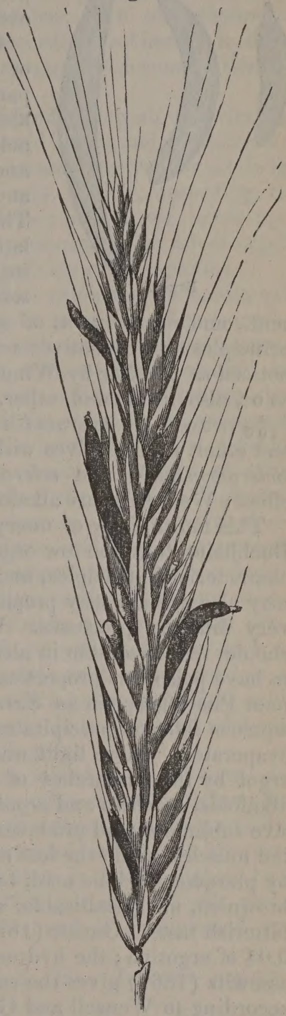
The hyphæ of the sphacelia now begin to unite at the base of the ovary into a compact body, which is purplish-black externally, and rapidly grows in length, carrying upon its apex in the form of a hood the remains of the ovary and fragments of the sphacelia tissue. Occasionally the formation of the honey-dew does not commence until some time after fructification has taken place and the fruit is partially developed; in such a case the ergot will be crowned by a stunted grain. When full grown the second stage of the fungus has been reached, which forms the officinal ergot, and was formerly regarded as a distinct fungus, named by De Candolle *Sclerotium clavus*.

After some months of rest, in the succeeding spring, small circular patches of the external layer are loosened and fold back, while, at the same time, small heads make their appearance, which, at first white, change to yellowish, reddish, and finally purple, and are upon slender, pale-purplish, curved stypes. On the surface of the head, small wart-like excrescences are formed containing the apertures of bottle-shaped cavities or conceptacles, the *perithecia*. Each one of these conceptacles contains a large number of somewhat fusiform cells or spore sacs, the *asci*, each one containing 8 filiform spores, which are discharged from the aperture of the conceptacle, agglutinated in a bundle. The formation of the spores takes place about the time of the flowering of rye, and when brought in contact with its flowers, the spores develop again the sphacelia. The spore-producing heads are nourished from the contents of tissue of the sclerotium, which at first becomes loose and spongy from the disappearance of the oil, and finally shrivels and is destroyed. This third and final stage was formerly likewise regarded as a distinct fungus, known, among other names, as *Cordiceps purpurea*, Fries, until Tulasne (1853) proved it to be merely the final stage in the development of a fungus, as described above. The production of spores may be observed by leaving the ergot in the open air, or by keeping it upon moist earth under a bell-glass; we have noticed it in a damp stoppered bottle containing some ergot.

It will be seen that the officinal ergot is merely the intermediate or dormant state of a fungus, named by the different Pharmacopœias sclerotium, *U. S.*, compact mycelium or spawn, *Br.*, and stromata sterilia (sterile beds), *P. G.*

The United States imported 75,550 lbs. of ergot during the fiscal year 1876–1877; ten years previously but 10 per cent of this quantity.

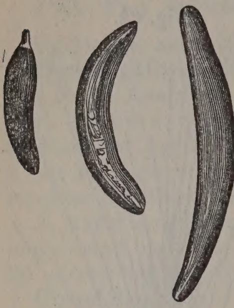
Fig. 62.



Ergotized Rye.

Description.—Ergot forms a solid, somewhat fusiform body, which is 1 to 1½ inch long, subcylindrical, or often obtusely triangular, tapering at both ends, usually somewhat curved, with three longitudinal furrows, and an easily detached, yellowish, small appendage or hood at the apex. It is externally of a purplish-black color, the surface frequently fissured transversely, internally whitish, with some purplish striæ, of a uniform texture, breaking readily with a smooth fracture. It has a peculiar heavy odor, particularly when moist, and an oily unpleasant taste. It is frequently attacked by a mite, from which it may be preserved by thoroughly drying it and keeping it in well-stopped bottles, or by putting a few drops of chloroform into the bottle containing it. When powdered it spoils after a short time, the deterioration being induced by the fixed oil becoming rancid; it should, therefore, not be kept on hand in the powdered state, except for a brief period. It appears to preserve its virtues not much over a year, and should, therefore, be annually renewed.

Fig. 63.



Ergot.

Constituents.—The separation of the constituents of ergot offers peculiar difficulties, which have been in part explained by the recent researches of Buchheim and of Dragendorff (1876); the former regards the active principle as a body somewhat resembling gelatin, and that it is formed from the gluten of the rye ovary, and readily changed by the influence of chemical agents. The latter, in connection with Podwissotzky, has isolated a number of uncrystallizable compounds, possessing more or less activity, the most important being *sclerotic acid*, present to the amount of 4 or $4\frac{1}{2}$ per cent., and *scleromucin*, of which 2 to 3 per cent. are obtained. The following principles are less active: *sclererythrin*, the red coloring matter, which was first noticed as peculiar by Winckler, is soluble in alkalies with a splendid murexid color, also in alcohol, ether, and chloroform; it is present in minute quantity ($\frac{1}{100}$ per cent.); *scleroiodin* ($\frac{1}{10}$ per cent. of ergot) is insoluble in water, alcohol, and ether, and dissolves with a violet color in potassa or strong sulphuric acid. *Sclerocrystallin* and *scleroxanthin* are crystallizable, but without medicinal effect; Wenzell's pure alkaloids (see below) are likewise regarded as nearly inert.

This multiplicity of uncrystallizable principles seems to support the views of Buchheim that the low organization of ergot prevents the formation of well-characterized principles, and that those which are formed are easily altered; it may also explain why preparations possessing some activity may be obtained by very different processes. Wiggers' *ergotin*, obtained in 1830, resembles cinchonic red, is soluble in alcohol, but insoluble in water and ether, and is said to have poisonous properties. Bonjean's *ergotin*, which is officinial in the German Pharmacopœia as *Extractum secalis cornuti*, is merely the concentrated aqueous infusion precipitated by half its weight of alcohol, and the clear filtrate evaporated. More light was apparently thrown upon the active principles of ergot by the researches of Wenzell (1864), who proved the presence of two alkaloids, *ecbolina* and *ergotina;* the former of which is precipitated by corrosive sublimate, and produces decided effects upon the brain, and contractions of the muscles, while the less active *ergotina* reduces the pulse, and is precipitated by phosphomolybdic acid, but not by corrosive sublimate. Both alkaloids are brownish, uncrystallizable, soluble in water, and have an alkaline reaction and bitterish taste. Ganser (1870) obtained from ergot 0.16 per cent. of ecbolina and 0.04 of ergotina; the hydrochlorate of the latter crystallizing in needles. Manassewitz (1867) gives the composition of ergotina as $C_{50}H_{52}N_2O_3$. The alkaloids, according to Wenzell and Ganser, exist in combination with *ergotic acid*, which is volatile, and yields crystallizable salts. Dragendorff (1876), however, regards the two alkaloids as identical, and this seems to have been proven by Blumberg (1878), who found that concentrated solution of ergotina is precipitated by corrosive sublimate, in the same way as ecbolina, and that this precipitate with the latter alkaloid is not insoluble in water. Moreover, Dragendorff denies that ecbolina, which is entirely free from the compounds mentioned above, possesses any decided physiological action. Another alkaloid, *ergotinina*, was isolated by Tanret (1875) from the fixed oil of ergot prepared with ether, by agitating it with acidulated water. Ergotinina is crystalline, but soon becomes resinous; oil of vitriol colors it violet blue; in its effects upon frogs it resembles *picrosclerotina* (producing decreased sensibility, paralysis of the extremities, and death without convulsions). This amorphous alkaloid, which is perhaps impure ergotinina, was obtained, together with *fuscosclerotic acid*, by Dragendorff and Podwissotzky in purifying sclererythrin. That water distilled from ergot, particularly in presence of an alkali, possesses an alkaline reaction, was observed by F. L. Winckler (1826); the alkaline principle was subsequently (1853) named *secalina;* but was found to be identical with *trimethylamin* (*methylamin*, according to Ludwig and Stahl). According to Ganser it does not pre-exist in ergot, but appears to be formed through the decomposition of the protein compounds.

Ergot contains between 28 and 35 per cent. of bland yellowish non-drying *fixed oil*, from which warm alcohol removes some acrid *resin* and *cholesterin;* the latter was obtained by L. Stahl (1865), and its character proven by Ludwig (1869). Schoonbroodt (1866) found in it *lactic acid*, which, according to Buchheim, often renders ergotin strongly acid. *Formic* and *acetic acids* appear also to be sometimes present. Starch is entirely absent. The ash of ergot amounts to 3 or 4 per cent., and consists almost exclusively of phosphates.

Sclerotic acid and *scleromucin* having attracted some attention as medicinal preparations, we give the process by which they may be isolated: Digest ergot, previously exhausted by ether and absolute alcohol, with water, dialyze, evaporate the dialyzate to a syrupy consistence, and treat with sufficient alcohol to obtain a mixture containing 40 to 45 per cent. alcohol, which precipitates the potassium phosphate; while more alcohol, added until the strength is increased to 75 or 80 per cent., precipitates the salts of sclerotic acid, which are soluble in dilute, but insoluble in stronger alcohol, and leave about 19 per cent. of ash. The acid is obtained in a nearly pure state by kneading the mixed sclerotates with 80 per cent. alcohol, and afterwards dissolving them in 40 per cent. alcohol; the solution is mixed with an excess of hydrochloric acid, and after several hours filtered and precipitated with absolute alcohol, whereby the ash is reduced to about 3 per cent., and consists mainly of some silica, manganium, and phosphates of iron and potassium. The acid is not a glucoside, and yields no precipitates with the reagents for alkaloids, except with phosphomolybdic acid a yellow, and with tannin a nearly colorless one. Sclerotic acid is obtained as a yellowish-brown, tasteless and inodorous substance, which has a very slight acid reaction, and is hygroscopic without being deliquescent. It is very well adapted for subcutaneous appliances, in doses of 0.03 to 0.045 gram.

The dark liquid remaining on the dialyzer, when mixed with sufficient alcohol to bring it to 45 or 60 per cent., precipitates the *scleromucin*, which while moist forms a mucilaginous solution with water, but after drying is only partially soluble, differing in this respect from sclerotic acid, which is soluble, in all proportions, before and after drying. Scleromucin is darker in color, slightly hygroscopic, gummy, inodorous and tasteless; yields 26.8 per cent. of ash, and, like sclerotic acid, contains nitrogen, is not a glucoside, and is precipitated by tannin and phosphomolybdic acid.

Off. Prep.—Extr. ergotæ fluidum (liquidum), *U. S.*, *Br.;* Infusum ergotæ, Tinct. ergotæ, *Br.;* Vinum ergotæ, *U. S.*

Physiological Action. *On Animals.*—Among the most characteristic effects of ergot given to dogs in large doses, are dilated pupils, tremulousness, staggering, paraplegia, general prostration, tonic and clonic convulsions, and death. When its action is protracted, the chief phenomena observed are these: gradual paralysis of the hinder legs, thirst, anorexia, emaciation, imperfect sight and hearing, shedding of the hair, debility and slowness of the heart, and death by exhaustion. Mixed largely with the food of pigs, it occasions redness of the eyes and ears, then coldness and gangrene of the latter and also of the tail and limbs. Death occurs usually in convulsions. The action upon birds is even more characteristic; they grow dull and languid; the comb and wattles turn cold, bluish, or ecchymotic, and are ulcerated; black blood flows from the nostrils; the plumage is shed; the pulse and respiration grow slower; and convulsions precede death. Upon pregnant animals (mammifera) the effect of ergot is, among other things, to produce abortion at an advanced period of gestation. Epidemics of abortion in cows have been traced to this cause; and veterinary surgeons employ ergot habitually to expedite languid labor. The internal lesions of animals destroyed by ergot consist of congestion and softening of the lining membrane of the digestive organs; more or less wasting of the muscles in chronic and their rigidity after acute poisoning; the latter being especially marked in the hinder limbs; the bloodvessels of the brain are apt to be congested, and in some cases, it is said, the spinal marrow is softened; the lungs are congested, and the blood is liquid and very dark.

On Man.—In doses of a drachm or two the first action of ergot is to occasion more or less vomiting and purging, but its more characteristic effects are headache, fulness of the head, vertigo, drowsiness, and dilatation of the pupils. The pulse falls from 70 to 60, or even less, in a minute, and this reduction may continue for several days, as may also the dilatation of the pupils. The respiration also becomes slower. The oil extracted from ergot, by macerating it with ether, displays even greater energy in producing the same symptoms, and, in addition, great languor and lassitude, lividity of the skin, painful rigidity of the muscles, and sometimes diuresis. These effects may continue for several days. The oil exhibits no influence upon the gravid uterus, but the residual ergot from which it had been extracted seems to possess the echolic powers of the drug unimpaired.

Ergotism, as an epidemic disease, exhibits the poisonous effects of ergoted rye upon a large scale, and in various phases, which probably depend upon the amount of the poison imbibed, as shown by experiments on animals. In one class of cases the cerebro-spinal nervous system is mainly involved, which is indicated by pain, formication and numbness of the extremities, paroxysmal flexures and extensions of the limbs, opisthotonos, violent delirium, etc., symptoms which are succeeded by exhaustion, and sometimes by strabismus, and more or less impairment of vision. In the other class of cases the nervous system is not conspicuously deranged, but the function of nutrition is impaired. A sense of muscular lassitude and a dull hue of the skin precede graver derangements of nutrition shown by the formation of gangrenous areas in various parts of the body. They begin most frequently in the thickness of a limb, and afterwards form on the superficial parts, extending from the fingers or toes upwards, causing these parts to blacken, shrivel, and harden, in a word, to become mummified, or affected with dry gangrene. The dead parts may, as in gangrene from other causes, separate so as to leave a clean wound behind. In a majority of cases, however, the attack is fatal.

In comparing the different grades of the operation of ergot in animals and in man, it is evident that the action in both cases is essentially the same, and that it is manifested mainly by the nervous, and the circulatory functions. The former exhibits debility of the general and special senses, dilated pupils, spinal paralysis, and general convulsions, usually clonic in type. The gravid uterus is thrown into tonic contractions. The circulatory and nutritive functions are shown to be deranged by the slowness of the pulse, the fall of temperature, the cyanosis of vascular parts, the discharge of dark blood, the occurrence of cutaneous eruptions, the shedding of the hair, feathers, etc., and the gangrene of various parts, but in man of the feet and hands especially.

From the preceding observations, it may be inferred that ergot acts primarily upon the nervous system; since the lower degrees of its operation interest exclusively the functions of that system, while its more prolonged action gives rise to radical changes in tissue nutrition. But all the evidence goes to show that the modifications of nervous action are consequent upon a diminished supply of arterial blood to the cerebro-spinal and the ganglionic nerve centres.

This diminished supply of blood is due partly to the sedative operation of the drug upon the heart, and partly to the contraction of the capillaries, which is demonstrable by the ophthalmoscope in the case of the human eye, and is also visible in the frog's foot, and in the membranes of the brain and spinal membranes, and in the spinal cord by the successive muscular spasm and paralysis of the voluntary and also of the intestinal and uterine muscles, and the loss of vitality, with gangrene, which have been alluded to.

Medical Uses. *In Labor.*—Rules have long been in use for the administration of ergot during labor. It may be employed: 1. In lingering labors when the child is low, the parts relaxed, the pains absent or feeble, and there is danger of delay from hemorrhage or other alarming symptoms. 2. When the pains are suspended and convulsions set in, venesection being premised. 3. In inevitable abortion. 4. When the placenta is retained by uterine inertia. 5. In post-partum hemorrhage under like circumstances. The influence of ergot upon the uterus in labor is unlike that of the natural forces; they are intermittent and rhythmical, it is constant and steady, and, as it were, tetanic. After labors with ergot the uterus remains much larger and harder than natural, and that for several days. Ergot has been accused of causing rupture of the uterus, but the evidence is incomplete when it has been administered according to established rules. Disease of the uterus, deformity of the pelvis or spine, and similar conditions forbid its use. No doubt laceration of the perineum and of the os uteri and hour-glass contraction may sometimes be attributed to its imprudent exhibition, as well as prolapse of the uterus or the rectum. Retention of the placenta is even more apt to occur. In some cases also, perhaps from an overdose of ergot, it has appeared to cause delirium, or coma, lividity of the face, muscular rigidity, etc. There is no doubt that ergot is dangerous to the child in proportion to the duration of its action, and that therefore it should not be administered until labor is near its termination. Fatal effects of the drug may occur even when it has not occasioned contraction of the uterus. Children are then born dead, with cyanosed skin and distorted limbs; and the discoloration has followed the use of the oil of ergot, which does not stimulate the uterine contractions. It follows, from these facts, that the rules above stated are justified, and that another might be added to them, viz., never to give ergot to expedite labor in larger doses than are necessary to produce that effect. In premature labor the drug appears to be more hostile to the child's life than at term, but is decidedly profitable to the mother. When the uterus is not in action, ergot does not readily excite its contractions; hence it seldom occasions abortion as a direct effect. Indeed, in certain cases when this accident is imminent from accidental uterine hemorrhage, small and repeated doses of ergot have appeared to prevent it.

Ergot has long been known as a remedy for *uterine hemorrhage* after labor, as well as for *menorrhagia*, and bleeding from *cancer* and other diseases of the uterus. In menorrhagia it seems to be most efficient when the uterus is in a flaccid condition, as shown, amongst other ways, by the persistence of uterine leucorrhœa between the menstrual periods. It doubtless acts in all these cases by contracting the uterine tissue; but that it acts directly upon the bloodvessels is proved by its efficacy in other forms of hemorrhage, *gastric*, *pulmonary*, *nasal*, *intestinal*, *urethral*, *vesical*, and *renal*, and also in *purpura hemorrhagica.* It may be employed in substance, or as fluid extract, by the mouth, or with more prompt effect by the hypodermic injection of ergotin. Full doses should be given. For hypodermic injection a solution may be prepared with 30 grains of ergotin, 13 drachms of water, and an equal proportion of glycerin. One fluidrachm, containing about one grain of ergotin, may be used hypodermically. It does not cause local irritation, and its effect upon the hemorrhage is very prompt.

The power of ergot to contract the uterus sometimes avails to expel retained *placentæ*, *polypi*, *hydatids*, etc. This action, which, under certain circumstances, may be called tonic, has been found efficient in the treatment of uterine *leucorrhœa*, and even of *amenorrhœa* due to an enfeebled and anæmic state. It is stated that ergot moderates the excessive *secretion of milk*, and may be used to prevent *mammary abscess* and the engorgement of the breasts in weaning. It is one of the most efficient remedies in *diabetes insipidus*, associated or not with belladonna. Ergot has long been used with advantage in the treatment of *paralysis of the bladder* and in *paraplegia*. Theoretically it is most appropriate to cases in which hyperæmia of the spinal cord exists, but it would be very difficult, if not impossible, to account for its efficacy in all successful cases upon this ground, particularly since it appears to have been efficacious in reflex as well as in congestive paraplegia. It should be given in full doses to insure its beneficial effects. *Incontinence of urine*, depending either upon irritability of the neck of the bladder or upon enlarged prostate, is palliated or cured, according to the nature of the primary cause. Its power of contracting the blood-vessels has been exemplified in cases of *enlarged spleen* of malarial origin, and even when it occurred as a symptom of leucocythemia. *Uterine tumors* of the fibrous and vascular sort have become reduced under its use. It is claimed, also, that *dilatation of the heart* from impaired nutrition and independent of valvular disease, is greatly benefited by this medicine. It has also been used in *whooping-cough* with apparent success; and for the relief of impaired vision arising from congestion of the *retina* and due to excessive strain of the eye in examining minute objects.

Administration.—Ergot is conveniently administered by making an infusion of one hundred and twenty grains of the drug, coarsely powdered, in about half a pint of hot water, which should be given in tablespoonful doses every ten or fifteen minutes if contraction of the distended uterus is desired, or if hemorrhage from any part is to be checked. The powder may be given in doses of from five to twenty grains at similar intervals. Bonjean's ergotin may be prescribed in doses of from one to three grains under like circumstances. Hypodermically it may be administered in warm water with the aid of glycerin. Ergotin is conveniently taken in gelatin capsules. Slerotic or sclerotinic acid may be administered hypodermically in the dose of from one-twenty-fifth to one-tenth of a grain.

ERIGERON, *U. S.*—ERIGERON.

Fleabane, Philadelphia fleabane, Scabious, E.; *Herbe d'érigeron (de vergerette) de Philadelphie*, F.; *Berufkraut*, G.

The leaves and tops of Erigeron heterophyllum, *Muhl.*, s. E. annuum, *Pers.*, s. E. strigosum, *Bigelow*, and of Erigeron Philadelphicum, *Lin.*, s. E. purpureum, *Ait.*

Nat. Ord.—Compositæ, Asteroideæ.

Origin.—Though the Pharmacopœia recognizes only two species, a third, Erigeron strigosum, *Muhl.* (s. E. integrifolium, *Big.*) inhabits similar localities, and is frequently collected with the former. The three species occur in fields and pastures, and are common weeds in many parts of Canada and the United States; all attain a height of about three feet, begin to flower in June, and are more or less hairy.

Description.—E. PHILADELPHICUM has the radical leaves spatulate, and tapering to a margined petiole, the stem leaves oblong or lanceolate, the upper ones clasping, all somewhat toothed, or the upper entire; the few flower-heads on slender peduncles; the numerous rays almost filiform, pale purple, or flesh-colored, and twice longer than the involucre; the pappus consists of a single row of capillary bristles.

E. HETEROPHYLLUM has roundish, ovate, coarsely dentate, radical leaves upon petioles about twice their length; the stem leaves are ovate-lanceolate or lanceolate, serrate in the middle, the upper ones smaller, narrowed at base, and sessile; the rays are numerous, white, tinged with purple, narrow, and less than twice the length of the involucre; the pappus is double, the outer row consisting of minute scales.

E. STRIGOSUM. The radical leaves are spatulate-lanceolate, petiolate; the stem leaves lanceolate, all nearly entire; the numerous rays white, and twice the length of the involucre; the scanty pappus is double, like the preceding.

The plants are collected in the middle of summer; they have a slight aromatic odor and a bitterish taste. They have not been analyzed with the view of isolating the bitter or diuretic principle. The volatile oil was obtained by F. L. John (1855) to the amount of half a drachm from 45 pounds of the dry herb; it is described by Procter as greenish-yellow, of a penetrating odor, a bitterish, pungent taste, of the spec. grav. 0.946, and more viscid than the oil of Er. canadense.

Medical Action and Uses.—Erigeron is a diuretic, and has been used in the treatment of *dropsies*, and of various disorders of the *urinary organs*. An infusion may be prepared with an ounce of the plant to a pint of boiling water, and given in doses of a wineglassful or more.

ERIGERON CANADENSE, *U. S.*—CANADA ERIGERON.

Canada fleabane, E.; *Herbe d'érigeron (de vergerette) de Canada*, Fr.; *Canadisches Berufkraut*, G.

The leaves and tops of Erigeron Canadense, *Lin.*

Nat. Ord.—Compositæ, Asteroideæ.

Description.—This annual is indigenous to North America, where it is met with as a common weed in fields and waste places; it is now widely diffused over the world. The stem attains a height of five or six feet, but in sterile locations is usually dwarfed, and only a few inches high; it is bristly, hairy, erect, and much branched; the leaves are lance-linear, hairy, and mostly entire; the flower heads are small and numerous, have a cylindrical involucre, many capillary ray florets, which are nearly included in the involucre, and a straw-colored bristly pappus. It flowers from July to October, and should be collected in August. It has an aromatic odor, and a bitterish, somewhat acrid and astringent taste.

The most important constituent is volatile oil (see *Oleum erigerontis*).

Off. Prep.—Extractum erigerontis canadensis fluidum, *U. S.*

Medical Action and Uses.—Canada Erigeron is a stimulant which owes its virtues to a volatile oil that is officinal. It was popularly supposed to have a special action upon the uterus (whence its name "squaw-weed"), and it has been used successfully to arrest *uterine hemorrhage*. It has also been employed to palliate *vesical irritation* and *strangury*, and cure *gonorrhœa*. An infusion may be prepared with an ounce of the plant to a pint of boiling water. *Dose*, a wineglassful. The oil has been used in the dose of five drops repeated at intervals of half an hour to arrest post-partum hemorrhage.

ERIODYCTION.—MOUNTAIN BALM.

Consumptive's weed, Bear's weed, E.

Eriodyction californicum, *Benth.* (E. glutinosum, *Benth.*), s. Wigandia californica, *Hook. and Arn.*

Nat. Ord.—Hydrophyllaceæ.

Origin.—An evergreen shrub, three to five feet high, growing thriftily among the rocks on the mountain ranges of Central California southward to Northern Mexico. It has axillary and terminal racemose clusters of showy purplish-blue flowers, with a funnel-shaped corolla and five stamens, and ovoid, semi-transparent capsules supported by the persistent five-lobed calyx, and containing about twenty seeds. The leaves are employed.

Description.—The leaves are alternate, petiolate, two to three inches long, elliptic-lanceolate, subentire or finely dentate, with the upper surface smooth, green, and varnished with a resinous exudation, and the lower surface white, hairy, and delicately reticulated by a network of veins. After bruising the leaves their balsamic odor becomes more apparent; their taste is aromatic, balsamic, and free from bitterness.

Constituents.—The leaves evidently contain *volatile oil* and *resin.* According to H. S. Wellcome (1876), the latter is transparent, amber-colored, balsamic in odor and taste, amounts to from 20 to 30 per cent. of the leaves, and consists of several distinct resins. The same resin covers also the branches.

Pharmaceutical Uses.—Wellcome has suggested the preparation from it of a fluid extract and a tincture, the latter representing four troyounces to the pint, using 75 per cent. alcohol as the menstruum. By triturating the resin with powdered French chalk, and following the officinal process for syrup of tolu, a syrup is obtained, having a delicious fruity aroma and taste, closely resembling those of the pineapple, due probably to the presence of butyric ether in the resin.

Medical Action and Uses.—Although supposed at first to possess medicinal value, it speedily ceased to attract attention. It was stated to be very serviceable in atonic bronchitis, but worse than useless in the inflammatory form of the disease; and a bold ignorance pronounced it to be a "specific for chronic lung disease, and a certain cure for consumption."

ERYNGIUM.—ERYNGO.

Button snakeroot, Corn snakeroot, Rattlesnake-master, E.

The rhizome of Eryngium yuccæfolium, *Mich.*, s. Er. aquaticum, *Lin.*

Nat. Ord.—Umbelliferæ, Orthospermæ.

Origin.—The plant grows in pine barrens and prairies, from New Jersey westward to Wisconsin and southward to South Carolina. It has grass-like, nerved, and bristly-fringed leaves, the radical leaves being twelve to eighteen inches long, those of the stem much shorter; the white flowers are in dense ovate heads which are larger than the nearly entire leaflets of the involucre. It blooms in July and August.

Description.—Button snakeroot consists of a short root-stock, one-quarter to one-half inch long, with numerous short branches terminating with a more or less deeply cup-shaped scar. A transverse section exhibits a large whitish central pith and several short wood wedges, separated from the bark by a brown cambium line. Below the root-stalk is divided into a large number of thin nearly simple rootlets from two to three inches long, and containing a rather thick and soft whitish meditullium. Button snakeroot has a dark-brown color externally, a slight, but rather heavy aromatic odor, and a sweetish and somewhat aromatic taste, recalling that of parsnep, which is probably due to a volatile oil.

Allied Plants.—ERYNGIUM VIRGINIANUM, *Lam.*, has linear-lanceolate leaves and a spiny-toothed involucre longer than the heads of bluish flowers. It is biennial, and grows in swampy localities in the vicinity of the coast, from New Jersey southward.

ER. CAMPESTRE, *Lin.*, Eryngo, *E.;* Chardon-Roland, *Fr.;* Mannstreu, Brachdistel, *G.* A European perennial. Its root is cylindrical, about two feet long, one inch thick, with several conical heads, brown externally, and with a thick, internally white bark, covering the porous yellowish wood.

Medical Action and Uses.—Button snakeroot has an acrid and aromatic taste, and is reputed to be diaphoretic and expectorant, and emetic in large doses. In Europe E. maritimum was once celebrated for its diuretic virtues, as was also E. campestre. Both species continue to be used in the treatment of *dropsy, gravel,* and *jaundice.*

ERYTHROXYLON.—COCA LEAVES.

Feuilles de coca, Fr.; *Cocablätter,* G.

The leaves of Erythroxylon coca, *Lam.* *Nat. Ord.*—Erythroxylaceæ.

Origin.—Coca is a small shrub about four feet high, with numerous spreading purplish-brown branches. It has small, yellowish, five-petalous flowers in axillary clusters of three or four, ten hypogynous stamens, and an oblong, red and smooth drupaceous fruit containing a single albuminous seed. It is indigenous to the mountains of Peru and Bolivia, and is cultivated in some parts of Brazil and the Argentine Republic. The leaves when collected are carefully dried in the sun, to preserve their green color. About 40,000,000 pounds are annually produced.

Description.—The leaves are alternate, about two inches long, ovate or oval-oblong, rather obtuse and usually emarginate, somewhat narrowed into the short petiole, entire on the margin, rather thin, smooth, with a prominent midrib, on each side of which is a curved line running from the base to the apex. They have a slight but agreeable odor similar to that of tea, and a somewhat bitter and aromatic taste.

Constituents.—Wackenroder (1853) showed the presence, in coca leaves, of a peculiar tannin, which reacts with a green color upon iron salts, and has since been called *cocatannic acid.* Gaedeke (1855) isolated a crystalline alkaloid, which was provisionally named *erythroxylina,* and further examined by A. Niemann (1860) and W. Lossen (1865), the name being changed to *cocaina.* It is obtained from the infusion, which has been freed from tannin by acetate of lead, and rendered alkaline by soda, by agitation with ether and by evaporating the ethereal solution. When pure it is in colorless prisms of a strong alkaline reaction, has a bitterish taste, produces a transient numbness upon the tongue, dissolves in 704 parts of water, and in much less alcohol and ether. Its composition is $C_{17}H_{21}NO_4$, and on being heated with concentrated muriatic acid, it is decomposed into methylic alcohol CH_4O, benzoic acid $C_7H_6O_2$, and *ecgonina* $C_9H_{15}NO_3$, the latter having a sweetish-bitter taste, and is soluble in water, but insoluble in alcohol. Maclagan first observed the presence in coca of a volatile alkaloid, which Lossen named *hygrina;* it was obtained by the latter as a thick pale-yellow oil of a burning taste, a strong alkaline reaction, and an odor resembling that of trimethylamina. The other constituents of coca appear to be of neither pharmaceutical nor medical importance.

History.—Coca was used by the aborigines of South America long before their conquest by the Spaniards. They regarded it as a divine gift, employed it in religious ceremonies, and spoke of it as "that heavenly plant which satisfies the hungry, strengthens the weak, and makes men forget their misfortunes." The first of these reasons was sufficient to render it abominable in the sight of the fanatical invaders, who forbade its use and culture. But when they discovered that it enabled the conquered people to perform the work of their taskmasters, they winked at its diabolical origin and virtues.

Physiological Action. *On Animals.*—It seems to result from experiments that in very large doses coca produces tetanic convulsions; that in much smaller doses it causes hyperæsthesia, dilatation of the pupils, and diminution of movement, apparently from loss of co-ordination; that in intermediate doses it diminishes and then extinguishes sensibility, without destroying motility. According to Bennett, cocaine and the alkaloids of tea, coffee, guarana, and cocoa, produce identical effects, in small doses causing cerebral excitement and impaired sensibility, and in large doses an increase of these symptoms followed by tonic or clonic convulsions. He found that they at first increase and afterwards diminish the force and frequency of the heart's action; that they affect the capillaries by first contracting and then relaxing them; that they slightly lower and then raise the temperature, increase the salivary secretion, etc.

On Man.—Owing to the small quantity of coca, and that often impaired in activity, which is to be procured in countries where physiological research is practised, the conclusions in regard to its action are somewhat deficient in fulness and precision. Its principal effects are manifested in enabling those who use it to remain for a long time without food, and to endure unusual fatigue, and to preserve a cheerful temper. Some of the first historians of its use, as Von Bibra, state that it suspends the appetite for food for some hours, and at the same time greatly increases the muscular strength and endurance. When the proper quantity has been chewed, the laborer goes cheerfully to his work, and gives no heed to meal times while the influence lasts. By repeated doses abstinence from food can be maintained for three or four days. In some persons it produces an exhilarating effect. The celebrated traveller Tschudi, and more recent observers, found that when taken in infusion it conferred a singular immunity from suffering, and prevented the hemorrhages which are apt to occur in the elevated passes of the Andes, some of which are 17,000 feet high. Christison, who tested its action among the Highlands of Scotland, observed that it entirely prevented the fatigue which follows severe pedestrian exercise, and suspended hunger and thirst during its action. It had no effect upon the mental faculties beyond liberating them from the dulness and drowsiness which fatigue occasions. A native of Colombia, however, Posada-Arango, declares that coca has none of the virtues attributed to it; that the use of it by chewing is a mere distraction, like reading, to make the time pass. Bouchardat, also, considers that its virtues are merely such as belong to Chinese tea. And Scrivener reports: "I have seen hundreds of Indians during my residence in Bolivia, who have chewed coca-leaf from youth upwards, many of whom had attained their eightieth year, who showed no signs of being affected by the plant." But a very different account is given by competent witnesses of those who use the plant in excess. It is said to derange the digestion, induce habitual constipation with jaundice, loss of appetite, emaciation, and dropsy. It would seem that mental disorder is not frequent, although foreigners unaccustomed to the plant suffer from delirium and hallucinations (v. Bibra). Other reporters add that the mind is affected with imbecility, and the muscular system with weakness and trembling, and that the circulation becomes slow, feeble, and intermittent. It may safely be assumed that coca, like alcohol and tobacco, may be useful or poisonous, according to the quantity taken and the manner of using it.

So far as experiments have been undertaken, they do not agree in their physiological results. Ott found that during the use of coca for five days the solid elements of the urine diminished, while the weight of the body slightly increased. During the experiment, the urine contained oxalate of lime. Christison found that it increased the saliva, and probably lessened the secretion of the urinary solids. Gazeau, on the other hand, found that it augmented the excretion of urea and lessened the weight. According to him, its power consists in its sustained excitation of the vital functions, along with an anæsthetic power which lessens the sense of fatigue and hunger. The former conclusions are the more reasonable.

When the alkaloid *cocaïna* is given to rabbits by the stomach, it only slightly disturbs the heart's action or the respiration; but hypodermically administered even in small doses, it occasions, according to Schroff, violent tonic spasms, extreme dilatation of the pupil, and an increased pulse and respiration rate. The experiments of Bennett, on the other hand, performed on frogs and rabbits, show that its direct tendency is to cause spinal paralysis and loss of reflex action. In experiments on himself with this alkaloid, Schroff found that it quickened the pulse and occasioned an agreeable sense of lightness and activity in the mind and body, followed by some lassitude and an inclination to sleep.

In its native country, Colombia, coca is used, precisely as Chinese tea is elsewhere, as a mild stimulant and diaphoretic and an aid to digestion. These are mainly the purposes of coffee, chocolate, and guarana; and experiment has proved that the active principles of all these productions, "although unlike one another and procured from totally different sources, possess in common prominent principles, which are not only almost identical in chemical composition, but also appear similar in physiological action." (Bennett.)

Medical Uses.—Coca has been gravely proposed as a means of appeasing hunger and thirst in armies on forced marches and on voyages with insufficient food and water, the fact being overlooked that hardly enough of it has hitherto been procurable for laboratory experiments; and also that tobacco, coffee, and tea, which are abundant, have closely analogous virtues. It has also been proposed for allaying the canine hunger observed in some cases of *epilepsy* and *insanity*, and to appease the thirst in *diabetes*. Opium has generally been used to fulfil these indications. In *melancholia* it may be employed as opium and also cannabis have been, and probably with as little real advantage. It is said to have been used in South America to overcome *uterine inertia*, and to allay pain and the discharges in *cholera morbus*. It is reported to have been useful in *spermatorrhœa* and *generative debility*, but no proof exists of so improbable a statement.

Administration.—The Indian coca-chewer always carries a bag of the leaves hanging from his neck, and a small flask filled with ashes or lime. After having withdrawn the filaments from a handful of leaves, he chews them until they are reduced to a pulp; this he forms into a ball which he pierces with a splinter wetted and covered with adhering ashes. The mass has then acquired a pungent taste which excites copious salivation; a part of the saliva is ejected and a part swallowed. The ball is retained in the mouth for about an hour, and then is renewed with a fresh handful of leaves. For medicinal purposes, the most convenient form is an infusion made with about two drachms of the leaves in four fluidounces of water. Of cocaïne the *dose* is stated to be from one-eighth of a grain to one grain, in substance or as an acetate or muriate.

ESSENTIÆ.—ESSENCES.

Alcoolés concentrés, Fr.; *Essenzen*, G.

Two preparations of this class have been admitted in the British Pharmacopœia. They are simply solutions of volatile oils in alcohol, and are therefore identical with, except that they contain a much larger amount of volatile oil than, the officinal spirits. The volatile oils are in France usually termed *essences*, while the spirits containing volatile oils, but prepared by distillation, are called *alcoolats;* and those made by simple solution of volatile and non-volatile substances, are known as *alcoolés.* The *Essenzen,* popularly so called in Germany, are often strong tinctures or strong solutions of volatile oils, or mixtures of the two.

ESSENTIA ANISI, *Br.*—ESSENCE OF ANISE.

Alcoolé d'anis concentré, Fr.; *Anisessenz,* G.

Preparation.—Take of Oil of Anise one fluidounce; Rectified Spirit four fluidounces. Mix. *Br.*

Medical Action.—For medical uses *see* Spiritus anisi.

ESSENTIA MENTHÆ PIPERITÆ, *Br.*—ESSENCE OF PEPPERMINT.

Alcoolé de menthe poivrée concentré, Fr.; *Pfefferminz-Essenz,* G.

Preparation.—Take of Oil of Peppermint one fluidounce; Rectified Spirit four fluidounces. Mix. *Br.*

Medical Action.—For medical uses *see* Spiritus menthæ piperitæ.

EUCALYPTUS.—EUCALYPTUS LEAVES.

Feuilles de l'eucalyptus, Fr.; *Eucalyptus-Blätter,* G.

The leaves of Eucalyptus globulus, *Labill.* Bentley and Trimen, Med. Plants, 109.

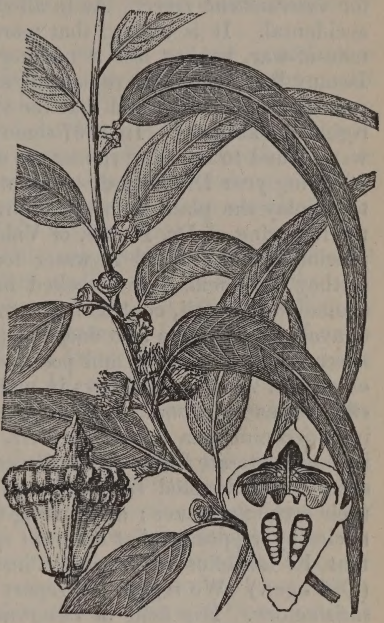
Nat. Ord.—Myrtaceæ.

Origin.—This is the *blue gum-tree* of Tasmania, which was discovered by Labillardière in 1792. It grows on moist slopes of wooded hills in the southern half of that island, and in Victoria on the main-land of Australia; it was introduced into Europe in 1856, and has since then been very extensively planted in the southern part of Europe, in Northern Africa, in the Southern United States, and in California. It is a rapid grower, and attains a height of 200 and occasionally even of over 300 feet. The flowers are upon short and broad axillary peduncles, either solitary or in clusters of 2 or 3. The buds are covered with a whitish bloom, and consist of a top-shaped, ribbed, and warty calyx-tube covered by a so-called operculum, which is composed of the united petals, is hemispherical in shape and prolonged into a cone, and separates entire like a lid from the calyx-tube. The flowers are hermaphrodite, with numerous stamens inserted on a disk, a short style, and a 4- or 5-celled ovary united with the calyx-tube.

Description.—The leaves of young plants are opposite, shortly petiolate, broadly oval or oblong, rather obtuse, heart-shaped at base, and of a pale bluish-green color. They are not employed medicinally. Older trees have the leaves alternate, petiolate, falcate, lanceolate, or oval lanceolate; oblique at the base, very entire, and above gradually tapering to the acute apex. They have a length of 6 to 12 inches, are thick, leathery, and of a pale yellowish-green color, contain numerous pellucid oil-glands, and have, besides the prominent mid-rib, two lateral veins near the margin. The leaves have a peculiar strong balsamic odor, and an aromatic, bitterish, pungent taste, followed by a sensation of coolness.

Constituents.—Hartzer (1876) obtained from the leaves tannin, cerylic, or an allied alcohol, a crystallizable fatty acid—the sodium salt of which is soluble in ether—and three resins, one of which has acid properties, and yields with sulphuric acid a carmine-colored copulated acid, becoming violet with ether. E. S. Wayne (1876) likewise isolated an acid resin, which he found to be crystallizable and to give a brown-red reaction with ferric chloride. The most important constituent, however, is the dextrogyre volatile oil, which was examined by Cloëz (1870) and by Faust and Homeyer (1874). Cloëz regarded the oil as being chiefly composed of *eucalyptol*, $C_{12}H_{20}O$, boiling at 178° C. (352.4° F.), and yielding with phosphoric anhydrid two compounds, $C_{12}H_{18}$, of which *eucalyptene* boils at 165° C. (329° F.) and *eucalyptolene* at above 300° C. (572° F.). Faust and Homeyer, however, obtained from the oil about 60 per cent. of a *terpene*, $C_{10}H_{16}$, boiling between 172° and 175° C. (342.6° and 347° F.), 30 per cent. of *cymol*, $C_{10}H_{14}$, the remainder being a *terpene* boiling at 150° C. (302° F.), and an oxygenated compound, probably $C_{10}H_{16}O$, which they named *eucalyptol*, Cloëz's compound of the same name being a mixture of the first two hydrocarbons, which rapidly combine with oxygen.

Fig. 64.



Eucalyptus globulus, *Labill.*—A flowering branch, an unexpanded flower and longitudinal section of same.

Physiological Action. *On Animals.*—The real action of this medicine is yet to be determined, for the reported results of experiments are the reverse of harmonious. While one observer states that the oil and the extract do not appear to occasion any special phenomena, unless they, perhaps, increase the appetite, another declares that, in pigeons and rabbits, the former gives rise to general excitation, and in excessive doses may prove fatal by paralyzing the excito-motor function, like bromide of potassium, rendering respiration irregular and intermittent, and at last suspending it before the heart ceases to beat. According to Siegen, it depresses the temperature even more than quinia; for twenty grains of the oil caused a rabbit's temperature to fall 3° F., and one hundred and twenty drops caused the evening temperature of a healthy man to fall nearly 1° F.

On Man.—When the oil is taken internally it excites a sense of warmth in the fauces and stomach, with increased salivation, and subsequent eructations of gas; but in doses of from fifteen to twenty grains it is readily tolerated. It is apt to cause some fulness of the head and vascular excitement. It seems to be eliminated through the lungs. It does not impart to the urine a peculiar odor, unless given in tincture and in large doses, and no resinous matter is detected in the urine by nitric acid, as is the case when copaiva is taken. According to Guibert, it eliminates an enormous proportion of urea. We are informed also by him that in doses of twenty drops the oil causes general stimulation, a feeling of lightness, and an irresistible desire to keep moving, together with a remarkable suppleness of the back and limbs. The spirits are raised, and the mind is clear and active; the appetite is increased, and sometimes aphrodisiac effects are observed. To use this author's words, "there is a true medicinal intoxication," which is not followed by a corresponding depression. In doses relatively or absolutely excessive, there is more or less general muscular paresis, without mental depression, and easily dissipated by coffee or alcohol. It is theoretically held to promote the capillary circulation by dilating the capillaries, and thereby rendering the pulse more frequent. Applied to the raw skin it causes burning pain.

Medical Uses.—Eucalyptus has been very extensively used as a remedy for *intermittent fever.* As in all similar cases, the discovery of its virtues was accidental. It is alleged that more than forty years ago the crew of a French man-of-war, having lost a number of men with "pernicious fever," put into Botany Bay, where the remaining sick were treated with eucalyptus, and rapidly recovered. It is also said that the virtues of the tree were well known to the aboriginal inhabitants. In 1867 some peasants of the Spanish province of Valencia were found to be using the leaves of the plant to cure fever and ague. In the following year Dr. Brunel, of Montevideo, was led by reports of this experience to employ the plant in hospital practice, and especially by such statements as the following of Dr. Ramel, of Valencia: "I assure you that four leaves of this precious plant infused in water form an excellent febrifuge. The sick as soon as they find themselves attacked hasten to procure these leaves, and in no instance do they fail, contrasting strongly with cinchona, which not only is often unavailing, but often also does not prevent a relapse." The report of Dr. Brunel is scarcely less glowing and positive. In 1871 Dr. Keeler, an official physician of certain Austrian railways in malarious districts, affirmed that it was quite as efficient as cinchona. Others have attributed to it marvellous results in cases in which cinchona failed. Others, still, conclude that it is peculiarly curative in the inveterate forms of the disease. There were not wanting, however, physicians who doubted the published reports, some of them upon the ground of their own experience; and among these, one, at least, accounts for the discrepancies by supposing that different species of eucalyptus had been employed, and that E. latifolius is generally insufficient, while E. longifolius seldom fails. (Oeffinger.) We regard the report of Burdel as probably the most accurate and satisfactory. His field of observation was in one of the most marshy departments of France, La Sologne, where periodical fevers are exceptionally rife and grave. He put the alleged remedy to a prolonged and thorough test, and concluded that it possessed little or no curative power over intermittent fever. Out of 123 cases only 11 were cured without relapse, and these were, moreover, treated in a hospital; and it is well known that intermittent fever patients, on being removed from a malarial locality, are very apt to recover without any medicinal treatment at all. And still further, it was observed that, among those whose paroxysms ceased under the use of this medicine, there was no diminution of the malarial cachexia such as usually takes place under the treatment by quinia. On the whole, there does not appear to be any substantial reason for believing that a substitute for cinchona has been found in eucalyptus.

It has been alleged that this tree has a special power of destroying malaria in the localities where it grows; but as the statement still lacks confirmation, it is unnecessary to refute the causes assigned for this effect, viz., "that its dead leaves, etc., raise the soil; that it energetically absorbs the soil-water in consequence of its very rapid growth and the multitude of stomata that stud its leaves; and finally, that it protects the soil against the extreme solar heat so favorable to the generation of animalculæ." (Gubler.) These reasons would be equally valid as proofs of its power to generate malaria.

As a summary of the virtues claimed for this medicine, the following may be cited: "Not being an irritant it may be liberally used in all cases of hospital gangrene and other gangrenous affections, of fetid suppuration such as occurs in glanders, syphilis, abscesses connected with dead bone, etc. It may be used with advantage to prevent animal and vegetable putrefaction, and hence as a deodorizer of hospital wards. Internally, it may be given in all cases of ulcer of the stomach or bowels, in septicæmia, typhoid fever, scarlatina, pulmonary gangrene, fetid bronchitis, etc." And as a rationale of its mode of action we are told that if a person is kept under the influence of its oil, the blood drawn from his veins will not undergo putrefaction. "At all events the hæmatoglobulin is expelled from the globules and becomes oxidized externally to them, and the anatomical element is, as it were, embalmed." It is somewhat difficult of conception that the sick of any disease should profit by the mummification of their blood-corpuscles.

Undoubtedly eucalyptus, and especially its oil, tend to restrain putrefactive fermentation, as all aromatics have done since the beginning of history; and very possibly these new agents may excel the old in this respect. Certain it is that the oil is a most efficient deodorizer, and, having a very agreeable odor of its own, is capable of substituting a pleasant for an offensive smell, while its stimulant operation upon diseased tissues assists them in recovering a natural mode of action. It has been inhaled with great advantage in an atomized solution in cases of *gangrene of the lung* and of *fetid bronchitis.*

Its astringent and balsamic qualities naturally suggested its use in the topical treatment of various affections in which other medicines of like qualities had been found useful, especially in alcoholic tincture. Indeed, it cannot be doubted that the alcohol had a potent influence in the treatment by tincture of eucalyptus of slight *hemorrhages, mucous profluvia, leucorrhœa, gonorrhœa,* indolent and irritable *ulcers, spongy gums,* etc. In certain of these affections, especially in *ulcers,* the fresh bruised leaves deprived of their nerves have been found to cause sufficient stimulation to promote a cure.

It is said that smoking the dried leaves of eucalyptus in a pipe or cigar is, with the exception of hypodermic injections of morphia, the most efficient means of calming irritation and procuring sleep in cases of *cardiac* and *aneurismal asthma,* particularly in cases of pressure on the vagus or its branches by thoracic aneurisms. (Maclean.) When the patient is too ill to inhale actively, he may be kept in an atmosphere filled with the smoke of the burning leaves. The tincture of eucalyptus is said to remove the fishy flavor and smell from *cod-liver oil* when added in the proportion of one part to one hundred. The leaves are strown among woollen clothing to protect it from *moths.*

Administration.—The leaves may be applied fresh and bruised, or mixed with poultices. They may be given internally in doses of five grains or more, but efficient doses of them are too bulky for convenient use in this manner. The extract is very apt to derange digestion and occasion diarrhœa. The *dose* of the oil may be stated at from two to five drops. The tincture is the most agreeable form of the medicine; it may be prescribed in doses of fifteen or more minims.

EUPATORIUM, *U. S.*—THOROUGHWORT.

Herba eupatorii perfoliati.—Boneset, Indian sage, E.; *Herbe d'eupatoire perfoliée, Herbe à fièvre, Herbe parfaite,* Fr.; *Durchwachsener Wasserhanf,* G.

The leaves and tops of Eupatorium perfoliatum, *Lin.*, s. E. connatum, *Mich.*, gathered after flowering has commenced.

Nat. Ord.—Compositæ, Asteroideæ.

Description.—Thoroughwort inhabits damp soil and low swampy grounds in Canada and the United States. It is a hairy perennial, with an erect stout stem 2 to 4 feet high, and much branched at the summit; the leaves are opposite, tapering, lanceolate, 4 to 6 inches long, united at the base, with the margin crenately serrate, rugosely veined, rough above and minutely resinous dotted beneath. The flowers are in dense level-topped corymbs; the heads have an oblong involucre consisting of lance-linear scales, and contain 10 to 15 tubular white florets with a bristly pappus in a single row. Its flowers appear in July, and it continues to bloom until September. The leaves and the flowering tops with the small branches are collected in July. It has a rather weak aromatic odor, and a somewhat astringent and persistently bitter taste.

Constituents.—Boneset contains a minute quantity of volatile oil, some tannin, and a bitter principle which has not been isolated. The analyses of W. Peterson (1851) and M. H. Bickley (1854) elicited, besides those mentioned, the usual common constituents of herbs.

Off. Prep.—Infusum eupatorii, *U. S.*

Allied Species.—Most of the numerous species of eupatorium and of some allied genera appear to possess similar properties, and are occasionally employed in regular or domestic practice. The following may be mentioned:—

EUP. TEUCRIFOLIUM, *Willd.*, s. E. verbenæfolium, *Mich.*, s. E. pubescens, *Pers.*, grows from Massachusetts to Louisiana, and is characterized by lance- or oblong-ovate leaves, which are truncate below, coarsely toothed towards the base, and are alternate on the branches. It is popularly known as *wild horehound*, like the nearly allied *Eup. rotundifolium*, Lin., which is found in similar localities, and is mainly distinguished by its roundish-ovate and slightly heart-shaped leaves.

E. FŒNICULACEUM, *Willd.*, called *dog-fennel*, is a common weed in fields and damp places, from Virginia to Florida, with the leaves pinnately dissected into filiform segments. The juice is used for relieving pain from the bites of insects.

E. INCARNATUM, *Walt.*, of the Southern United States from Texas to North Carolina, has triangular ovate, long-petioled leaves, and is used in Texas under the name of *mata* for flavoring tobacco.

E. PURPUREUM, *Lin.*, is common in low grounds, with a tall, simple, purplish-colored or spotted stem, ovate or lanceolate petiolate leaves in whorls of 3 to 6 and dense corymbs of mostly purplish flowers. It is known as *trumpet weed* and *gravel root*, the root being popularly used in various ailments of the urinary organs.

E. CANNABINUM, *Lin.*, or *water-hemp*, is indigenous to Europe; the leaves resemble hemp leaves, but are mostly trifoliate; the root and leaves have diuretic, and in larger doses, emetic properties.

E. AYAPANA, *Vent.*, of Brazil, has dark green leathery leaves, with purplish veins and a coumarin-like odor. It is an aromatic tonic.

MIKANIA GUACO, *H. B.*, a native of Colombia and the West Indies, is an aromatic, bitter, climbing herb, 20 feet long, with the leaves ovate-elliptic and rusty tomentose beneath; it was at one time highly lauded as a remedy in cholera and in hydrophobia. Its medicinal properties are probably not superior to those of *Mik. scandens*, Lin., of the United States, which has nearly triangular heart-shaped leaves. The genus Mikania is closely allied to eupatorium, not only botanically, but also in its sensible properties.

Medical Action and Uses.—Eupatorium resembles chamomile in its effects. It is a stimulant tonic in small, and a laxative in large doses, and an emetic or diaphoretic in warm infusion. Like all such plants, it is used to prevent or to break the chill in *intermittent fever* of a mild type. A hot infusion is a popular and efficient remedy in the forming stage of *muscular rheumatism*, *sore throat*, *bronchitis*, and even *influenza*. Its power of relieving pain in the limbs in the last-named disease entitled it to the popular name of boneset. In atonic *dyspepsia* its effects resemble those of other bitter tonics. The *dose* of the powder is stated to be twenty or thirty grains. The officinal infusion is the most convenient form for administering the medicine.

EUPHORBIA COROLLATA, *U. S.*—LARGE-FLOWERING SPURGE.

Wild ipecac, Wild hippo, E.; *Racine d'euphorbe à grandes fleurs,* F.; *Grossblüthige Wolfsmilch-Wurzel,* G.

The root of Euphorbia corollata, *Lin.* *Nat. Ord.*—Euphorbiaceæ.

Origin.—A smooth, perennial plant, which is met with in low, sandy, and dry soil from Canada to Florida, and west to Mississippi, and is abundant in many localities, chiefly of the Southern and Western States. It produces a slender, nearly simple stem two to three feet high, which has the leaves, excepting the floral ones, alternate, linear-oblong, and obtuse. The flowers are in umbels of five to seven rays, each one being again two or three-forked, and are conspicuous for the showy white appendages to the involucre, which have the appearance of petals, and bear a greenish gland at the base. The smooth capsule separates at maturity into three carpels, each containing a single ash-colored seed. It flowers in the latter part of summer and in autumn, when the root should be collected. This, like the next root, appears to be rarely met with in the market; we have received instead of it the roots of Gillenia stipulacea, Triosteum perfoliatum, and of other plants.

Description.—The root is 1½ to 2 feet long, and, when full grown, about an inch thick, cylindrical, and little branched; is externally of a dark-brown, or, when old, of a blackish color; has underneath the thin corky layer, a thickish white bark, which incloses a spongy, porous, whitish wood, radially striate by many medullary rays. In the dry state it is longitudinally wrinkled, and breaks with a short, nearly smooth fracture. It is inodorous, and has a sweetish, afterwards warm taste.

Constituents.—The emetic principle of this root is still unknown. It is probably similar to the next.

Medical Action and Uses.—Large-flowering spurge is reputed to possess emeto-cathartic properties, and its contused root will vesicate the skin. Hence it cannot be a safe agent in cases of gastro-intestinal irritation, and there seems to be no sufficient reason for its encumbering even the secondary list of the Pharmacopœia. *Dose,* as an emetic, twenty grains; as a cathartic, ten grains; as a diaphoretic, five grains.

EUPHORBIA IPECACUANHA, *U. S.*—IPECACUANHA SPURGE.

Carolina ipecac, Carolina hippo, E.; *Racine d'euphorbe vomitive,* Fr.; *Brechwolfsmilch-Wurzel,* G.

The root of Euphorbia ipecacuanha, *Lin.* *Nat. Ord.*—Euphorbiaceæ.

Origin.—A smooth, perennial, herbaceous plant, of a dull-green or dark-purplish color, growing in barren, sandy soil, at a limited distance from the sea-shore from Connecticut southward to Georgia. It produces several ascending or often diffusely spreading stems, which fork from near the base, and have opposite, obovate or oblong, obtuse, and entire, nearly sessile leaves. The flowers are inconspicuous, long-peduncled, and appear singly from the forks or the axils of the upper leaves. The nearly smooth capsule contains in each of its three cells one white, somewhat dotted seed. It flowers during the spring months.

Description.—The root resembles the preceding in general characters, but is thinner, has externally a gray or yellowish-brown corky layer, which is never blackish or dark-colored, and shows internally a yellowish, porous wood. Odor and taste are similar to the preceding. Barton believed it to be equally efficacious throughout the year.

Constituents.—The latest analyses by Petzelt (1873), and Dilg (1875), failed to add much of importance to the older one of Bigelow, except that the abundant presence of starch was proven. Petzelt regards the resinous portions as containing the emetic principle. The root may possibly contain a glucoside, since Dilg did not get a reaction for glucose until the decoction had been boiled with an acid. *Euphorbon* was found among the products extracted by petroleum benzin.

All species of Euphorbia contain a milky juice, and appear to be endowed with cathartic and emetic, frequently very acrid properties; many are occasionally employed medicinally. *E. hypericifolia* and *maculata*, Lin., are known in some parts of the United States as *spotted eyebright*, the oblique leaves being often marked with a red or brown spot; they have been used in some affections of the eye, and internally in diarrhœa, amenorrhœa, etc.

Medical Uses.—Ipecacuanha spurge does not differ essentially from the other officinal species. It may be used under the same conditions and in similar doses.

EUPHORBIUM.—EUPHORBIUM.

Euphorbe, Gomme-résine d'euphorbe, Fr.; *Euphorbium*, G.

The gum resin obtained from Euphorbia resinifera, *Berg.* Bentley and Trimen, Med. Plants, 240.

Nat. Ord.—Euphorbiaceæ.

Origin.—The plant is indigenous to the lower slopes of the Atlas Mountains of Morocco. It has an ascending, cactus-like, fleshy, quadrangular stem with spreading branches, and, instead of leaves, is furnished with divergent, spinescent stipules, situated in pairs on the angles; the flowers are in pedunculate cymes of three, or rarely more. On wounding the branches a milk-juice exudes, which hardens upon the plant, usually encrusting the spines. While it is being collected, the mouth and nostrils are protected by a cloth from the irritating effects of the dust.

Description.—Euphorbium is seen in roundish, somewhat three-cornered, cylindrical, or irregular pieces varying considerably in size, the largest measuring nearly an inch. The shape is influenced by the portion of the plant around which the exudation is hardened, and most pieces are observed with one or more holes, and inclosing fragments of the spines, flowers, or fruit. Euphorbium is brownish-yellow, somewhat translucent, brittle, nearly inodorous; but the dust excites violent sneezing, and, if inhaled, acts as an acrid poison. The taste is at first slight, afterwards burning and acrid. When heated it gives off a faint odor, suggesting that of benzoin, afterwards fuses and burns with a bright, sooty flame.

Constituents.—The older analyses by Braconnot, Brandes, and others, seem to indicate that euphorbium varies to some extent; the *resin*, readily soluble in cold alcohol, and possessing an extremely burning taste, varied between 37 and 44 per cent.; Flückiger (1868) obtained 38 per cent. of it, and ascertained its composition to be $C_{20}H_{32}O_4$. The sparingly soluble, crystallizable resin of Bonastre and others was named *euphorbon* by Flückiger, who obtained 22 per cent., and gave it the formula $C_{26}H_{44}O_2$. It is soluble in ether, benzol, amylic alcohol, chloroform, acetone, glacial acetic acid, and hot alcohol, but requires about 60 parts of alcohol for solution at the ordinary temperature. When the last traces of the acrid resin have been destroyed by boiling in a weak solution of potassium permanganate, it is entirely tasteless. If its alcoholic solution is allowed to evaporate until it forms a thin film, and this is moistened with strong sulphuric acid, the slow addition of a little strong nitric acid produces a fine violet color, a reaction which is also observed with lactucerin. Flückiger obtained also 12 per cent. of *malates*, chiefly of calcium and sodium; 10 per cent. of *mineral compounds*, and 18 per cent. of *gum*, which is precipitated by acetate of lead, also by silicate of sodium and borax.

Physiological Action.—The extremely acrid qualities of euphorbium were known to the ancients, for both Pliny and Dioscorides describe the mode of collecting the juice so as to prevent its irritating emanations from affecting the face or hands. They also speak of its taste as persistently hot and acrid, drying the throat. Its dry powder does not affect the sound skin usually, but it irritates the mucous membranes, and causes the eyes to weep and grow red, the nose to run with watery and even bloody mucus, and saliva to flow abundantly from the mouth. To prevent these effects, says Pereira, some drug grinders employ masks with glass eyes, others apply a wet sponge to the nose and face, while others cover the face with crape. Individuals who have been exposed for some time to the influence of this dust, suffer with headache, giddiness, and ultimately become delirious. I was informed, he adds, of an Irish laborer who was made temporarily insane by it, and who, during the fit, insisted on saying his prayers at the tail of the mill-horse. In a case which fell under his notice, a man grew suddenly delirious, and presently became insensible and fell in a fit. His face was red and swollen, his pulse frequent and full, and his skin very hot. On being bled, his consciousness returned, and he complained of great headache. Internally it causes great thirst, dryness of the throat, colic, vomiting, and purging, and in excessive doses besides these symptoms cold sweats, syncope, thready pulse, and even inflammation and gangrene of the bowels.

Medical Uses.—Although euphorbium was anciently and even in comparatively modern times used as a drastic purgative in *dropsy*, yet the extreme harshness of its operation led to its being associated with milder drugs for the same purpose, and at the present day it is never given internally. It was also at one time applied as a local stimulant in certain cases of *paralysis*, and more recently as a *sternutatory* when mitigated with inert or mild powders. As a local irritant, it has been used in the same cases for which mezereon is employed; and particularly in plasters intended to prolong *suppuration*, as in cases of obstinate *sciatica*. In ointments it was applied to *ulcers* maintained by necrosed bone. Plasters containing it have also been used in the treatment of chronic swellings of the *joints* induced by scrofula, gout, or rheumatism.

ERYTHROPHLŒUM.—SASSY BARK.

Mancona bark, *Saucy bark*, E.; *Écorce de mançône*, Fr.; *Mancona-Rinde*, G.

The bark of Erythrophlœum guineense, *Don.* (E. judiciale, *Procter*); s. Fillæa suaveolens, *Guill.* and *Per.*

Nat. Ord.—Leguminosæ, Cæsalpineæ.

Origin.—Sassy bark comes from a large tree with bi-pinnate coriaceous leaves, terminal compound spicate racemes of decandrous flowers, and flat legumes with three or four lenticular seeds. The tree grows in Central and Western Africa, and the bark is used by the natives as an ordeal and an arrow poison.

Description.—The bark is seen in flat or curved pieces of irregular size, covered externally with an uneven fissured corky layer, or deprived of the same, of a dull red-brown color. It is hard, brittle, of a fibrous texture, internally with pale yellowish-brown spots, inodorous, of an astringent taste, and when powdered excites violent sneezing.

Constituents.—Sassy bark contains tannin and a red derivative of it, and yields its active principle to water and alcohol (Procter, 1852). Gallois and Hardy (1876) isolated the poisonous constituent by treating the aqueous extract of the alcoholic extract of the bark with an alkali, and exhausting the mixture with acetic ether. This alkaloid, *erythrophleïna*, is colorless, crystalline, soluble in water, alcohol, amylic alcohol, and acetic ether, but nearly or entirely insoluble in ether, chloroform, and benzol. With sulphuric acid and potassium permanganate a violet coloration is obtained, less intense than the one produced by strychnia, and soon changing to dirty brown. The solutions of its salts are precipitated by the usual reagents for alkaloids, including bichromate of potassium, which yields a yellowish precipitate.

Erythrophlœum couminga or *koumanga* is also a large tree, all parts of which are poisonous, containing an alkaloid which is closely related to erythrophleïna, if not identical with it.

Physiological Action. *On Animals.*—The first systematic experiments with sassy bark were made in Philadelphia, in 1859, by Drs. S. Weir Mitchell and W. A. Hammond. The most conspicuous effect was a general muscular resolution, such that the animal would remain quiescent in whatever position he was placed, even until death in some instances, without exhibiting any evidence of suffering. Indeed, a degree of anæsthesia was observed. If disturbed, the animal speedily recovered his activity and sought to escape, although his efforts were marked by a certain languor and difficulty which brought him to rest again almost immediately. When a fatal dose was administered, the head fell and was caught up again, and at last reposed upon the fore paws; vomiting usually took place, the pupils contracted, the heart became slow and irregular, the respiration quick and labored, and at length death occurred with general convulsions and sudden dilatation of the pupils. Upon examination, the membranes of the brain were found to be highly congested, but there were no other peculiar changes. In 1876 was published an account of experiments with casca bark performed by Drs. Bruxton and Pye, and which agree with the statement above given; for these authors say, "In cats and dogs it causes restlessness and nausea succeeded by violent and repeated vomiting. The respiration is very much quickened. The first symptom of any affection of the locomotor organs in cats is a peculiar jerk of the hind limbs, as if something were sticking to the feet, and the animal was trying to shake it off while walking; then the gait becomes staggering, and the animal ceases to be able to stand. Death generally occurs during a convulsion of an emprosthotonic character, apparently connected with an attempt to vomit. Consciousness seems to be preserved to the last."

In 1876 MM. Gallois and Hardy discovered in sassy bark and leaves an alkaloid with which they experimented and obtained the following results. It is a heart-poison. Two milligrammes injected under the skin of a frog arrest the heart in systole in from five to eight minutes; the voluntary muscular movement and irritability remaining unimpaired for several hours. In warm-blooded animals the alkaloid excites convulsive shocks and extreme dyspnœa as consequences of the disorder in the circulation of the blood, *i. e.*, of the heart's arrest. After the animal's death this organ is found distended with blood. During the progress of the poisoning the pulse is alternately accelerated and retarded; in the latter state it becomes fuller, in the former small and feeble. Although the heart muscle is the first to die, the voluntary muscles are, nevertheless, in their turn paralyzed. In these experiments no mention is made of paralysis as a symptom of the poisoning, nor yet of vomiting or diarrhœa.

On Man.—The accounts which were long ago received of the effects produced by the sassy ordeal agree in certain points but not in others. In most of them the production of vomiting appears to be the capital phenomenon, for upon its occurrence or non-occurrence the accused was held to be innocent or guilty. "It is supposed that the fetish goes down with the water into the man's stomach, and looks about in his heart for the guilt; that if he discovers the prisoner to be innocent, he comes back with the draught which is vomited up again; but if he finds the alleged guilt, he remains in the stomach with the water to inflict merited chastisement upon the culprit." According to another account the accused, after the trial, "is obliged to move his arms and legs, to show that he has not lost the use of them;" and Santas, who first analyzed this bark, states that the sufferer "loses the power of contracting the muscles throughout the body, he is incapable of standing or walking, and the head rolls heavily about the breast and shoulders." Rev. J. L. Wilson, an American missionary, who published his observations on Western Africa in 1854, describes under the name of "nkazya" an ordeal poison, of which he says: "If it act as a diuretic it is a mark of innocence; but if as a narcotic, causing dizziness or vertigo, it is a sure sign of guilt. Small sticks are laid down about eighteen inches or two feet apart, and the suspected person, after he has swallowed the draught, is required to walk over them. If he has no vertigo this is an easy task, but if his brain is affected, he imagines they rise up before him like great logs, and he is then apt to step awkwardly and fall down, whence he is at once concluded to be guilty." In the article *Akazga* the effects of that poison are described almost in the same words, except that tetanic spasm is substituted for vertigo, in the description. But, on the whole, sassy and akazga seem to be antagonistic; the one is a relaxing the other a tetanizing poison.

According to Drs. Brunton and Pye, the vomiting produced by sassy occurs, whether it be given internally or hypodermically, but purging only in the former case. The paralysis it causes they explain as being due not to a direct action upon the muscles, or the motor nerves, or the spinal cord itself, but to the contraction of the bloodvessels which lessens the supply of blood to these parts. It acts directly upon the ends of the vagus nerve in the heart, and also upon the nerve itself, and much in the same manner as digitalis. But the final slowing of the heart produced by large doses of casca is due to the action of the drug upon the ganglionic apparatus contained in the heart itself. It has "a most extraordinary power of contracting the bloodvessels," not as digitalis has by stimulating the vaso-motor centre in the medulla-oblongata, but by acting either on the bloodvessels themselves, the vaso-motor nerves, or the vaso-motor centre not contained in the medulla. It appears to act as a diuretic by contracting the arteries, and so increasing the blood pressure. It will be noticed that in the description of "nkazya" by Wilson, given above, diuresis is mentioned as one of its effects.

Medical Uses.—When, in 1859, the essay referred to was published, it had an appendix describing the medicinal applications of sassy. It is said to be astringent, narcotic, acrid, cholagogue, and diaphoretic, and to be used successfully in the treatment of *periodical fevers*, *colic*, *diarrhœa*, and *dysentery*. A summary of cases of the last-named disease treated by the medicine appears to demonstrate its possession of marked curative virtues. It was given in tincture and also in extract. While these clinical reports point in one direction, physiological reasons are now given for using the medicine in *cardiac dropsy*, especially when it depends on mitral obstruction, and in cases of *hemorrhage* due to flaccidity of the capillaries.

EUONYMUS, *U. S.*—WAHOO.

Cortex euonymi.—Spindle tree, Burning bush, E.; *Écorce de fusain (de bonnet de prêtre)*, Fr.; *Spindelbaum-Rinde*, G.

The bark of Euonymus atropurpureus, *Jacq.* *Nat. Ord.*—Celastraceæ.

Origin.—The wahoo is a shrub 6 to 10 or even 14 feet high, and is found in shady woods of the northern and middle section of the United States east of the Mississippi. As an ornamental shrub, it is of a strikingly handsome appearance in autumn from its copious crimson, smooth, four-lobed capsules, which are pendulous on long peduncles. Its branches are slightly quadrangular; the leaves opposite, petioled, elliptic-ovate, serrate, and pointed; the flowers are dark purple, in loose cymes of three to six, and appear in June. The root-bark is preferred.

Description.—It comes in curved or quilled fragments varying in thickness between $\frac{1}{16}$ and $\frac{1}{8}$ inch. It is externally of a light ash-gray color, mottled with larger or smaller patches of dark brown or blackish; the corky layer is detached in very thin and small scales. The inner surface, to which fragments of the white wood are often adhering, is brownish-white and smooth. When dry the bark breaks, both transversely and longitudinally, with a nearly smooth fracture, exhibiting a whitish tissue which in the inner layers has a distinct tangential arrangement. The bark attracts moisture in a damp atmosphere, thereby losing its brittleness, is nearly inodorous, and has a sweetish, afterwards bitterish, and somewhat acrid taste.

Constituents.—W. P. Clothier (1861) isolated bitter, yellow, acicular crystals from the tincture prepared with diluted alcohol by agitating it with chloroform. The same principle is probably contained in the so-called *euonymin* of the eclectics, which is obtained by precipitating a concentrated tincture of the bark with water. W. T. Wenzell (1862), however, obtained by treatment of the tincture with chloroform a dark-yellow substance, from which ether dissolved a golden-yellow resin; the insoluble portion was dissolved by alcohol, a resin precipitated by acetate of lead, and the lead removed from the filtrate; on evaporation uncrystallizable *euonymin* was left having an intensely bitter taste. It is a neutral principle soluble in ether (?), alcohol, and water, and precipitated by subacetate of lead and phosphomolybdic acid. Wenzell obtained also *asparagin*, *euonic acid*, which crystallizes in needles and is precipitated by subacetate of lead; tartaric, malic, and citric acids; several resins, starch, pectin, and other common vegetable principles. The dried bark left 14.75 per cent. of ash, about half of which consisted of silica.

Allied Drugs.—EUONYMUS AMERICANUS, *Lin.*, *strawberry bush*, is a low, usually trailing shrub, with crimson warty capsules and orange-red roots.

EUON. EUROPÆUS, *Lin.*, is 8 to 20 feet high, occasionally cultivated in gardens, has greenish-yellow flowers, and pale-red capsules, the arillus being orange-red. All parts of it are emetic and purgative; the fruit made into an ointment has been used for the destruction of pediculi. Riederer (1833) believed the bitter taste to be due to an alkaloid, *euonymin*, which he did not succeed in obtaining pure. Grundner (1847) regarded it as a mixture of resin with bitter extractive. The arillus yields by pressure an orange-colored oil which has a bitter taste. The orange-red coloring matter, which is quite prevalent in this natural order, seems to deserve careful investigation.

Medical Action and Uses.—Wahoo is reported, but not upon sufficient authority, to be a "tonic, hydragogue cathartic, diuretic, and antiperiodic." Certain physicians practising in malarial localities are apt to see a cholagogue in every purgative, and this one is no exception to the rule. A decoction or an infusion, made with an ounce of the bark to a pint of water, may be given in the *dose* of a wineglassful.

EUPHRASIA.—EYEBRIGHT.

Euphraise, Fr.; *Augentrost*, G.

Euphrasia officinalis, *Lin.* *Nat. Ord.*—Scrophulariaceæ.

Description.—An annual plant about 6 inches high, indigenous to the greater part of Europe, and in North America to the White Mountains and from the great lakes northward. It has opposite, shortly-petiolate, ovate, or lanceolate leaves, which are about one-third inch long, and have four or five teeth on each side; the upper (floral) leaves are alternate, nearly rhomboid, and bristly-toothed. The axillary flowers have a four-cleft calyx and a white or lilac two-lipped corolla with a yellow throat, four ascending stamens, and an oblong, many-ovuled ovary. When fresh the plant has a faint balsamic odor, which is almost completely lost on drying; the taste is somewhat saline, bitter, and scarcely astringent.

Constituents.—Examined by J. B. Enz (1859), the fresh plant was found to contain 62 per cent. of moisture and 10.8 per cent. of cellulose, the remainder being tannin, a little volatile oil, an acrid and bitter principle, several organic acids, mannite, glucose, and other common principles. The tannin precipitates ferric salts dark green, and lead salts of a bright green color.

Medical Action and Uses.—The name euphrasia, signifying cheerfulness, was anciently as well as in more recent times given to this plant, which was supposed to render the vision clearer, and to cure various inflammatory affections of the eyes. Its English name *eyebright* may be due to this circumstance; but some maintain that its use in such disorders was prompted by the doctrine of signatures, for a yellow spot upon its flower suggests the pupil of the eye. Its utility, when applied as a fomentation or decoction in *ophthalmia*, was probably due to its astringency. A vinous decoction of it was esteemed in *toothache;* a closely allied species also used for this affection was for that reason called *odontitis*. Internally, eyebright was also given, as a distilled water or a tincture, for *chronic catarrhs*.

EXTRACTA.—EXTRACTS.

Extraits, Fr.; *Extrakte*, G.

Extracts are preparations which are obtained by removing from crude drugs a solution of their medicinal principles, and evaporating it to the consistence of a soft solid or to dryness. The medicinal principles may be removed either by expressing the crude drugs while fresh and juicy, or by exhausting the dried and powdered drugs with water, alcohol and water, alcohol, or ether, whereby the *inspissated juices* or the *aqueous*, *hydro-alcoholic*, *alcoholic*, or *ethereal extracts* are obtained; the latter contain all the fixed and volatile oils, together with the resin, which may have been contained in the drug, and usually remain liquid after the solvent has been completely evaporated, for which reason the Pharmacopœia has separated them as *oleoresinæ* (which see).

INSPISSATED JUICES.—The United States Pharmacopœia has admitted four inspissated juices, which, however, with the exception of one (Ext. taraxaci), can be prepared by the pharmacist in exceptional cases only, because the plants are not indigenous or grow spontaneously only in a few localities; they might very properly be dismissed or replaced by aqueous extracts which may be prepared by the pharmacist. The expressed juices of herbaceous plants contain, besides the medicinal principles, chlorophyll in suspension and albuminous and mucilaginous matters in solution. Of these, the chlorophyll separates on heating the liquid to about 55° C. (130° F.); the albumen is not coagulated until the temperature reaches about 94° C. (200° F.), and the solubility of the gum and mucilage is not affected by heat; but these principles may be removed by alcohol, in which they are insoluble. The different Pharmacopœias have adopted different processes for the purification of the expressed juices; that of Germany endeavors to obtain the extracts as free as possible from inert principles, and purifies by heat and by alcohol; those of France and the United States direct the juice to be coagulated by heat, but the gum is not precipitated; and that of Great Britain aims only at the separation of the albumen, and reincorporates with the extract the previously removed chlorophyll. The inspissated juices of the latter are of a green color and of a firm pilular consistence; those of the other Pharmacopœias are brown in color, and cannot be made into pills without the addition of some vegetable powder. Provided the material has been of the same quality, an inspissated juice made according to the German Pharmacopœia ought to be stronger, and if made by the British Pharmacopœia weaker, than is obtainable by the United States process.

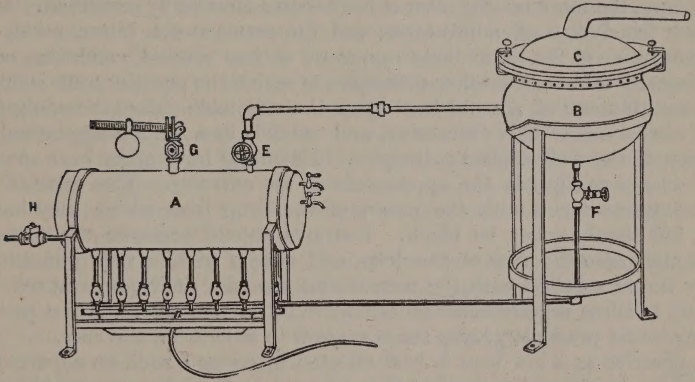
To obtain the juice, the vegetable should have been recently collected, well washed with water to free it from extraneous matter, and the superfluous water drained off. It is then cut into pieces of convenient size, and bruised in a stone mortar by means of a pestle made of hard wood until reduced to a smooth pulpy mass. If not succulent enough, a little water may be sprinkled over it during this operation. The mass is then inclosed in canvas bags, strongly expressed, again mixed with water, and expressed a second time, whereby that portion of the juice remaining in the pulp is obtained. The mixed liquids are then heated to the boiling point (to 80° C.=176° F., P. G.) to coagulate the albumen, which incloses also the chlorophyll, and is removed by straining, after which the clear liquid is evaporated to the proper consistence. The German Pharmacopœia directs the strained liquor to be evaporated until reduced in weight to 10 per cent. of the weight of the plant, when an equal weight of alcohol is added to precipitate gummy matter; the mixture is set aside until the insoluble matter has subsided, it is then strained, and the retained liquid obtained by the addition of a little diluted alcohol; the alcohol is partly distilled off, and the remaining liquor evaporated as before. The British Pharmacopœia directs the heating of the expressed juice to 130° F., whereby the chlorophyll separates from the liquid, and is collected upon a calico strainer. The strained liquor is now heated to 200° F. to coagulate the albumen, again strained, and evaporated to the consistence of a thin syrup, to which the chlorophyll, previously separated, is added, and well mixed by assiduous stirring. Evaporation to the proper consistence will complete the extract. If the part of the plant employed does not contain chlorophyll, its removal and subsequent readmixture are obviously omitted from the process, and, if starch is present, some of it will pass through the press-cloth, and the expressed juice must be allowed to subside and then be decanted from the deposited fecula.

Aqueous Extracts were formerly usually made by boiling the drug with water, expressing the watery solution, and evaporating. The Pharmacopœias have very properly discontinued this process almost altogether, and have in nearly all cases substituted infusion or percolation with water. Prolonged boiling with water will often render inert constituents (starch, etc.) soluble in water, and thus increase the amount of extract to the injury of its quality. In other cases, however, it may not only injure the quality, but also decrease the yield of the extract, as in the case of krameria, the tannin of which is either partly destroyed or becomes insoluble through combination with other constituents. Some Pharmacopœias exhaust the comminuted drugs by hot infusion or digestion; but cold infusion or percolation appears to produce not only unobjectionable aqueous extracts, but they are in some cases at least superior in appearance to those made by hot infusion or digestion. When infusion is directed, the properly comminuted drug is mixed with sufficient water to cover it, and, in case the material be light, it is submerged by putting a perforated cover with sufficient weights upon it to keep it covered by the water. After due maceration or digestion, a concentrated solution of the principles is at once obtained by expression, and a second maceration and expression will practically exhaust the drug. If a large quantity of water be used in the beginning, a second maceration may be avoided or becomes unprofitable, but a longer continued evaporation is necessary.

For the proper treatment of the material by percolating with water we refer to the remarks on Percolation (see Extracta fluida).

Alcoholic Extracts.—Whether made with strong or diluted alcohol, the powdered material is most conveniently exhausted by percolation, which process is fully described under the head of Extracta fluida. For some extracts, alcohol and diluted alcohol are used; in such cases the former is always used first, and, by the addition of the latter, an amount of percolate obtained equal to that of the alcohol employed, and kept separate from the percolate with the weaker alcohol. The two liquids are separately distilled and evaporated to the consistence of syrup, then mixed while warm, and the mixture well stirred and evaporated to the proper consistence. The stronger alcoholic solution requires sometimes to be evaporated at a low temperature, and spontaneous evaporation in a warm place is then usually directed. The alcohol which is lost in this operation may be recovered by using a shallow pharmaceutical still, which may be placed in a water-bath, and the head of which is provided on the inside with a gutter; the tincture to be concentrated is put into a porcelain evaporating dish; this is placed in the still and the moderate heat of a water-bath applied, when the alcohol will slowly evaporate, condense upon the inside of the cooled head, collect in the gutter below, and be discharged through the neck. Besides recovering the alcohol, this arrangement has also the advantage of keeping the liquid free from dust and other accidental impurities. For uses on a small scale, Prof. Parrish has somewhat modified the steam evaporating pan and still, and constructed an apparatus which is shown in the annexed cut. *A* is a boiler made of thick copper, which may be heated either by a furnace or by several Bunsen burners. Water is supplied through the valve *H*; *G* is a safety valve; *E* is the valve for regulating the supply of steam, which is carried off through the exhaust valve *F*. The evaporating pan, made of well-tinned copper, is coupled together with the steam-jacket *B*, upon the flanges of which is fitted the head *C*, and secured by means of clamps, the joint being made steam-tight by placing a coil of lamp-wick or loose cord between the flanges. If used for distillation, *C* is connected with a condenser; if for evaporation only, *C* is removed. By proper regulation at *E* and *F*, either a very moderate heat may be applied to the pan or the temperature may be raised above the boiling point of water.

Fig. 65.



Steam-boiler with Still.

Hydro-alcoholic Extracts, in the preparation of which both alcohol and water are used, are now almost obsolete, and the one still officinal in the United States Pharmacopœia should be discontinued in its present form. The operation is similar to that of making alcoholic extracts by using alcohol of different strengths;

the alcoholic and aqueous solutions are evaporated separately to a syrupy consistence, then well mixed, and evaporated to the proper consistence.

Ethereal Extracts.—All the ethereal extracts of the United States Pharmacopœia will be found under *Oleoresinæ*, where also the necessary apparatuses and operations are described. Ext. mezerei æthereum, *Br. Ph.*, is the ethereal extract of an alcoholic extract, the latter being prepared from the drug and afterwards exhausted by ether.

Evaporation of the Solutions.—This is an important operation in the preparation of extracts for which the Pharmacopœia gives, besides some special directions, the general one "to evaporate as quickly as possible in a broad shallow vessel, by means of a water-bath, and, towards the end of the process, to stir constantly with a spatula." All plants contain one or more principles which, though originally colorless, are very easily altered under the influence of air and heat, acquiring a yellow or brown color. It is not known whether the so-called *colorless extractive* is alike in all plants; nor is its composition known or the nature of changes produced under the conditions mentioned, except that the heat of boiling water and the prolonged action of oxygen will convert it ultimately into a blackened insoluble substance, to which the name *apotheme* has been given, and which appears to be allied to *humin*. Extractive is almost insoluble in absolute alcohol and ether, but dissolves freely in weaker alcohol and water, and is removed from its solutions by animal charcoal and hydrate of aluminium, the more readily after it has become colored by oxidation. It is with difficulty freed from all admixtures, and the terms sweet, bitter, acrid, etc. extractives refer to the same body in a more or less altered condition, combined or intimately mixed with other principles to which the peculiar taste is due. The injurious influence of air and heat upon the vegetable juices is mainly confined to the alterations of this extractive, and extends in a limited degree only to the majority of the well-defined principles. Its effects have often been much overrated, except as regards the appearance of the extracts. The color of the different extracts varies with the nature of the drug from which they have been made, but should never be black. Extracts should preserve the taste, and to some extent also the odor of the drug, and should yield a nearly clear or moderately turbid solution with the menstruum used in their preparation. Not to come up to these requirements is indicative of carelessness, and the presence of empyreumatic products proves the operation to have been slovenly.

Evaporation at a low heat is best effected *in vacuo;* such an apparatus, however, is too costly and complicated to be used in the laboratory of the pharmacist. The use of a water-bath is well adapted for preserving a low temperature, and if a shallow dish is used and a current of air conducted over the surface of the liquid, rapid evaporation will be effected and all danger of injuring the product avoided.

Fig. 66.

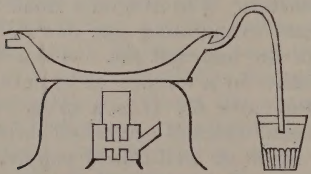


Fig. 67.

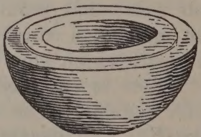


Water-baths.

The vessels used for this part of the process are of great importance for the quality of the extract. Metallic vessels should, as a general rule, be avoided, since the tannin and free acids or acidulous salts contained in many drugs would, by the prolonged necessary contact, contaminate the extract with iron or copper.

Tin is less liable to be thus attacked, and is therefore, in most cases, unobjectionable. The most suitable vessels for the purpose are porcelain dishes or well-enameled iron pans, with a rounded bottom, which may also be used for recovering the alcohol at a low heat, in the manner described above.

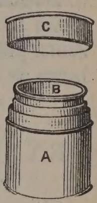
For the reasons stated, the use of metallic spatulas for stirring the extracts during evaporation is generally inadmissible: the proper material is porcelain or wood. Various mechanical contrivances have been constructed with the view of saving the manual labor and constant attendance in stirring, and they serve a good purpose.

Consistence of Extracts.—The Pharmacopœia recognizes two degrees of consistence, namely, dry and powdered, and a consistence proper for forming pills. The latter is practically unattainable in the majority of cases, unless some dry substance is added, like the chlorophyll, to the inspissated juices of the British Pharmacopœia. The nearest degree of consistence attainable with some extracts is such that they may be formed into pills, which, however, do not retain their globular shape. Others, like Extr. gentianæ, taraxaci, etc., are even too soft for that purpose, while some, like Extr. jalapæ, rhei, etc., gradually become quite tough or hard. Extracts which do not contain any fixed oil or hygroscopic constituents, may be evaporated and, after cooling, reduced to powder. On being warmed, all extracts become softer, and, if pulverulent at the ordinary temperature, acquire sufficient pliability to be rolled into pills.

Preservation.—The consistence of extracts nearly neutralizes any injurious effect which contact with the atmosphere might otherwise exert, and the most ordinary care will therefore suffice to keep them unaltered for a considerable time. The Pharmacopœia directs the sprinkling upon the softer extracts of a small quantity of alcohol; but this is entirely unnecessary for those which are to some degree hygroscopic, and of little permanent utility for those which have a tendency to become tough. The difficulty may generally be avoided, by spreading a few drops of glycerin over the surface, or, as has been proposed, by working into the warm extract half its weight of glycerin and dispensing fifty per cent. more than prescribed.

The ordinary extracts are kept in jars of queensware, or, preferably, of porcelain, with a cover of the same material. Small quantities may be kept in wide-mouthed vials, with a very narrow shoulder, or in an ordinary tie-over jar, inclosed in a tin box, just large enough to receive it, and provided with a well-fitting cover.

Fig. 68.



Jar in Tin Box.

Powdered extracts, if not hygroscopic, are kept in a jar or bottle. For convenience in dispensing, the German Pharmacopœia directs the reduction of a portion of the different narcotic extracts to powder by warming the extract in a porcelain dish, incorporating an equal weight of dextrin, drying the mixture at a temperature of 40° to 50° C. (104° to 122° F.), rubbing it to powder, and adding sufficient dextrin to make the weight of the powder double that of the extract employed. 2 grains of this powder represent 1 grain of the extract.

Yield and Composition.—Considering the variable condition of the drugs, as influenced by climate, soil, time of collection, etc., the yield cannot be uniform, even if the same process be scrupulously followed. Recently dried herbs usually yield more extract than the same herb in the fresh state, or kept on hand for some months. For similar reasons, the composition of the extracts must vary as much as the drugs from which they are prepared. Certain extracts, when kept on hand for some time, form throughout their mass acicular crystals of potassium nitrate, the acid being probably formed through the gradual oxidation of some nitrogenized, probably albuminous principle.

EXTRACTUM ACONITI, *U. S.*, *Br.*—EXTRACT OF ACONITE.

Extractum foliorum (vel herbæ) aconiti.—Extract of aconite leaves, E.; *Extrait de feuilles d'aconit*, Fr.; *Eisenhutblätter-Extrakt*, G.

Preparation.—Take of Aconite Leaves recently dried and in fine powder twelve troyounces; Alcohol a pint; Diluted Alcohol a sufficient quantity. Introduce the powder, previously mixed with one-third of the alcohol, into a conical percolator, and pour upon it the remainder of the alcohol. When the liquid has all been absorbed by the powder, pour on diluted alcohol until a pint of tincture has been obtained. Set this aside in a warm place, and allow it to evaporate spontaneously until reduced to three fluidounces. Continue the percolation with diluted alcohol until two pints more of tincture have passed, or until the powder is exhausted; then evaporate, by means of a water-bath, at a temperature not exceeding 160° F., to the consistence of syrup, and add the three fluidounces of tincture first obtained. Lastly, continue the evaporation at a temperature not exceeding 120° F., until the whole is reduced to the proper consistence. *U. S.*

Take of the Fresh Leaves and Flowering Tops of Aconite one hundred and twelve pounds. Bruise in a stone mortar and press out the juice; heat it gradually to 130° F. and separate the green coloring matter by a calico filter. Heat the strained liquor to 200° F. to coagulate the albumen, and again filter. Evaporate the filtrate by a water-bath to the consistence of a thin syrup; then add to it the green coloring matter previously separated, and, stirring the whole together assiduously, continue the evaporation at a temperature not exceeding 140° F. until the extract is of a suitable consistence for forming pills. *Br.*

The two processes yield brown-green extracts, which are probably of very nearly the same strength; the first contains the chlorophyll and resinous matter of the leaves to the exclusion of the gummy constituents which are present in the latter. It should be remembered that the *Extr. aconiti* of the German Pharmacopœia is prepared from aconite root by exhausting it with alcohol, specific gravity .892, and is about 6 to 8 times stronger than the extract prepared from the herb.

Medical Uses.—This extract may be given in the dose of from half a grain to a grain, gradually increased if necessary. An alcoholic extract of the root, prepared in the same manner, may be prescribed in doses one-third as large as those just indicated.

EXTRACTUM ALOES BARBADENSIS, *Br.*—EXTRACT OF BARBADOES ALOES.

Extrait d'aloès de Barbades, Fr.; *Barbadoes Aloe-Extrakt*, G.

Preparation.—Take of Barbadoes Aloes in small fragments one pound; Boiling Distilled Water one gallon. Add the aloes to the water, and stir well until they are thoroughly mixed. Set aside for twelve hours, then pour off the clear liquor, strain the remainder, and evaporate the mixed liquors by a water-bath or a current of warm air to dryness. *Br.*

Medical Uses.—There does not appear to be any advantage in this extract over aloes itself. Its *dose* is the same, or from two to six grains.

EXTRACTUM ALOES SOCOTRINÆ, *Br.*—EXTRACT OF SOCOTRINE ALOES.

Extrait d'aloès sucotrin, Fr.; *Socotora Aloe-Extrakt*, G.

Preparation.—Take of Socotrine Aloes in small fragments one pound; Boiling Distilled Water one gallon. Add the aloes to the water, and stir well until they are thoroughly mixed. Set aside for twelve hours; then pour off the clear liquor, strain the remainder, and evaporate the mixed liquors by a water-bath or a current of warm air to dryness. *Br.*

The two extracts of aloes are yellowish-brown powders, which yield turbid solutions with water. The introduction of *purified aloes* into the U. S. Pharmacopœia renders an extract scarcely necessary. The extract of the German Pharmacopœia is made by maceration with *cold* water; the latter recognizes also an *Extractum aloes acido sulphurico correctum*, which is obtained by diffusing 8 parts of the extract in 32 parts of distilled water, adding gradually 1 part of sulphuric acid, and evaporating to dryness.

Medical Uses.—It may be given for the same purposes as the extract of Barbadoes aloes, or as aloes itself, and in the same *dose*, from two to six grains.

EXTRACTUM ANTHEMIDIS, *Br.*—EXTRACT OF CHAMOMILE.

Extractum chamomillæ Romanæ.—*Extrait de camomille romaine*, Fr.; *Römisch-Kamillen-Extrakt*, G.

Preparation.—Take of Chamomile Flowers one pound; Oil of Chamomile fifteen minims; Distilled Water one gallon. Boil the chamomile with the water until the volume is reduced to one-half, then strain, press, and filter. Evaporate the liquor by a water-bath until the extract is of a suitable consistence for forming pills, adding the oil of chamomile at the end of the process. *Br.*

It is a dark-brown extract, having the odor and bitter taste of chamomile. It would seem not to be very difficult to work out a better process, in which the long boiling should be avoided.

Medical Uses.—It is, like extract of gentian, a convenient excipient for tonic medicines given in the pilular form, especially quinia and the salts of iron. It is by itself a mild stomachic tonic. *Dose*, from two to ten grains.

EXTRACTUM ARNICÆ, *U. S.*—EXTRACT OF ARNICA.

Extractum arnicæ alcoholicum.—*Extrait d'arnique*, Fr.; *Arnika-Extrakt*, *Wohlverleih-Extrakt*, G.

Preparation.—Take of Arnica in moderately coarse powder twenty-four troyounces; Alcohol four pints; Water two pints; Diluted Alcohol a sufficient quantity. Mix the alcohol and water, and moisten the powder with a pint of the mixture; then pack it firmly in a cylindrical percolator, and gradually pour on the remainder of the mixture. Continue the percolation with diluted alcohol until six pints of tincture have passed. Lastly, evaporate, by means of a water-bath, to the proper consistence. *U. S.*

The yield is about 30 per cent. of the weight of the flowers. The extract is of a brown color, slight odor, and bitter and acrid taste.

Medical Uses.—It is seldom, if ever, prescribed internally, although its *dose* is stated to be from five to ten grains. Its chief use is in making arnica plaster.

EXTRACTUM BELLADONNÆ, *U. S.*, *Br.*—EXTRACT OF BELLADONNA.

Extrait de belladone, Fr.; *Tollkirschen-Extrakt*, G.

Preparation.—Take of Belladonna Leaves, fresh, twelve troyounces. Bruise the leaves in a stone mortar, sprinkling on them a little water, and express the juice; then, having heated this to the boiling point, strain, and evaporate to the proper consistence. *U. S.*

Take of the fresh Leaves and young Branches of Belladonna one hundred and twelve pounds. Bruise in a stone mortar, and press out the juice; heat it gradually to 130° F., and separate the green coloring matter by a calico filter. Heat the strained liquor to 200° F., to coagulate the albumen, and again filter. Evaporate the filtrate by a water-bath to the consistence of a thin syrup; then add to it the green coloring matter previously separated, and, stirring the whole together assiduously, continue the evaporation at a temperature not exceeding 140° F., until the extract is of a suitable consistence for forming pills. *Br.*

The first formula yields a brown, and the second a greenish-brown extract; the yield of the former is about $3\frac{1}{2}$ per cent.

Medical Uses.—A number of local applications of this, as of all other narcotic extracts, exists. Softened with water, or mixed with oil, it enters into many magistral formulæ for the relief of local pains, especially those of a *neuralgic* sort. A more elegant form for this purpose is belladonna plaster. Its relaxing and anodyne operations combined are used in spasm of muscles surrounding canals, as the *ureter*, *bladder*, *urethra*, *os uteri*, *vagina*, and *rectum*, when irritation excites their contraction. In these several cases the extract softened may be rubbed in as near as possible to the seat of pain; or it may be introduced in a suppository into the vagina or rectum. When applied to the prepuce in phimosis and in paraphimosis, it sometimes reduces the engorgement and stricture. Rubbed on the forehead or eyelids it was formerly much used to *dilate the pupil;* but the more cleanly solution of atropia is to be preferred. It may be used internally for all the purposes to which belladonna is appropriate. Extract of belladonna is of uncertain strength, and its dose is therefore variable. A quarter of a grain may be given three times a day, and the quantity gradually increased, until the state of the pupil denotes the degree of its action.

EXTRACTUM BELLADONNÆ ALCOHOLICUM, *U. S.*—ALCOHOLIC EXTRACT OF BELLADONNA.

Extrait de belladone alcoholique, Fr.; *Spirituöses Tollkirschen-Extrakt*, G.

Preparation.—Take of Belladonna Leaves in fine powder twenty-four troyounces; Alcohol four pints; Water two pints; Diluted Alcohol a sufficient quantity. Mix the alcohol and water, and moisten the powder with a pint of the mixture; then pack it firmly in a conical percolator, and gradually pour upon it the remainder of the mixture. Continue the percolation with diluted alcohol until six pints of tincture have passed. Lastly, evaporate, by means of a water-bath, to the proper consistence. *U. S.*

The yield is about 22 per cent. of greenish-brown extract having the bitter taste of belladonna.

Medical Uses.—The uses and the dose of this preparation are essentially the same as those of the simple extract of belladonna.

EXTRACTUM CALUMBÆ, *Br.*—EXTRACT OF CALUMBA.

Extractum colombo, P. G.—*Extrait de colombo*, Fr.; *Kolombo-Extrakt*, G.

Preparation.—Take of Calumba Root, cut small, one pound; Distilled Water four pints. Macerate the calumba with two pints of the water for twelve hours, strain and press. Macerate again with the same quantity of water, strain and press as before. Mix and filter the liquors, and evaporate them by the heat of a water-bath until the extract is of a suitable consistence for forming pills. *Br.*

The yellowish-brown extract contains the mucilaginous and bitter principles of calumba.

Medical Uses.—This preparation, which in its action differs but little from the extracts of colombo and gentian, may be prescribed in the *dose* of from two to ten grains.

EXTRACTUM CANNABIS AMERICANÆ, *U. S.*—
EXTRACT OF AMERICAN HEMP.

Extrait de chanvre américain, Fr.; *Amerikanischer Hanf-Extrakt*, G.

Preparation.—Take of American Hemp in moderately fine powder twelve troyounces; Alcohol a sufficient quantity. Moisten the hemp with six fluidounces of alcohol, pack it in a conical percolator, cover the surface with a disk of paper, and pour on six fluidounces of alcohol. When the liquid begins to drop from the percolator, close the lower orifice with a cork, and, having closely covered the percolator to prevent evaporation, set it aside in a moderately warm place for four days. Then, having removed the cork, gradually pour alcohol upon the surface until two pints of tincture have been obtained, or until the hemp is exhausted. Lastly, by means of a water-bath, evaporate to the proper consistence. *U. S.*

Medical Uses.—The *dose* of this extract is as variable as that of Indian hemp, and it should be administered with the same precautions.

EXTRACTUM CANNABIS INDICÆ, *U. S.*, *Br.*—EXTRACT OF INDIAN HEMP.

Extrait de chanvre indien, Fr.; *Indischer Hanf-Extrakt*, G.

Preparation.—Take of Indian Hemp in moderately fine powder twelve troyounces; Alcohol a sufficient quantity. Moisten the hemp with six fluidounces of alcohol, pack it in a conical percolator, cover the surface with a disk of paper, and pour on six fluidounces of alcohol. When the liquid begins to drop from the percolator, close the lower orifice with a cork, and, having closely covered the percolator, to prevent evaporation, set it aside in a moderately warm place for four days. Then, having removed the cork, gradually pour alcohol upon the surface until two pints of tincture have been obtained, or until the hemp is exhausted. Lastly, by means of a water-bath, evaporate to the proper consistence. *U. S.*

Take of Indian Hemp in coarse powder one pound; Rectified Spirit four pints. Macerate the hemp in the spirit for seven days, and press out the tincture. Distil off the greater part of the spirit, and evaporate what remains by a water-bath to the consistence of a soft extract. *Br.*

The extract is of a blackish-green color, having a slight but heavy narcotic odor and a bitter taste. Nitric acid converts it into an orange-red resin, which after washing with water has the color of gamboge. (Procter, 1864.)

Medical Action and Uses.—This extract varies so greatly in activity that its dose cannot be definitely fixed. Half a grain of a specimen not before tested should be given at first, and gradually the dose should be increased until its sensible effects are produced.

EXTRACTUM CARNIS, *P. G.*—EXTRACT OF MEAT.

Extractum carnis Liebig.—Extrait de viande de Liebig, Fr.; *Liebig's Fleischextract*, G.

Preparation.—In 1854 Liebig published a formula for preparing a *broth for invalids* as follows: Half a pound of fresh meat is finely chopped and macerated for one hour with one pound of cold distilled water, to which four drops of hydrochloric acid and from thirty to sixty grains of table-salt are added. The mass is then displaced on a colander, a little water being added, until one pound of percolate has been obtained. The clear liquid has a red color, and contains the albuminoids of the meat in solution. In 1859 the Bavarian Pharmacopœia adopted a process for extract of meat, in which chopped meat was exhausted with hot water, and the expressed liquid, carefully freed from fat and albumen, was evaporated.

Since then factories have been established in different parts of South America, Australia, and the United States, where cattle are abundant and cheap. In the majority of these establishments Liebig's process appears to be followed, perhaps with some slight modification. At Fray-Bentos, on the river Uruguay, where a factory was conducted under the direction of Liebig, the extract, according to F. Müller (1868), is prepared as follows: The freshly slaughtered meat is allowed to cool for twenty-four hours, and then ground into a pulpy mass by passing it between iron rollers furnished with small projections. The pulp is stirred with water for about an hour, strained through sieves, the fat carefully removed, and the liquid evaporated in steam-pans, a current of air being continuously passed over the surface. At a certain state of concentration the liquid is filtered, and the evaporation continued until the extract is transferred to well glazed stoneware jars which are carefully covered.

Properties.—Thus prepared, extract of meat is of a brown color, and has a pleasant odor suggestive of roasted meat. It is completely soluble in water, yielding a clear solution, which, on the addition of a little table-salt, has the flavor of beef-broth. When dried at the temperature of 110° C. (230° F.), 100 parts of the extract should lose not over 22 parts of moisture, and after incineration not less than 18 parts of ashes should be left, containing only a small quantity of sodium chloride. If 100 parts of the extract are digested with alcohol, and the liquid filtered and evaporated, not less than 56 parts of extract should be obtained. (P. G.) The figures given by Liebig himself as indicating the limits of variation in extract of meat prepared by his process are for *moisture* 16 to 22 per cent.; *ash* 18 to 22 per cent.; *extractive*, soluble in 80 per cent. alcohol, 56 to 66 per cent. The absence of chloride of sodium in meat-juice is proven by precipitating first the salts of inosic acid by an equal bulk of alcohol, and then adding five volumes of alcohol, when the mixture will separate into two layers, the lower of which, about one-twentieth of the whole, on evaporation at a low temperature will yield prisms of the chloride of potassium, containing not a trace of sodium salt.

The amount of nitrogen in extract of meat is sometimes as low as 4 per cent.; but if made of good beef usually between 9 and 10 per cent., and depends chiefly on the presence of *creatin*, *creatinin*, *globulin*, and *urea*. The solution in water of the extract usually yields a slight precipitate with tannin, which, according to Eichhorn (1867), is due to the presence of a nitrogenated body, which somewhat resembles gelatin, but is not identical with it. Werner (1868), however, states that, if in preparing the extract the temperature of 60° C. (140° F.) be not exceeded, the aqueous solution will give no reaction for gelatin. It would seem, therefore, best to evaporate the liquid under reduced pressure. It is well known, however, that some extracts of meat which have appeared in our market have contained large quantities of gelatin. (See paper by A. E. Ebert in *Proc. Amer. Pharm. Association*, 1871, p. 512.)

Other extracts of meat, liquid as well as solid, have from time to time claimed attention. In 1873 Prof. Leube recommended an extract, in which the meat fibrin is also utilized by being emulsionized. Mirus recommends its preparation by the following process: 250 grams of meat, free from fat and bones, and chopped fine, are introduced into a strong bottle and agitated with 250 grams of water containing 2 per cent. of muriatic acid, until all lumps have disappeared, when the bottle is corked and the stopper wired. Five or six of such bottles are boiled in a high pot for fifteen hours; each bottle is then well agitated, and the boiling continued for fifteen hours more. The preparation may also be made in a suitable steam boiler by placing the meat in a covered porcelain vessel, and boiling for the length of time indicated. The object is to alter the muscular fibres under pressure and under the conditions stated, until they are as nearly disintegrated as possible. In the liquid state the preparation soon spoils, unless preserved by Appert's method; it may, however, be evaporated in a steam-bath to dryness, when it will keep well in closed bottles, and should, when prescribed, be softened by the addition of warm water.

Physiological Action and Medical Uses.—It appears to be too often overlooked that Liebig, to whom is due the vogue of beef-tea during the last quarter of a century, expressly declared it to be incapable of promoting nutrition, and that it is to be classed as nervous food along with tea, coffee, and alcohol, and even as inferior to the last. The very small proportion of two and a half per cent. of albumen which it contains, according to some modes of preparation, is altogether eliminated in Liebig's extract, and the gelatin almost completely, leaving the organic alkaloids and acids and the salts. That these act as temporary nervous stimulants there can be no doubt; but the popular impression is that beef-tea is a substitute for food, and hence it often happens that the patient is plied with it inordinately, with the result of provoking vomiting or diarrhœa. That it often occasions the latter when habitually used as a substitute for food, to repair fatigue, or to fortify the body or mind for an unusual exertion, is probably within the experience of many physicians. It is, however, rather indirectly than directly injurious by being used as a nutrient, a function which it has no claim to perform. On the other hand, it has not that poisonous operation which science, falsely so called, attributed to it through Kemmerich in 1868. He arrived at the singular conclusion that concentrated cold extract of horse-flesh injected into the stomach of dogs, in small doses, increases the number and strength of the heart's pulsations, but that in large doses it kills, with all the appearances of cardiac paralysis. This remarkable result he attributes to the potash salts of the meat!

The stimulant and non-nutritious qualities of beef-tea render it peculiarly fitted for the treatment of the greater number of acute *febrile diseases*. Nature protests against the use of food in them, by the repugnance of the patients to taking it, and by the aggravation of the fever which it induces. During the augment and acme of these affections, food in a literal sense heaps fuel on the fire; but in many of them the animal mechanism must be kept in such active movement as to enable it to resist the disintegrating tendencies of the disease, and afterwards to throw off the effete accumulations. This, beef-tea aids in accomplishing, in the same manner as alcohol. When that end is attained, and when the fever has declined, the preparation holds only a secondary place in the treatment, the first being occupied by true nutrients, which are better prepared by culinary skill than by chemical science. Feeding by the rectum with beef-tea is, if possible, of even more temporary utility than when this preparation is given by the stomach. Pancreatic emulsion is more efficient. It is highly recommended in various affections of the stomach when the mucous coating requires to be protected from irritation in convalescence from typhus, etc., and may be combined with broth or with Liebig's extract of meat; or milk and powdered cracker may be used alternately with it. It has been employed with marked advantage in cases of *fatty diarrhœa* due to obstruction of the pancreatic secretion, and in the *wasting diseases* of children induced by artificial feeding. It also promotes the digestion and assimilation of *cod-liver oil.*

EXTRACTUM CINCHONÆ, *U. S.*—EXTRACT OF CINCHONA.

Extractum Chinæ.—Extract of calisaya bark, E.; *Extrait de quinquina jaune*, Fr.; *China-Extrakt*, G.

Preparation.—Take of Yellow Cinchona in fine powder twelve troyounces; Alcohol three pints; Water a sufficient quantity. Mix the powder with twenty fluidounces of the alcohol, and allow the mixture to stand for four days; then introduce it into a conical glass percolator, and gradually pour upon it the remainder of the alcohol. When the liquid ceases to pass, pour upon the residue sufficient water to keep its surface covered, until three pints of tincture have passed. Set this portion aside, and continue the percolation until six pints of infusion are obtained. Distil off the alcohol from the tincture, and evaporate the infusion until the liquids respectively are brought to the consistence of thin honey; then mix them, and, by means of a water-bath, evaporate to the proper consistence. *U. S.*

If the percolation has been properly conducted, there appears to be little necessity of obtaining such a large amount of aqueous infusion after the bark has been exhausted by alcohol. The extract is of a reddish-brown color, has the persistently bitter taste of cinchona, and, on keeping, becomes dry. The German Pharmacopœia recognizes an *Extractum Chinæ frigide paratum*, which is obtained by evaporating the cold aqueous infusion of pale cinchona bark.

Medical Uses.—Extract of cinchona, since it possesses all the virtues of Peruvian bark, would for many purposes be preferable to quinia, were it less bulky. The *dose* is from ten to thirty grains.

EXTRACTUM COLCHICI, *Br.*—EXTRACT OF COLCHICUM.

Extrait de colchique, Fr.; *Zeitlosen-Extrakt*, G.

Preparation.—Take of Fresh Colchicum Corms deprived of their coats seven pounds. Crush the corms, press out the juice; allow the feculence to subside, and heat the clear liquor to 212° F.; then strain through flannel, and evaporate by a water-bath at a temperature not exceeding 160° F., until the extract is of a suitable consistence for forming pills. *Br.*

This is a brown extract, having a bitter taste, and yielding with water a rather turbid solution.

EXTRACTUM COLCHICI ACETICUM, *U. S.*, *Br.*—ACETIC EXTRACT OF COLCHICUM.

Extrait de colchique acétique, Fr.; *Zeitlosen-Essigextrakt*, G.

Preparation.—Take of Colchicum Root in moderately fine powder twelve troyounces; Acetic Acid four fluidounces; Water a sufficient quantity. To the acetic acid add a pint of water, and mix the resulting liquid with the colchicum root. Transfer the mixture to a conical glass percolator, and pour water gradually upon it, until the liquid passes with little or no taste. Lastly, evaporate the liquid, in a porcelain vessel, by means of a water-bath, to the proper consistence. *U. S.*

The formula of the British Pharmacopœia is the same as for the preceding extract, the only difference consisting in the addition of 6 fluidounces of acetic acid to the bruised colchicum tubers before the juice is expressed.

The extract resembles the preceding in all respects, except that it is softer and has the distinct odor of acetic acid.

Medical Uses.—These extracts are convenient forms of colchicum for prescription in pill, especially for those purgative pills which gouty patients commonly require. The *dose* of either is from one-half grain to two grains.

EXTRACTUM COLOCYNTHIDIS, *U. S.*, *P. G.*—EXTRACT OF COLOCYNTH.

Extractum colocynthidis alcoholicum.—*Extrait de coloquinte*, Fr.; *Koloquinten-Extrakt*, G.

Preparation.—Take of Colocynth forty-eight troyounces; Diluted Alcohol a sufficient quantity. Dry the colocynth, and, having removed the seeds, and reduced it to coarse powder by grinding or bruising, macerate it in eight pints of diluted alcohol for four days, with occasional stirring; then express strongly, and strain through flannel. Pack the residue, previously broken up with the hands, firmly in a cylindrical percolator, cover it with the strainer, and pour diluted alcohol upon it, until the tincture and expressed liquid, taken together, measure sixteen pints. Mix the tincture with the expressed liquid, and, having recovered from the mixture ten pints of alcohol by distillation, evaporate the residue to dryness by means of a water-bath. Lastly, reduce the dry mass to powder, and keep it in a well-stopped bottle. The extract obtained by this process weighs about seven troyounces. *U. S.*

The yield mentioned by the Pharmacopœia has reference to the peeled fruit containing the seeds, which, however, must be removed before percolation. When made on a large scale, the removal of the seeds is a tedious operation, if not impossible. For this reason the colocynth is ground, care being taken not to crush the seeds, which would load the extract with much oily matter. Dr. Squibb (1867) obtained from very dry colocynth 20.6 per cent. of extract; the general yield from the commercial article is about 14 to 14.5 per cent. After completely removing the seeds, Procter (1867) had left, from 48 troyounces of colocynth, only 12 troyounces of pulp, which yielded 3¼ troyounces of extract, equal to 6.8 per cent. G. H. C. Klie (1878) obtained 16 troyounces of pulp, and not over 6 troyounces, or 12.5 per cent., of extract.

Medical Uses.—It is seldom used alone, but is an ingredient of the compound extract.

EXTRACTUM COLOCYNTHIDIS COMPOSITUM, *U. S.*, *Br.*—COMPOUND EXTRACT OF COLOCYNTH.

Extrait de coloquinte composé, Fr.; *Zusammengesetztes Koloquinten-Extrakt*, G.

Preparation.—Take of Extract of Colocynth in fine powder three troyounces and a half; Purified Aloes in fine powder twelve troyounces; Resin of Scammony in fine powder three troyounces; Cardamom in fine powder a troyounce and a half; Soap in fine powder three troyounces. Mix the powders thoroughly, and keep the mixture in a well-stopped bottle. *U. S.*

Take of Colocynth Pulp six ounces; Extract of Socotrine Aloes twelve ounces; Resin of Scammony four ounces; Hard Soap in powder three ounces; Cardamom Seeds in fine powder one ounce; Proof Spirit one gallon. Macerate the colocynth in the spirit for four days; press out the tincture and distil off the spirit; then add the aloes, scammony, and soap, and evaporate by a water-bath until the extract is of a suitable consistence for forming pills; adding the cardamoms towards the end of the process. *Br.*

The first formula is preferable, as it directs the use of a definite amount of the extract of colocynth, instead of the extract obtained from a definite weight of colocynth pulp, which may vary considerably (see page 567). By mixing the ingredients in the state of fine powder, a preparation uniform in appearance cannot be obtained. But by fusing them together with the assistance of a little alcohol, and by subsequently drying and powdering, an unobjectionable compound extract is produced. It is not hygroscopic, and is, therefore, most conveniently kept in the state of powder.

Medical Uses.—As an efficient and safe purgative this compound, when well prepared, is not excelled by any other in cases of habitual *constipation* produced by torpor of the bowels. Calomel or rhubarb can be added to it to meet special indications; or, if disposed to gripe, extract of hyoscyamus will help to correct this tendency. The *dose* is from five to twenty grains.

EXTRACTUM CONII, *U. S.*, *Br.*—EXTRACT OF CONIUM.

Extract of hemlock, E.; *Extrait de ciguë*, Fr.; *Schierlings-Extrakt*, G.

Preparation.—Take of Conium Leaves fresh twelve troyounces. Bruise the leaves in a stone mortar, sprinkling on them a little water, and express the juice; then, having heated this to the boiling point, filter it, and evaporate to the proper consistence, either in a vacuum with the aid of heat, or in shallow vessels, at the ordinary temperature, by means of a current of air directed over the surface of the liquid. *U. S.*

The extract of the British Pharmacopœia is prepared from the fresh leaves and young branches of conium in precisely the same manner as the corresponding inspissated juices of aconite and belladonna.

This and the following extract might well be dispensed with. If a solid extract is desirable, it should be made from the nearly ripe fruit. The inspissated juice is about 5 per cent. of the weight of the recent herb.

Medical Uses.—As usually sold this extract is often inert. Two grains may be given, as a commencing dose, several times a day, and the quantity gradually increased until its proper operation begins to be seen.

EXTRACTUM CONII ALCOHOLICUM, *U. S.*—ALCOHOLIC EXTRACT OF CONIUM.

Alcoholic extract of hemlock, E.; *Extrait alcoolique de ciguë*, Fr.; *Spirituöses Schierlings-Extrakt*, G.

Preparation.—Take of Conium Leaves recently dried and in fine powder twelve troyounces; Alcohol a pint; Diluted Alcohol a sufficient quantity. Introduce the powder, previously mixed with one-third of the alcohol, into a conical percolator, and pour upon it the remainder of the alcohol. When the liquid has all been absorbed by the powder, pour diluted alcohol upon it until a pint of tincture has been obtained. Set this aside in a warm place, and allow it to evaporate spontaneously until reduced to three fluidounces. Continue the percolation with diluted alcohol until two pints more of tincture have passed, or until the powder is exhausted; then evaporate this liquid by means of a water-bath, at a temperature not exceeding 160° F., to the consistence of syrup. To this add the three fluidounces of tincture first obtained, and continue the evaporation, at a temperature not exceeding 120° F., until the whole is reduced to the proper consistence. *U. S.*

The yield is in the neighborhood of 20 per cent. of the dried leaves.

Medical Uses.—The primary *dose* of about two grains may be gradually increased until its operation becomes manifest.

EXTRACTUM DIGITALIS, *U. S.*, *Ph. G.*—EXTRACT OF DIGITALIS.

Extractum digitalis alcoholicum.—*Extrait alcoolique de digitale*, Fr.; *Fingerhut-Extrakt*, G.

Preparation.—Take of Digitalis recently dried and in fine powder twelve troyounces; Alcohol a pint; Diluted Alcohol a sufficient quantity. Introduce the powder, previously mixed with one-third of the alcohol, into a percolator, and pour upon it the remainder of the alcohol. When the liquid has all been absorbed by the powder, pour diluted alcohol upon it until a pint of tincture has been obtained. Set this aside in a warm place, and allow it to evaporate spontaneously until reduced to three fluidounces. Continue the percolation with diluted alcohol until two pints more of tincture have passed, or until the powder is exhausted; then evaporate this liquid, by means of a water-bath, at a temperature not exceeding 160° F., to the consistence of syrup. To this add the three fluidounces of tincture first obtained, and continue the evaporation, at a temperature not exceeding 120° F., until the whole is reduced to the proper consistence. *U. S.*

This is a greenish-brown extract, 22 to 25 parts of which represent 100 parts of the leaves. The inspissated juice, prepared according to the German Pharmacopœia (see page 556), is brown, and its weight is equal to that of 3 to 4 parts of the fresh leaves and branches employed.

Medical Uses.—This preparation is rarely used, and probably is less reliable than others of digitalis. *Dose*, one-fourth of a grain, and gradually increased.

EXTRACTUM DULCAMARÆ, *U. S.*, *P. G.*—EXTRACT OF BITTERSWEET.

Extrait de douce-amère, Fr.; *Bittersüss-Extrakt*, G.

Preparation.—Take of Bittersweet in moderately fine powder twelve troyounces; Diluted Alcohol a sufficient quantity. Moisten the bittersweet with four fluidounces of diluted alcohol, pack it in a conical percolator, and pour diluted alcohol gradually upon it until the tincture passes but slightly imbued with the properties of the bittersweet. Distil off the alcohol from the tincture until reduced to one-half; then strain, and, by means of a water-bath, evaporate to the proper consistence. *U. S.*

The German Pharmacopœia exhausts bittersweet by hot aqueous infusion. In both cases a brown extract, weighing about 20 per cent. of the twigs employed, is obtained.

Medical Uses.—This extract, which, when fresh, probably contains all the virtues of dulcamara, may be given in the *dose* of five or ten grains, and rapidly increased.

EXTRACTUM GENTIANÆ, *U. S.*, *Br.*—EXTRACT OF GENTIAN.

Extrait de gentiane, Fr.; *Enzian-Extrakt*, G.

Preparation.—Take of Gentian in moderately coarse powder twelve troyounces; Water a sufficient quantity. Moisten the gentian with four fluidounces of water, pack it in a conical percolator, and gradually pour water upon it until the infusion passes but slightly imbued with the properties of the gentian. Boil the liquid to three-fourths of its bulk; then strain, and, by means of a water-bath, evaporate to the proper consistence. *U. S.*

Take of Gentian Root sliced one pound; Boiling Distilled Water one gallon. Infuse the gentian in the water for two hours; boil for fifteen minutes; pour off, press, and strain. Then evaporate the liquor by a water-bath until the extract is of a suitable consistence for forming pills. *Br.*

Cold water is preferable for exhausting gentian, since it dissolves all of the bitter principle without taking up the whole of the pectin compounds, which enter into solution in hot water. An extract prepared with the latter has a gelatinous appearance, though not in the same degree as if made by prolonged boiling with water. The yield by the first process approaches 30 per cent. of the weight of the dry root, and the yellowish-brown extract yields with water a nearly clear solution.

Medical Uses.—This extract contains all the virtues of gentian in a form convenient for administration. It is, however, most generally used as an excipient for other tonics, and especially for iron and quinia. The *dose* is from three to ten grains.

EXTRACTUM GLYCYRRHIZÆ, *U. S.*—LIQUORICE.

Succus liquiritiæ, P. G.; *Extractum liquiritiæ.—Licorice, Extract of liquorice*, E.; *Extrait de réglisse*, Fr.; *Lakriz, Lakrizensaft*, G.

The extract of the root of Glycyrrhiza glabra, *Lin.*

Preparation.—Liquorice is prepared for commercial purposes in the southern portion of Europe, and in this country. The fresh root is mostly employed, but the dried root will likewise answer the purpose. The root is crushed to a pulpy mass or broken into a coarse powder, and then boiled with water over a naked fire, or by steam. The liquor is expressed, allowed to settle, and decanted, or for the common qualities together with the fine pulpy matter evaporated by boiling and continued stirring until the mass has attained the proper consistence to be rolled out into sticks of a certain weight, a portion of olive oil being used to prevent it from adhering to the hands and the table. The sticks are made of an adopted length and thickness, stamped with the initials or name of the manufacturer, or of the town where the factory is located, and finally dried. The root of *Glyc. echinata* is likewise used in the manufacture of liquorice.

On exhausting the root with cold or hot water, hygroscopic extracts are obtained; but on treating the root now with steam Delondre (1856) observed that a considerable amount of matter was dissolved, which, on evaporating the solution, was friable, without attracting moisture, and had a sweet taste without acridity. It is this substance, consisting of altered glycyrrhizin, together with the starch contained in the root, which gives firmness to the commercial extract. From 1,000,000 to 1,250,000 pounds of liquorice are annually imported into the United States, and a considerable quantity is manufactured here.

Description.—Liquorice appears in commerce packed in boxes between layers of laurel leaves (*Laurus nobilis*, Lin.) to prevent the sticks from adhering; in Southern Russia oak leaves are used for the same purpose. Besides the liquorice of American manufacture, two principal varieties are distinguished in our commerce, the *Sicilian* and *Calabrian* or *Spanish*. The former is in thin sticks, one-quarter to three-eighths of an inch in diameter, of a dull-black color, frequently of an empyreumatic taste, and generally very impure. The latter variety is in larger sticks, about an inch in diameter, six or seven inches long, black, and somewhat glossy externally, slightly flexible, except at a low temperature, and breaking with a sharp conchoidal and shining fracture; some small cavities may usually be found in the interior. The products of the different manufacturers of this liquorice differ from one another not only in the size of the stick, but often by marked differences in their odor and taste; while some specimens are almost purely sweet, others are persistently acrid and empyreumatic. For medicinal purposes, liquorice should be almost devoid ot acridity.

Placed in cold water, a portion of the liquorice is dissolved, but the residue retains the shape of the sticks, and if a little ammonia be now added to the water, Rump (1855) observed the liquid to become again colored and again to acquire a sweet taste from dissolving fresh portions of glycyrrhizin. The amount soluble in cold water varies very considerably, and reaches in the best brands about 70 per cent. of the dried liquorice, but the percentage is usually a little less than this.

Under the name of *Italian liquorice* an impure article in thin sticks is met with, and the so-called *refined liquorice* of the shops is in still thinner cylindrical and glossy pieces, likewise impure, and readily attacked by insects. *Pontefract cakes* are small liquorice lozenges, which are much used in England.

Impurities and Adulterations.—Fragments of vegetable tissue are generally present to some extent; shreds of copper are sometimes also met with, and result from careless scraping of the evaporating pans. The fraudulent additions usually consist of farinaceous matters, gum, glucose, and mineral compounds. The latter are estimated in the ash, which for good well-dried liquorice should not exceed 6 or 7 per cent.; starch may sometimes be seen in little lumps in the interior of the sticks, and if not altered by heat may be recognized by the microscope. Gum added fraudulently is usually detected in the cold aqueous solution by the precipitate which takes place on the addition of an equal bulk of alcohol, and grape-sugar will cause the solution of liquorice in cold water to be of a lighter color.

Corigliano and *Barracco* are among the brands most esteemed in the United States; *Solazzi* juice is highly valued in England.

Constituents.—Liquorice contains glycyrrhizin, free (soluble in ammonia) and in combination with ammonia (soluble in cold water); also starch, principally modified by long boiling, a portion of sugar, and a little acrid resinous matter.

Other extracts of liquorice:

EXTRACTUM GLYCYRRHIZÆ DEPURATUM s. SUCCUS LIQUIRITIÆ DEPURATUS, *Purified liquorice*, is recognized by several European Pharmacopœias, and has been proposed in the United States as a substitute for the powdered liquorice when ordered in liquid preparations. It is made by alternately placing layers of washed straw and liquorice into a suitable vessel, and covering the material with cold water. As the water becomes saturated it is withdrawn through a faucet below, and replaced by fresh water until color and a sweet taste are no longer imparted to it. The perfectly clear liquids are then evaporated to the consistence of an extract, which should yield a clear solution with water. For convenience in dispensing, a concentrated solution of definite strength is often kept on hand. To remove the resinous matter, which imparts a disagreeable acrid taste, Ungewitter (1875) suggests the digesting of the stick liquorice in strong alcohol, and afterwards exhausting it with cold water.

EXTRACTUM GLYCYRRHIZÆ, *Br.*, EXTRACTUM LIQUIRITIÆ RADICIS, *P. G.*—The extracts of liquorice root of the two pharmacopœias are alike and practically identical with that of the French Codex, except that the latter exhausts the root by displacement with distilled water at a temperature of 15° to 20° C. (59° to 68° F.); the following is the formula:—

Take of Liquorice Root in coarse powder one pound; Distilled Water four pints. Macerate the liquorice root with two pints of the water for twelve hours, strain and press; again macerate the pressed marc with the remainder of the water for six hours, strain and press. Mix the strained liquors, heat them to 100° C. (212° F.), and strain through flannel; then evaporate by a water-bath until the extract is of a suitable consistence for forming pills. *Br.*

The yield is about 16 per cent. The extract resembles the preceding *purified* extract of liquorice, but is of a lighter color, and of a sweet and purer taste.

Off. Prep.—Confectio sennæ, Decoct. aloes comp., *Br.;* Mistura glycyrrh. comp., *U. S.;* Mistura sennæ comp., *Br.;* Pil. ferri iodidi, *U. S.;* Tinct. aloes, *U. S.*, *Br.;* Tinct. rhei et sennæ, Troch. cubebæ, Troch. glycyrrh. et opii, *U. S.;* Troch. opii, *Br.*

Medical Uses.—Extract of liquorice is a lenitive and demulcent, which also excites the secretions of the fauces, and perhaps of the larynx. It is chiefly employed in irritable conditions of these parts, in *sore-throat*, *laryngitis*, and *bronchitis*. It may be conveniently used by allowing small fragments to dissolve in the mouth, or by adding it to the various syrups, lozenges, and mixtures appropriate to this purpose. It sometimes appears to prevent *flatulence* depending upon fermentation of the food, for which purpose a piece as large as a grain of wheat may be taken after meals.

EXTRACTUM HÆMATOXYLI, *U. S.*, *Br.*—EXTRACT OF LOGWOOD.

Extractum ligni campechiani, P. G.—*Extrait de bois Campêche*, Fr.; *Campecheholz-Extrakt*, G.

Preparation.—Take of Logwood rasped twelve troyounces; Water eight pints. Mix, and, having boiled to four pints, strain the decoction while hot; then evaporate to dryness. *U. S.*

Take of Logwood in fine chips one pound; Boiling Distilled Water one gallon. Infuse the logwood in the water for twenty-four hours; then boil down to one-half, strain, and evaporate to dryness by a water-bath, stirring with a wooden spatula. Iron vessels should not be used. *Br.*

The yield is about 12 per cent. The extract is not hygroscopic; it is of a red-brown color, and a sweet, afterwards astringent taste. It yields, with water, a red and almost clear solution. It is prepared on a large scale for uses in the arts. For composition compare *Hæmatoxylon*.

Medical Uses.—The extract has the medicinal qualities of the wood, and does not lose them by keeping. It may be administered in *doses* of ten grains or more, and in solution rather than in pills, which in time grow very hard.

EXTRACTUM HELLEBORI, *U. S.*—EXTRACT OF BLACK HELLEBORE.

Extractum hellebori nigri.—*Extrait d'ellebore noir*, Fr.; *Schwarze Niesswurz-Extrakt*, G.

Preparation.—Take of Black Hellebore recently dried and in fine powder twelve troyounces; Alcohol a pint; Diluted Alcohol a sufficient quantity. Introduce the powder, previously mixed with one-third of the alcohol, into a conical percolator, and pour upon it the remainder of the alcohol. When the liquid has all been absorbed by the powder, pour on diluted alcohol until a pint of tincture has been obtained. Set this aside in a warm place, and allow it to evaporate spontaneously until reduced to three fluidounces. Continue the percolation with diluted alcohol until two pints more of tincture have passed, or until the powder is exhausted; then evaporate, by means of a water-bath, at a temperature not exceeding 160° F., to the consistence of syrup. To this add the three fluidounces of tincture first obtained, and continue the evaporation at a temperature not exceeding 120° F., until the whole is reduced to the proper consistence. *U. S.*

This extract has been dismissed from most Pharmacopœias, on account of its inefficiency, which was owing to the aqueous or weak alcoholic menstruum, which is not adapted for exhausting the active principles. In France the extract is made with 60 per cent. alcohol.

Medical Uses.—The harshness of the purgative operation of black hellebore is such that its extract is seldom prescribed unless associated with other less active cathartics, or with aromatic stimulants. *Dose*, as a purgative, from five to ten grains.

EXTRACTUM HYOSCYAMI, *U. S.*, *Br.*—EXTRACT OF HYOSCYAMUS.

Extrait de jusquiame, Fr.; *Bilsenkraut-Extrakt*, G.

Preparation.—Take of Hyoscyamus Leaves fresh twelve troyounces. Bruise the leaves in a stone mortar, sprinkling on them a little water, and express the juice; then, having heated this to the boiling point, strain and evaporate to the proper consistence. *U. S.*

The British Pharmacopœia directs the extract to be made from fresh leaves and branches of hyoscyamus, like the extracts of aconite and belladonna. The yield is about 4 per cent.

The above extracts differ in color and consistency like the corresponding extracts of aconite and belladonna leaves; they retain to some extent the odor of the herb. The crystals observed in old extract, according to Attfield (1862), are potassium nitrate.

Medical Uses.—This preparation is notoriously one of the most variable in strength of all narcotic extracts. Its minimum *dose*, of two grains, should be rapidly increased until the characteristic effects of the medicine are produced.

EXTRACTUM HYOSCYAMI ALCOHOLICUM, *U. S.*—ALCOHOLIC EXTRACT OF HYOSCYAMUS.

Extrait alcoolique de jusquiame, Fr.; *Spirituöses Bilsenkraut-Extrakt*, G.

Preparation.—Take of Hyoscyamus Leaves recently dried and in moderately fine powder twenty-four troyounces; Alcohol four pints; Water two pints; Diluted Alcohol a sufficient quantity. Mix the alcohol and water and moisten the powder with a pint of the mixture; then pack it firmly in a conical percolator, and gradually pour upon it the remainder of the mixture. Continue the percolation with diluted alcohol until the tincture measures six pints. Lastly, evaporate, by means of a water-bath, to the proper consistence. *U. S.*

The yield is about 16 per cent.; the color is greenish-brown.

Medical Uses.—This, like the common extract, is of uncertain strength, but is perhaps somewhat less variable. The *dose* is two grains, increased until it becomes efficient.

EXTRACTUM IGNATIÆ, *U. S.*—EXTRACT OF IGNATIA.

Extractum ignatiæ alcoholicum.—*Extrait de fève de Saint-Ignace*, Fr.; *Ignazbohnen-Extrakt*, G.

Preparation.—Take of Ignatia in fine powder twelve troyounces; Alcohol a sufficient quantity. Mix the ignatia with four fluidounces of alcohol, and allow the mixture to stand for an hour. Then introduce it into a cylindrical percolater, press it firmly, and gradually pour alcohol upon it until three pints of tincture have slowly passed. Distil off the alcohol, by means of a water-bath, until the tincture is reduced to half a pint, and evaporate this to the proper consistence. *U. S.*

Ignatia is exceedingly difficult to powder; the object is best accomplished on a small scale by somewhat crushing the seeds and then heating them with a little water until they become soft enough to be bruised, while still warm, into a pulpy mass, with which a little alcohol is incorporated. It may then be dried and powdered for displacement. The powdering may be omitted and the pulpy mass macerated in alcohol. When the liquor has been somewhat concentrated, a fatty matter separates which, according to the officinal directions, should not be removed, but well mixed with the extract. The yield is about 9 per cent.

Medical Uses.—The extract preserves all the medicinal qualities of ignatia, and may be prescribed in *doses* of half a grain three times a day, and cautiously increased.

EXTRACTUM JALAPÆ, *U. S.*, *Br.*—EXTRACT OF JALAP.

Extrait de jalap, Fr.; *Jalapen-Extrakt*, G.

Preparation.—Take of Jalap in moderately fine powder twelve troyounces; Alcohol four pints; Water a sufficient quantity. Introduce the powder, previously mixed with three fluidounces of alcohol, into a conical percolator, and gradually pour upon it the remainder of the alcohol. When the liquid ceases to pass, pour sufficient water upon the residue to keep its surface covered, until four pints of tincture have passed. Set this portion aside and continue the percolation until six pints of infusion have been obtained. Distil off the alcohol from the tincture, and evaporate the infusion until the liquids respectively have been brought to the consistence of honey; then mix them and evaporate to the proper consistence. *U. S.*

Take of Jalap in coarse powder one pound; Rectified Spirit four pints; Distilled Water one gallon. Macerate the jalap in the spirit for seven days, press out the tincture, then filter, and distil off the spirit, leaving a soft extract. Again macerate the residual jalap in the water for four hours, express, strain through flannel, and evaporate by a water-bath to a soft extract. Mix the two extracts, and evaporate at a temperature not exceeding 140° F. until it has acquired a suitable consistence for forming pills. *Br.*

No advantage whatever results from treating jalap with water after it has been exhausted by alcohol. 240 grains of such an aqueous extract were taken by A. B. Taylor (1864) in the course of 8 hours without producing any noticeable effect. Alcohol alone will yield between 12 and 18 per cent. of active extract; and cold water will subsequently extract 30 to 35 per cent. of inert matter, with which the officinal extract is uselessly diluted and incumbered. The supposed advantage is due to an erroneous conception of the statement that the aqueous extract was possessed of mild purgative and diuretic properties; this statement is correct as far as it applies to that portion of the aqueous extract soluble in alcohol, or, what is the same thing, to the aqueous extract of the alcoholic extract. Exhaustion with alcohol of about 70 per cent. would yield a much more efficient extract, but considerably less, and the dose would have to be correspondingly smaller.

Medical Uses.—This preparation contains all the virtues of jalap in about half the bulk, and may be substituted for it in all prescriptions. The *dose* is from ten to twenty grains.

EXTRACTUM JUGLANDIS, *U. S.*—EXTRACT OF BUTTERNUT.

Extrait d'écorce de noyer gris, Fr.; *Butternussrinden-Extrakt*, G.

Preparation.—Take of Butternut in moderately coarse powder twelve troyounces; Water a sufficient quantity. Moisten the butternut with four fluidounces of water, pack it in a conical percolator, and gradually pour water upon it until the infusion passes but slightly imbued with the properties of the butternut. Boil the liquid to three-fourths of its bulk; then strain, and, by means of a water-bath, evaporate to the proper consistence. *U. S.*

The process with cold water is preferable to boiling the bark with water; (see *Juglans*), but a more efficient preparation, it seems, could be obtained by the use of an alcoholic menstruum. The extract is of a deep blackish-brown color and bitter taste.

Medical Uses.—It is a mild cathartic in the dose of twenty or thirty grains, and is said to be peculiarly appropriate for relieving habitual costiveness.

EXTRACTUM KRAMERIÆ, *U. S.*, *Br.*—EXTRACT OF RHATANY.

Extractum ratanhæ, P. G.—*Extrait de ratanhia*, Fr.; *Ratanha-Extrakt*, G.

Preparation.—Take of Rhatany in moderately fine powder twelve troyounces; Water a sufficient quantity. Moisten the powder with four fluidounces of water, pack it in a conical percolator, and gradually pour water upon it until the infusion passes but slightly imbued with the astringent property of the rhatany. Heat the liquid to the boiling point, strain, and by means of a water-bath, at a temperature not exceeding 160°, evaporate to the proper consistence. *U. S.*

Take of Rhatany Root in coarse powder one pound; Distilled Water a sufficiency. Macerate the rhatany in a pint and a half of the water for twenty-four hours; then pack in a percolator, and add more distilled water, until twelve pints have been collected, or the rhatany is exhausted. Evaporate the liquor by a water-bath to dryness. *Br.*

It is important that the design of both formulas be carried out, namely, to exhaust the root with *cold* water. Hot water will yield about five per cent. more extract, which, however, is but incompletely soluble in water, while the officinal extract yields a somewhat turbid solution with warm water, but a clear solution in the presence of sugar. The amount of extract obtainable depends on the size of the rhatany root used, the woody part of which contains but little soluble matter, the average yield being about 12 per cent. of *dry* extract. It is of a reddish-brown color, glossy, resembling kino in appearance, and is not hygroscopic. Iron utensils must not be used in its preparation.

Medical Uses.—This extract is a convenient form of krameria in nearly all of the cases to which that medicine is appropriate. The *dose* is from five to twenty grains, the smaller dose being frequently repeated.

EXTRACTUM LACTUCÆ, *Br.*—EXTRACT OF LETTUCE.

Extractum lactucæ virosæ, P. G.; *Thridacium.*—*Extrait de tiges de laitue*, *Thridace*, Fr.; *Giftlattich-Extrakt*, G.

Preparation.—Take of the Flowering Herb of Lettuce one hundred and twelve pounds. Bruise in a stone mortar, and press out the juice; heat it gradually to 130° F., and separate the green coloring matter by a calico filter. Heat the strained liquor to 200° F. to coagulate the albumen, and again filter. Evaporate the filtrate by a water-bath to the consistence of a thin syrup; then add to it the green coloring matter previously separated, and stirring the whole together assiduously, continue the evaporation at a temperature not exceeding 140° F., until the extract is of a suitable consistence for forming pills. *Br.*

The formula is identical with that for the inspissated juices of the other narcotic herbs. The extract contains the chlorophyll, and is incompletely soluble in water. The German and French Pharmacopœias direct the removal of the chlorophyll, and obtain an extract of a dark-brown color, which yields with water a somewhat turbid solution. The yield is about 4 per cent. The extract is sometimes called *French lactucarium.*

Medical Uses.—Like all the medicinal preparations of lettuce, it is an extremely feeble hypnotic. *Dose*, five or more grains.

EXTRACTUM LUPULI.—EXTRACT OF HOP.

Extractum humuli.—*Extrait de houblon*, Fr.; *Hopfenextrakt*, G.

Preparation.—Take of Hop one pound; Rectified Spirit one and a half pint; Distilled Water one gallon. Macerate the hop in the spirit for seven days, press out the tincture, filter, and distil off the spirit, leaving a soft extract. Boil the residual hop with the water for one hour, press out the liquor, strain, and evaporate by a water-bath to the consistence of a soft extract. Mix the two extracts, and evaporate at a temperature not exceeding 140° F., until it has acquired a suitable consistence for forming pills. *Br.*

Medical Uses.—This preparation represents pretty well the virtues of hop. *Dose*, five grains, or more.

EXTRACTUM MEZEREI ÆTHEREUM, *Br.*—ETHEREAL EXTRACT OF MEZEREON.

Extrait éthéré de mézéréon (de garou), Fr.; *Ætherisches Seidelbast-Extrakt*, G.

Preparation.—Take of Mezereon Bark cut small one pound; Rectified Spirit eight pints; Ether one pint. Macerate the mezereon in six pints of the spirit for three days with frequent agitation; strain and press. To the residue of the mezereon add the remainder of the spirit, and again macerate for three days with frequent agitation; strain and press. Mix and filter the strained liquors, recover the greater part of the spirit by distillation, evaporate what remains to the consistence of a soft extract; put this into a stoppered bottle with the ether, and macerate for twenty-four hours, shaking them frequently. Decant the ethereal solution, recover part of the ether by distillation, and evaporate what remains to the consistence of a soft extract. *Br.*

Ether dissolves the acrid principle of mezereon, and is therefore well adapted for the preparation of an efficient extract, the yield of which is about 7 per cent. The same extract was formerly officinal upon the continent of Europe, but has been pretty generally abandoned in favor of the alcoholic extract, which is obtained in the first part of the above process, and has the advantage of remaining quite soft and of being more manageable when prescribed as an addition to ointments; its yield is about 14 per cent. of the weight of bark employed, and, like the ethereal extract, it is of a green color, and is insoluble in water.

Medical Uses.—It is a powerful irritant, and may be added to stimulant and rubefacient liniments and ointments to increase their power. It is an ingredient of the Compound liniment of mustard, Br. Ph.

EXTRACTUM NUCIS VOMICÆ, *U. S.*, *Br.*—EXTRACT OF NUX VOMICA.

Extractum strychni spirituosum, P. G.; *Extractum nucum vomicarum spirituosum (vel alcoholicum)*.—*Extrait de noix vomique*, Fr.; *Weingeistiges Krähenaugen-Extrakt*, G.

Preparation.—Take of Nux Vomica in fine powder twelve troyounces; Alcohol a sufficient quantity. Mix the nux vomica with four fluidounces of alcohol, and allow the mixture to stand for an hour. Then introduce it into a cylindrical percolator, and gradually pour alcohol upon it until the tincture passes without bitterness. Distil off the alcohol by means of a water-bath until the tincture is reduced to half a pint, and evaporate this to the proper consistence. *U. S.*

Take of Nux Vomica one pound; Rectified Spirit a sufficiency. Apply steam to the nux vomica until it is thoroughly softened, then dry rapidly and reduce to fine powder. Exhaust the powder by boiling it with successive portions of the spirit until the latter comes off nearly free from bitterness. Strain, distil off the spirit, and evaporate by a water-bath to the consistence of a soft extract. *Br.*

The remarks made concerning Extr. ignatiæ are nearly all applicable to this extract and to the manipulation needed for obtaining it. Where steam is available for the softening of the seeds, we would recommend that they be crushed or bruised while hot. In this way the rapid drying will be facilitated. Otherwise the process indicated on page 557 may be followed. The fatty matter contained in the seeds is taken up by the alcohol, and retains a portion of the alkaloids in solution; it is evidently not intended by either Pharmacopœia that it should be removed. Its incorporation with the extract is hastened if the tincture is evaporated to a thin syrupy consistence, when hot water should be added with constant stirring, and the mixture then evaporated with continual agitation. The extract will be somewhat greasy. If the Pharmacopœias would direct alcohol of about 70 per cent., all the alkaloids, with but little of the fat, would be dissolved, and the extract could be evaporated to dryness and powdered. The officinal extract is of a yellowish-brown color, and of an intensely bitter taste; its yield is about 10 per cent. of the weight of the seeds; with the weaker alcohol indicated only 7 to 8 per cent. are obtained. It contains about 6 per cent. of strychnia.

Medical Uses.—It is chiefly used as an ingredient of pills intended to overcome habitual atonic constipation. The primary *dose* is about half a grain; it may gradually be increased to two or three grains when the specific action of the drug is sought.

EXTRACTUM OPII, *U. S.*, *Br.*—EXTRACT OF OPIUM.

Extrait d'opium, *Extrait thebaïque*, Fr.; *Opiumextrakt*, G.

Preparation.—Take of Opium twelve troyounces; Water five pints. Cut the opium into small pieces, macerate it for twenty-four hours in a pint of water, and reduce it to a soft mass by trituration. Express the liquid from it, and with each of the four pints of water remaining successively treat the residue in the same manner. Having mixed the liquids, filter the mixture, and evaporate by means of a water-bath to the proper consistence. *U. S.*

Take of Opium in thin slices one pound; Distilled Water six pints. Macerate the opium in two pints of the water for twenty-four hours, and express the liquor. Reduce the residue of the opium to a uniform pulp, macerate it again in two pints of the water for twenty-four hours, and express. Repeat the operation a third time. Mix the liquors, strain through flannel, and evaporate by a water-bath until the extract has acquired a suitable consistence for forming pills. *Br.*

The maceration of the opium is to be effected at the mean temperature of about 60° F. At a higher temperature a larger amount of extract is obtained, but of an inferior quality. The expressed liquids may be set aside for some time to settle, and then at once be passed through a well-moistened filter without waiting until the maceration is completed with the whole amount of water. A flannel strainer is well adapted for the purpose if it is well moistened with water and the filtrate returned upon the strainer as long as it passes turbid. The evaporation is completed in the water-bath, and might very properly be continued until a dry extract remains, which may be rubbed into a reddish-brown powder. The yield is 55 to 60 per cent. of the *dry* opium employed, and should contain about 17 per cent. of morphia to correspond with opium of 10 per cent. morphia strength.

Denarcotized extract of opium is still occasionally employed. It may be obtained by agitating the concentrated infusion with two portions of ether, each time allowing the mixture to settle, and decanting the ether, which dissolves the narcotina, but not the morphia; the aqueous liquid is then evaporated as before. This extract is probably in no way superior to the officinal preparation.

Off. Prep.—Emplast. opii, *U. S.;* Extract. opii liquid., *Br.;* Suppos. opii, Suppos. plumbi et opii, Trochisci glycyrrh. et opii, *U. S.;* Troch. opii, Vinum opii, *Br.*

Medical Uses.—This preparation is essentially opium purified from its inert constituents. Its average *dose* is about half a grain.

EXTRACTUM PAPAVERIS, *Br.*—EXTRACT OF POPPIES.

Extrait de pavot, Fr.; *Mohnextrakt*, G.

Preparation.—Take of Poppy Capsules, dried, freed from the seeds, and coarsely powdered, one pound; Rectified Spirit two ounces; Boiling Distilled Water a sufficiency. Mix the poppy capsules with two pints of the water and infuse for twenty-four hours, stirring them frequently; then pack them in a percolator, and, adding more of the water, allow the liquor slowly to pass until about a gallon has been collected, or the poppies are exhausted. Evaporate the liquor by a water-bath until it is reduced to a pint, and, when cold, add the spirit. Let the mixture stand for twenty-four hours, then separate the clear liquor by filtration, and evaporate this by a water-bath until the extract has acquired a suitable consistence for forming pills. *Br.*

Warm water extracts, with the medicinal principles, also the mucilaginous matters which are but imperfectly precipitated by the small quantity of alcohol added.

Medical Uses.—This extract appears to be unnecessary. It has no virtues that are not more decided in the various preparations of opium. *Dose*, from two to five grains.

EXTRACTUM PAREIRÆ, *Br.*—EXTRACT OF PAREIRA.

Extrait de pareira brava, Fr.; *Pareira-Extrakt*, G.

Preparation.—Take of Pareira Root in coarse powder one pound; Boiling Distilled Water one gallon or a sufficiency. Digest the pareira with a pint of the water for twenty-four hours, then pack in a percolator, and adding more of the water, allow the liquor slowly to pass until a gallon has been collected, or the pareira is exhausted. Evaporate the liquor by a water-bath until the extract has acquired a suitable consistence for forming pills. *Br.*

The use of boiling water, followed by prolonged digestion, must result in the solution of the starch, which is but imperfectly removed by the subsequent percolation. A diluted alcohol would seem to be a very appropriate menstruum for exhausting pareira.

Medical Uses.—The solid form of a medicine intended to act upon the mucous membrane of the urinary passages cannot be an eligible one. The fluid extract and the decoction are greatly preferable. *Dose*, from ten to twenty grains.

EXTRACTUM PHYSOSTIGMATIS, *U. S.*, *Br.*—EXTRACT OF CALABAR BEAN.

Extractum fabæ Calabaricæ, P.G.—*Extrait de fève de Calabar*, Fr.; *Kalabarbohnen-Extrakt*, G.

Preparation.—Take of Calabar Bean in moderately fine powder twelve troyounces; Alcohol a sufficient quantity. Moisten the powder with four fluidounces of alcohol, pack it in a conical percolator, and pour on half a pint of alcohol. Cork and closely cover the percolator, and set it aside in a moderately warm place for four days. Then having removed the cork, proceed with the percolation, and gradually pour on alcohol, until two pints of tincture have been obtained, or the bean has been exhausted. Distil off a pint and a half of alcohol from the tincture, and evaporate the remainder, by means of a water-bath, to the consistence of a soft extract. *U. S.*

Take of Calabar Bean in coarse powder one pound; Rectified Spirit four pints. Macerate the bean for forty-eight hours with one pint of the spirit in a close vessel, agitating occasionally, then transfer to a percolator, and when the fluid ceases to pass, add the remainder of the spirit so that it may slowly percolate through the powder. Subject the residue of the bean to pressure, adding the pressed liquid to the product of the percolation; filter, distil off most of the spirit, and evaporate what is left in the retort by a water-bath to the consistence of a soft extract. *Br.*

Calabar bean may be obtained in a sufficiently fine powder by drying it well and grinding it in a coffee-mill. The yield is about 6 per cent. of a greenish-brown extract, containing fatty matter, which will be left behind if alcohol of about 70 per cent. is used for exhausting the seeds. Kennedy (1875) suggested the addition of glycerin to the extract to keep it soft and to render it more convenient for manipulation.

Medical Uses.—The extract represents all the active constituents of Calabar bean. Its average *dose* may be stated at one-tenth of a grain.

EXTRACTUM PODOPHYLLI, *U. S.*—Extract of May Apple.

Extrait de podophylle, Fr.; *Fussblattwurzel-Extrakt*, G.

Preparation.—Take of May Apple in moderately fine powder twelve troyounces; Alcohol two pints; Diluted Alcohol a sufficient quantity. Introduce the powder, previously mixed with three fluidounces of alcohol, into a conical percolator, and pour upon it the remainder of the alcohol. When the tincture ceases to pass, pour gradually upon the powder sufficient diluted alcohol to keep its surface covered, until two pints of tincture have passed. Set this portion aside, and continue the percolation until two pints more of tincture have been obtained. Distil off the alcohol from the tinctures and evaporate them until the liquids respectively have been brought to the consistence of thin honey; then mix them, and evaporate to the proper consistence. *U. S.*

This formula is an improvement on that of the former Pharmacopœia, which directed the use of water after the powder had been extracted by alcohol Alcohol alone appears to deprive the drug completely of medicinal properties, and the subsequent exhaustion with diluted alcohol seems to be as unnecessary as with water.

Medical Uses.—The operation of this medicine closely resembles that of extract of jalap, and may be used for the same purposes in the *dose* of from five to twenty grains.

EXTRACTUM QUASSIÆ, *U. S.*, *Br.*—Extract of Quassia.

Extrait de quassie (*bois amer*), Fr.; *Quassia-Extrakt*, G.

Preparation.—Take of Quassia in moderately fine powder twelve troyounces; Water a sufficient quantity. Moisten the quassia with four fluidounces of water, pack it in a conical percolator, and gradually pour water upon it until the infusion passes but slightly imbued with the properties of the quassia. Boil the liquid to three-fourths of its bulk; then strain, and, by means of a water-bath, evaporate to the proper consistence. *U. S.*

Take of Quassia Wood rasped one pound; Distilled Water a sufficiency. Macerate the quassia with eight fluidounces of the water for twelve hours; then pack in a percolator, and adding more of the water, allow the liquor slowly to pass until the quassia is exhausted. Evaporate the liquor; filter before it becomes too thick; and again evaporate by a water-bath until the extract is of a suitable consistence for forming pills. *Br.*

The yield is about 4 or 5 per cent. J. S. Whall (1874) observed that one part of quassia is practically exhausted by obtaining from it four parts of percolate, and will yield rather less than 3½ per cent. of extract if water, or a little more if diluted alcohol is used; the latter is considered preferable. The yield is increased to about 6 or 7 per cent. if boiling water is used; but the extract has a jelly-like appearance, probably from pectin compounds.

Medical Uses.—The intense bitterness of this preparation denotes its possession of the virtues of quassia in a concentrated state. Like all other stomachic tonics, it should not be given in that form unless in a very small *dose*, such as one or two grains, and then usually associated with tonics of another order, *e. g.*, quinia, iron, etc.

EXTRACTUM RHEI, *U. S.*, *Br.*—EXTRACT OF RHUBARB.

Extractum rhei alcoholicum.—Extrait de rhubarbe, Fr.; *Rhabarber-Extrakt*, G.

Preparation.—Take of Rhubarb in moderately fine powder twelve troyounces; Alcohol a pint; Diluted Alcohol a sufficient quantity. Moisten the powder with four fluidounces of the alcohol, pack it in a conical percolator, and gradually pour upon it, first the remainder of the alcohol, and then diluted alcohol, until twelve fluidounces of tincture have been obtained. Set this portion aside in a warm place, and allow it to evaporate spontaneously until reduced to six fluidounces. Continue the percolation with diluted alcohol until the tincture passes nearly tasteless. Evaporate this in a porcelain vessel, by means of a water-bath, at a temperature not exceeding 160° F., to the consistence of syrup. With this mix the tincture first obtained, and continue the evaporation until the mixture is reduced to the proper consistence. *U. S.*

Take of Rhubarb Root sliced or bruised one pound; Rectified Spirit ten fluidounces; Distilled Water five pints. Mix the spirit and the water, and macerate the rhubarb in the mixture for four days; then decant, press, and set by, that the undissolved matter may subside; pour off the clear liquor, filter the remainder, mix the liquors, and evaporate by a water-bath, at a temperature not exceeding 160° F., until the extract has acquired a suitable consistence for forming pills. *Br.*

Weak alcohol and even cold water are well adapted for obtaining an efficient extract from rhubarb, though this is more completely exhausted by the first process. The yield is usually near 30 per cent., and varies with the quality of the rhubarb.

Medical Uses.—Owing to the difficulty of obtaining this preparation of good quality, it is scarcely to be preferred to good rhubarb root. Its *dose*, as a purgative, is from ten to twenty grains.

EXTRACTUM SENEGÆ, *U. S.*—EXTRACT OF SENEKA.

Extrait de polygale de Virginie, Extrait de sénéca, Fr.; *Senegaextrakt*, G.

Preparation.—Take of Seneka in moderately fine powder twelve troyounces; Diluted Alcohol a sufficient quantity. Moisten the powder with four fluidounces of diluted alcohol, pack it in a conical percolator, and gradually pour upon it diluted alcohol until three pints of tincture have passed. Evaporate this, by means of a water-bath, to the proper consistence. *U. S.*

The yield is about 30 per cent.; the extract is brown, has the acrid taste of the root, and may be conveniently kept in the state of powder.

Medical Uses.—This is a medicine very seldom prescribed, but which might perhaps be found advantageous in combination with squill in the decline of bronchial catarrhs. The *dose* is from one to three grains.

EXTRACTUM STRAMONII FOLIORUM, *U. S.*—EXTRACT OF STRAMONIUM LEAVES.

Extrait de feuilles de stramoine, Fr.; *Stechapfelkraut-Extrakt*, G.

Preparation.—Take of Stramonium Leaves recently dried and in fine powder twelve troyounces; Alcohol a pint; Diluted Alcohol a sufficient quantity. Introduce the powder, previously mixed with one-third of the alcohol, into a conical percolator, and gradually pour upon it the remainder of the alcohol. When the liquid has all been absorbed by the powder, pour on diluted alcohol until a pint of tincture has been obtained. Set this aside in a warm place, and allow it to evaporate spontaneously until reduced to three fluidounces. Continue the percolation with diluted alcohol until two pints more of tincture have passed, or until the powder is exhausted; then evaporate, by means of a water-bath, at a temperature not exceeding 160° F., to the consistence of syrup. With this mix the three fluidounces of tincture first obtained, and continue the evaporation, at a temperature not exceeding 120° F., until the mixture is reduced to the proper consistence. *U. S.*

It is strange that the Pharmacopœia should order inspissated juices to be prepared from narcotic herbs which rarely or never grow spontaneously in the United States, and not of the one which is a common weed in many sections of the country. The yield is about 20 per cent. of a greenish-brown extract. The fresh leaves and tops of stramonium yield nearly 3½ per cent. of inspissated juice free from albuminous compounds.

Medical Uses.—This extract possesses all the virtues of stramonium. It may be prescribed in the *dose* of one grain two or three times a day until its specific effects are exhibited.

EXTRACTUM STRAMONII SEMINIS, *U. S.*—EXTRACT OF STRAMONIUM SEED.

Extractum stramonii, Br.—*Extract of stramonium*, Br.; *Extrait de semences de stramoine*, Fr.; *Stechapfelsamen-Extrakt*, G.

Preparation.—Take of Stramonium Seed in moderately fine powder sixteen troyounces; Diluted Alcohol a sufficient quantity. Moisten the stramonium seed with four fluidounces of diluted alcohol, pack it in a conical percolator, and pour on twelve fluidounces of diluted alcohol. When the liquid begins to pass from the percolator, close the lower orifice with a cork, and, having closely covered the percolator, set it aside in a moderately warm place for four days. Then remove the cork, and gradually pour on diluted alcohol until two pints of tincture have been obtained, or until the tincture passes but slightly imbued with the properties of the stramonium. Distil off the alcohol from the tincture, and, by means of a water-bath, evaporate to the proper consistence. *U. S.*

Take of Stramonium Seeds in coarse powder one pound; Ether one pint, or a sufficiency; Distilled Water, Proof Spirit, each a sufficiency. Shake the ether in a bottle with half a pint of the water, and after separation decant the ether. Pack the stramonium in a percolator, and free it from its oil by passing the washed ether slowly through it. Having removed it and rejected the ethereal solution, pour the spirit over the residue of the stramonium in the percolator, and allow it to pass through slowly until the powder is exhausted. Distil off most of the spirit from the tincture, and evaporate the residue by a water-bath until the extract has acquired a suitable consistence for forming pills. *Br.*

The ether directed by the British Pharmacopœia removes the fixed oil of the seeds, which would otherwise remain in the extract. Petroleum-benzin would answer the same purpose, and have the advantage of cheapness. The yield is about 12½ per cent.

Medical Uses.—This extract is reckoned to be twice as strong as that of stramonium leaf, and its commencing *dose* should not exceed half a grain.

EXTRACTUM TARAXACI, *U. S.*, *Br.*—EXTRACT OF DANDELION.

Extrait de dent de lion, Fr.; *Löwenzahn-Extrakt*, G.

Preparation.—Take of Dandelion gathered in September sixty troyounces. Slice the dandelion, and bruise it in a stone mortar, sprinkling on it a little water, until reduced to a pulp. Then express and strain the juice, and evaporate it in a vacuum, or in a shallow dish over a water-bath, to the proper consistence. *U. S.*

Take of Fresh Dandelion Root four pounds. Crush the root, press out the juice, and allow it to deposit; heat the clear liquor to 212° F., and maintain the temperature for ten minutes; then strain, and evaporate by a water-bath at a temperature not exceeding 160° F., until the extract has acquired a suitable consistence for forming pills. *Br.*

The juice of taraxacum contains albumen which is very properly removed in the second process by heating the juice for a short time to the boiling point, and straining from the coagulum. Collected in the autumn the fresh root yields 9 to 10 per cent. of extract; the spring root yields a smaller amount. The extract is of a brown color, and should yield a nearly clear solution with water.

Medical Uses.—Owing to its liability to spoil, this extract is not an eligible preparation. It may be prescribed in the dose of half a drachm and upwards, dissolved in some aromatic water, and taken after meals.

EXTRACTUM VALERIANÆ, *U. S.*—EXTRACT OF VALERIAN.

Extrait de valériane, Fr.; *Baldrian-Extrakt*, G.

Preparation.—Take of Valerian in fine powder twelve troyounces; Alcohol a pint; Diluted Alcohol a sufficient quantity. Moisten the powder with four fluidounces of alcohol, pack it in a percolator, and gradually pour upon it the remainder of the alcohol. When the liquid has all been absorbed by the powder, pour on diluted alcohol until a pint of tincture has been obtained. Set this aside in a warm place, and allow it to evaporate spontaneously until reduced to three fluidounces. Continue the percolation with diluted alcohol until two pints more of tincture have passed, and evaporate, by means of a water-bath, to the consistence of syrup. Lastly, mix the two liquids, and continue the evaporation, at a temperature not exceeding 120° F., until the mixture is reduced to the proper consistence. *U. S.*

The object of the Pharmacopœia, to retain in the extract most of the volatile oil, is accomplished by the manipulation. The first portion of the tincture contains this oil, and is for that reason concentrated at a moderate temperature, at which the evaporation is also finally completed. The yield is about 20 per cent. The extract is of a deep brown color, has the odor of valerian, and dissolves only partially in water, but almost completely in diluted alcohol.

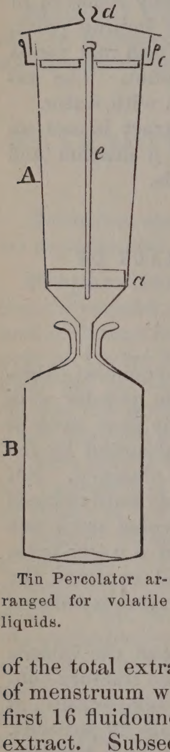
Medical Uses.—This extract is far inferior to the liquid preparations of valerian. Its average *dose* of twenty grains, coupled with its offensive taste, renders it inappropriate for obtaining the specific effects of valerian. It may be used with a possible slight advantage as a pilular excipient of quinia, nux vomica, and various nerve tonics.

EXTRACTA FLUIDA.—Fluid Extracts.

Extracta liquida.—Liquid extracts, E.; *Extraits liquides*, Fr.; *Flüssige Extrakte*, G.

Fluid or liquid extracts, in the meaning of the United States and British Pharmacopœias, are permanent concentrated solutions of vegetable drugs, made of such a strength that, in the United States, one fluidounce contains the medicinal principles, and represents the virtues, of one troyounce of the drug. The liquid extracts of former Pharmacopœias of Continental Europe, which are still occasionally described under their older officinal title *Mellago*, were solutions of extracts in water, made in proportion of three, or sometimes two parts of the former to one of the latter; they can be kept unaltered for a short time only, and are best prepared extemporaneously. The liquid extracts of the British Pharmacopœia vary in relative strength; one fluidounce (imperial measure) of some represents one avoirdupois ounce of the drug, of another two ounces, and different proportions in the remainder.

Fig. 69.



Tin Percolator arranged for volatile liquids.

Preparation.—The fluid extracts are made by percolation, and by concentrating the weakest percolate to a certain measure. The Pharmacopœia, very properly, orders a *suitable* percolator to be used, while for tinctures the use of a *conical*, and for extracts a *cylindrical* percolator is generally directed. The latter form, slightly diminishing in diameter towards the bottom, is also the one best adapted for the preparation of fluid extracts, although good results may, by careful management, be obtained with the funnel-shaped percolator. Dr. Squibb (1866) proved that in exhaustion by percolation there is a sufficient degree of uniformity of results to admit of the adoption of a model plan of proceeding applicable to drugs in general; second, that the extract or soluble matter yielded to the menstruum is not uniform in its chemical and therapeutical value, as obtained during the different stages of the percolation, but diminishes in effective value far more rapidly than the extract does in weight; and third, that this decrease in value depends upon the difference in solubility between the active and inactive portions of the extract, and that the ratio of this decrease is about the same for drugs in general, provided the proper menstruum be used. Critical experiments made with seven different drugs proved that the first twelve fluidounces of the percolate contained from 61 to 78 per cent. of the total extract obtainable with the much larger (than the present) amount of menstruum which was directed by the Pharmacopœia of 1860, and that the first 16 fluidounces contained from 71 to 84 per cent. of the total amount of extract. Subsequently (1869) Samuel Campbell showed that some drugs may be practically exhausted by careful management, on obtaining one fluidounce for every troyounce of the drug used. This principle, however, is applicable to those drugs only which are rather heavy, and at the same time are readily permeated by a menstruum in which the active principles are easily and freely soluble. With such, complete exhaustion is attained before the quantity of percolate directed by the Pharmacopœia (in most cases 24 fluidounces for 16 troyounces of the drug) has been obtained. The formulas of the Pharmacopœia require the first 14 fluidounces of percolate to be reserved, and the displacement to be continued until 10 fluidounces more are obtained, which, by evaporation, are reduced to two fluidounces, and then mixed with the reserved portion.

The manipulation is as follows: The powder is to be uniformly moistened with the specified quantity of menstruum, and well packed in the percolator. As usual, ligneous material requires to be very firmly packed, and when of more loose cellular structure the packing should be less firm; but in all cases it should be uniform. Again, when an alcoholic menstruum is used, the packing must be correspondingly firmer, as the menstruum is stronger in alcohol. When well packed, a disk of paper or muslin is spread upon the surface, and enough menstruum poured upon it to make sixteen fluidounces, including the portion used for moistening the powder. The liquid is allowed to penetrate the powder, and, if the latter is very dense and ligneous, will commence to drop from the percolator, the lower orifice of which should then be closed by a cork. Sixteen fluidounces of menstruum will not be sufficient to pass through a light powder; no more, however, should be added; but when it has been completely absorbed, the upper and lower orifice of the percolator should be closed to prevent evaporation, and the material allowed to macerate. One or two days will be ample time for this purpose, if all precautions have been properly attended to; but four days' maceration, as directed by the Pharmacopœia, will secure better results than a shorter period in the hands of the less skilful. Before percolation is properly started, the packing of the powder should be examined again, and, if necessary, adjusted by applying the requisite pressure upon the surface of the material, after which the cork is removed and more menstruum poured upon the disk until altogether about 28 fluidounces have been used, when its alcoholic strength may be gradually reduced until finally water is used for pushing the last portions of the percolate through. The more mucilaginous the material is, the greater the caution which should be exercised in this decrease of the alcoholic strength.

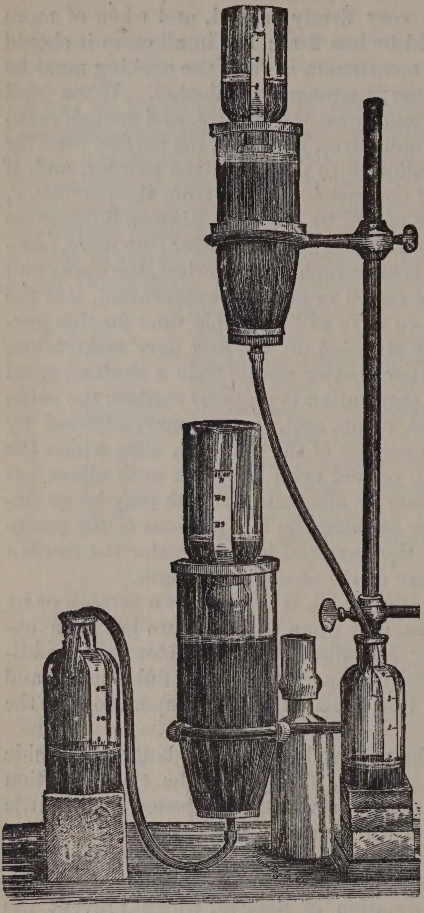
The percolate is collected in a pint bottle, which is marked by a scratch or by a strip of paper to indicate 14 fluidounces, and when that measure has been obtained the receiving vessel is changed for the collection of 10 fluidounces of additional percolate, which should be carefully evaporated to two fluidounces, and then mixed with the reserved portion. See remarks on the evaporation of the extracts (page 558).

After mixing the concentrated with the reserved portion, the bottle is set aside for a day or two, decanted from the sediment, if any, and the turbid portion passed through a small filter which has been previously dampened with a little alcohol. Filtration of the entire product will be rarely necessary.

The maceration of the material with the menstruum, as directed by the Pharmacopœia, is, in the majority of cases, accompanied by the complete absorption of the latter by the former, and the formation of fissures, which prevent the satisfactory percolation and exhaustion of the powder. The fissures are mostly removed by pressing the material again, before more menstruum is added; but, with proper precautions, it is evident from the results obtained by J. U. Lloyd, Dr. Squibb, and A. Robbins (1878), that the use of a larger quantity of menstruum in the beginning, sufficient to permeate the material, is advantageous. Using a sufficiency of liquid to completely expel the air, circulatory percolation is established during the prolonged maceration, the densest solutions, containing the largest proportion of principles, descending to the lowest part of the apparatus.

In 1866 Dr. Squibb recommended the process of *repercolation*, and has more recently somewhat modified it with the view of obtaining more uniform results, the object being preparation of fluid extracts without the use of heat. The process may be briefly described as follows: 32 parts of powder are divided into 4 equal portions, one of which is moistened, packed, macerated, and then slowly displaced until exhausted. The percolate is collected in fractions, the first 6 parts being reserved, and the next fraction used for moistening the second portion of 8 parts of the powder, which is afterwards macerated and displaced with the remaining fractions, the weakest being used last. Of this portion 8 parts of percolate are reserved. The third and fourth portions of 8 parts each of the powder are percolated in the same manner as the second portion, and, finally, the 4 reserved percolates are mixed to obtain 30 parts of fluid extract. The weaker percolates from the fourth portion are preserved for a subsequent operation, when from each portion of 8 parts of powder 8 parts of percolate are reserved.

Fig. 70.



Glass Percolators, with supply and receiving bottles.

A series of percolators may be conveniently arranged on a retort stand, and the rapidity of percolation regulated, as suggested by Dr. Squibb, by connecting the lower aperture of the percolator with a thin rubber tube, the end of which is raised high enough to prevent the liquid from escaping during maceration, and afterwards lowered, so that the percolation may proceed in drops, the position of the rubber tube being changed, to insure uniformity and regularity; the last portions of the liquid are withdrawn from the percolator, either by removing the rubber tube or by straightening it by sufficiently elevating the percolator. A uniform supply of menstruum may be provided for in various ways, the most simple of which is to invert a bottle containing the requisite quantity of liquid over the orifice of the percolator. The mouth of the bottle should be immediately above the disk covering the powder, and, if necessary, may be lengthened by a piece of rubber tubing.

The best *shape of the percolator* for preparing fluid extracts is the cylindrical form, somewhat narrowed towards the lower end, so as to represent a section of a long cone, which is closed below by a well-fitting cork, or it may terminate in the shape of a funnel. The relative proportion of *diameter to height* of powder is of importance, since it is evident that, with an increase of the latter, the same fraction of menstruum must come into contact with a larger number of particles of the powder. Its height should be 4 or 5 times greater than its diameter. The *cover* of the percolator should not fit air-tight, or, if from the volatility of the menstruum, this should be desirable, a communication should be established by means of a glass tube between the receiving vessel and the top of the percolator, for the equalization of pressure. Gum-cloth furnishes a convenient material for an ordinary cover.

Percolators may be made of any material which does not chemically react with the dissolved principles. In the majority of cases tin-percolators are unobjectionable. For some purposes, however, it is preferable to make the percolators of glass.

The *strength of fluid extracts* depends solely on the amount of the active principles, and not on the total amount of extractive matter contained in solution. Menstrua, which are best adapted to permanently dissolve the former in their natural combinations, and, at the same time, exclude the inert principles, are best adapted for the purposes the Pharmacopœia has in view. There can be no doubt that there is room for improvement in many of the formulas; however, but few critical observations on the best menstrua have been published.

A process for the preparation of fluid extracts without the use of heat deserves a passing notice, since from the employment of a very powerful press it is, perhaps, better adapted for the manufacturer than for the pharmacist. It was devised by N. S. Thomas (1865), and consists in moistening the ground drug with a portion of the menstruum, and, after sufficient maceration, expressing the liquid. The operation of maceration and expressing is repeated several times, until the proper quantity of fluid extract is obtained.

Fluid extracts should be kept in well-corked bottles which are not too large. The preparations, properly made, will fairly represent the drugs, and necessarily must vary to some extent in their efficacy; but the variation should be only within the limits of the variation which is unavoidable in the crude material.

EXTRACTUM BELÆ LIQUIDUM, *Br.*—LIQUID EXTRACT OF BAEL.

Extrait liquide de bael, Fr.; *Flüssiges Baelextrakt*, G.

Preparation.—Take of Bael Fruit one pound; Distilled Water twelve pints; Rectified Spirit two fluidounces. Macerate the bael for twelve hours in one-third of the water; pour off the clear liquor; repeat the maceration a second and third time for one hour in the remaining two-thirds of the water; press the marc, and filter the mixed liquors through flannel. Evaporate to fourteen fluidounces, and, when cold, add the rectified spirit. *Br.*

This fluid extract represents one avoirdupois ounce of bael in each fluidounce imperial measure. The amount of spirit seems very small for such a concentrated liquid.

Medical Uses.—This fluid extract is regarded as the most efficient form for the administration of bael, and is used chiefly in chronic diarrhœa and dysentery, and in atonic disorders of the stomach. *Dose*, one or two fluidrachms.

EXTRACTUM BELLADONNÆ RADICIS FLUIDUM, *U.S.*—FLUID EXTRACT OF BELLADONNA ROOT.

Extrait liquide de racine de belladonne, Fr.; *Flüssiges Tollkirschenwurzel-Extrakt*, G.

Preparation.—Take of Belladonna Root in moderately fine powder sixteen troyounces; Glycerin four fluidounces; Alcohol, Water, each a sufficient quantity. Mix twelve fluidounces of alcohol, three fluidounces of glycerin, and one fluidounce of water, and, having moistened the belladonna root with four fluidounces of the mixture, proceed according to directions given in the general formula at page 585. Finish the percolation with diluted alcohol, and having reserved fourteen fluidounces, add one fluidounce of glycerin to the remainder of the percolate, before evaporation. *U. S.*

Care should be taken that the root be not too woody. The use of alcohol alone would seem to be preferable; the preparation could then be used in making belladonna plaster. (See page 520.)

Medical Uses.—The *dose* of this preparation is from three to five minims. It is one of the most efficient representatives of belladonna.

EXTRACTUM BUCHU FLUIDUM, *U. S.*—FLUID EXTRACT OF BUCHU.

Extrait liquide de bucco, Fr.; *Flüssiges Buccoextrakt*, G.

Preparation.—Take of Buchu in moderately fine powder sixteen troyounces; Alcohol a sufficient quantity. Moisten the buchu with six fluidounces of alcohol, and proceed according to directions given in the general formula at page 585. *U. S.*

This is a very concentrated tincture, and, if properly made, fairly represents the drug. The leaves should be carefully powdered to avoid loss of the volatile oil.

Medical Uses.—This fluid extract is inferior to the infusion of buchu for diseases of the urinary organs; but in default of that preparation may be prescribed in *doses* of twenty or thirty minims very largely diluted with water.

EXTRACTUM CALUMBÆ FLUIDUM, *U. S.*—FLUID EXTRACT OF COLUMBO.

Extrait liquide de colombo, Fr.; *Flüssiges Kolomboextrakt*, G.

Preparation.—Take of Columbo in fine powder sixteen troyounces; Glycerin two fluidounces; Alcohol, Water, each a sufficient quantity. Mix the glycerin with fourteen fluidounces of alcohol, and, having moistened the columbo with four fluidounces of the mixture, proceed according to directions given in the general formula at page 585. Finish the percolation with a menstruum consisting of two parts of alcohol and one part of water. *U. S.*

The use of a stronger alcohol would be of advantage, and tend to render the preparation more permanent.

Medical Uses.—It is a convenient substitute for the infusion, and may be prescribed in doses of a fluidrachm in two fluidounces of water.

EXTRACTUM CHIMAPHILÆ FLUIDUM, *U. S.*—FLUID EXTRACT OF PIPSISSEWA.

Extrait liquide de pyrole ombellée, Fr.; *Flüssiges Doldenmangold-Extrakt*, G.

Preparation.—Take of Pipsissewa in moderately fine powder sixteen troyounces; Glycerin four fluidounces; Alcohol, Water, each a sufficient quantity. Mix half a pint of alcohol, three fluidounces of glycerin, and five fluidounces of water, and, having moistened the pipsissewa with half a pint of the mixture, proceed according to directions given in the general formula at page 585. Finish the percolation with diluted alcohol, and, having reserved fourteen fluidounces, add one fluidounce of glycerin to the remainder of the percolate, before evaporation. *U. S.*

The fluid extract has the sensible properties of the leaves in a high degree.

Medical Uses.—This preparation is less eligible than the decoction. *Dose*, a fluidrachm, largely diluted, three or four times a day.

EXTRACTUM CIMICIFUGÆ FLUIDUM, *U. S.*—FLUID EXTRACT OF CIMICIFUGA.

Extrait liquide d'actée à grappes, Fr.; *Flüssiges Cimicifuga-Extrakt*, G.

Preparation.—Take of Cimicifuga in very fine powder sixteen troyounces; Stronger Alcohol a sufficient quantity. Moisten the cimicifuga with four fluidounces of stronger alcohol, and proceed according to directions given in the general formula at page 585. *U. S.*

This has all the sensible properties of the drug from which it was made, and is a permanent preparation.

Medical Uses.—This preparation is greatly preferable to the decoction, which was formerly used. *Dose*, from thirty minims to a fluidrachm.

EXTRACTUM CINCHONÆ FLUIDUM, *U. S.*—FLUID EXTRACT OF CINCHONA.

Extractum cinchonæ flavæ liquidum, Br.; *Extractum Chinæ calisayæ fluidum.*—*Fluid extract of yellow cinchona or calisaya bark*, E.; *Extrait liquide de quinquina jaune*, Fr.; *Flüssiges Kalisayarinden-Extrakt*, G.

Preparation.—Take of Yellow Cinchona in very fine powder sixteen troyounces; Glycerin four fluidounces; Alcohol, Water, each a sufficient quantity. Mix half a pint of alcohol, three fluidounces of glycerin, and five fluidounces of water, and, having moistened the cinchona with five fluidounces of the mixture, proceed according to directions given in the general formula at page 585. Continue the percolation with diluted alcohol until two pints of tincture have been obtained, and having reserved fourteen fluidounces, add one fluidounce of glycerin to the remainder of the percolate, before evaporation. *U. S.*

Take of Yellow Cinchona Bark in coarse powder one pound; Distilled Water a sufficiency; Rectified Spirit one fluidounce. Macerate the cinchona bark in two pints of the water for twenty-four hours, stirring frequently; then pack in a percolator, and add more water, until twelve pints have been collected, or until the water ceases to dissolve anything more. Evaporate the liquor at a temperature not exceeding 160° F., to a pint; then filter through paper, and continue the evaporation to three fluidounces, or until the specific gravity of the liquid is at 1.200. When cold add the spirit gradually, constantly stirring. The specific gravity should be about 1.100. *Br.*

The first formula is decidedly the better, and if any improvement is desirable it would be in the first part of the process, where the water might be partly or wholly replaced by alcohol. Water alone will but partially exhaust cinchona bark, and during the long-continued evaporation a portion of the alkaloids will become insoluble through the alteration of the tannin. On the other hand, a stronger alcohol will dissolve more cinchonic red, but secure the more thorough exhaustion of the alkaloids. The product of the second formula cannot represent in each fluidounce the virtues of the four ounces of bark used, and there must necessarily be a considerable waste of valuable material.

Medical Uses.—An advantage of this preparation is, that it contains in solution all the active principles of cinchona, and not merely one or the other of the alkaloids. As a tonic it may be given in the *dose* of a fluidrachm. For securing the antiperiodic effects of cinchona, it is eligible only in mild cases of periodical fever; for severer ones it must be given in doses too bulky to be convenient.

EXTRACTUM COLCHICI RADICIS FLUIDUM, *U. S.*—Fluid Extract of Colchicum Root.

Extrait liquide de bulbe de colchique, Fr.; *Flüssiges Zeitlosenknollen-Extrakt*, *G.*

Preparation.—Take of Colchicum Root in moderately fine powder sixteen troyounces; Glycerin four fluidounces; Alcohol, Water, each a sufficient quantity. Mix twelve fluidounces of alcohol, three fluidounces of glycerin, and one fluidounce of water, and, having moistened the colchicum root with five fluidounces of the mixture, proceed according to directions given in the general formula at page 585, finishing the percolation with diluted alcohol, and, having reserved fourteen fluidounces, add one fluidounce of glycerin to the remainder of the percolate, before evaporation. *U. S.*

This fluid extract keeps well, and fully represents the drug from which it is prepared.

Medical Uses.—This preparation contains all the virtues of colchicum. *Dose*, from two to eight minims.

EXTRACTUM COLCHICI SEMINIS FLUIDUM, *U. S.*—Fluid Extract of Colchicum Seed.

Extrait liquide de semences de colchique, Fr.; *Flüssiges Zeitlosensamen-Extrakt*, G.

Preparation.—Take of Colchicum Seed in fine powder sixteen troyounces; Glycerin four fluidounces; Alcohol, Water, each a sufficient quantity. Mix twelve fluidounces of alcohol, three fluidounces of glycerin, and one fluidounce of water, and, having moistened the colchicum seed with four fluidounces of the mixture, proceed according to directions given in the general formula at page 585. Finish the percolation with diluted alcohol, and, having reserved fourteen fluidounces, add one fluidounce of glycerin to the remainder of the percolate, before evaporation. *U. S.*

The amount of fixed oil contained in colchicum seeds, renders the employment of a weaker alcohol desirable. This would probably be of no disadvantage, since the active principle is readily soluble in water, and its preservation insured by the glycerin and alcohol.

Medical Uses.—Like the preceding, this extract is a full representative of colchicum. *Dose*, from two to eight minims.

EXTRACTUM CONII FRUCTÛS FLUIDUM, *U. S.*—Fluid Extract of Hemlock Fruit.

Fluid extract of conium seed, E.; *Extrait liquide de fruit de ciguë*, Fr.; *Flüssiges Schierlingsfrucht-Extrakt*, G.

Preparation.—Take of Conium Seed in fine powder sixteen troyounces; Glycerin four fluidounces; Muriatic Acid one hundred and eighty grains; Alcohol, Water, each a sufficient quantity. Mix half a pint of alcohol, three fluidounces of glycerin, and five fluidounces of water, and, having moistened the conium seed with four fluidounces of the mixture, proceed according to directions given in the general formula at page 585. Finish the percolation with diluted alcohol, and, having reserved fourteen fluidounces, add the muriatic acid and one fluidounce of glycerin to the remainder of the percolate, before evaporation. *U. S.*

A fluid extract, prepared from the fully developed green fruit of conium, is preferable to that from the leaves which was formerly officinal. The muriatic acid is added to the portion to be evaporated for the purpose of preventing the evaporation of the readily volatile conia.

Medical Uses.—It is a convenient form, and, next to the juice, the most reliable, for the administration of conium. *Dose*, from one to three minims.

EXTRACTUM CORNÛS FLORIDÆ FLUIDUM, *U. S.*—FLUID EXTRACT OF DOGWOOD.

Extrait liquide de cornouiller à grandes fleurs, Fr.; *Flüssiges Kornelrinden-Extrakt*, G.

Preparation.—Take of Dogwood in fine powder sixteen troyounces; Glycerin four fluidounces; Alcohol, Water, each a sufficient quantity. Mix half a pint of alcohol, three fluidounces of glycerin, and five fluidounces of water, and having moistened the dogwood with five fluidounces of the mixture, proceed according to directions given in the general formula at page 585. Finish the percolation with diluted alcohol, and, having reserved fourteen fluidounces, add one fluidounce of glycerin to the remainder of the percolate, before evaporation. *U. S.*

This fluid extract represents the virtues of the bark, and keeps well.

Medical Uses.—This officinal preparation appears to be entirely superfluous. It may be given in the *dose* of a fluidrachm or more.

EXTRACTUM CUBEBÆ FLUIDUM, *U. S.*—FLUID EXTRACT OF CUBEB.

Extrait liquide de cubèbe, Fr.; *Flüssiges Cubeben-Extrakt*, G.

Preparation.—Take of Cubeb in moderately fine powder sixteen troyounces; Stronger Alcohol a sufficient quantity. Moisten the cubeb with six fluidounces of stronger alcohol, and proceed according to directions given in the general formula at page 585.

This fluid extract should not be confounded with the oleoresin of the same drug, which was formerly recognized as fluid extract; it contains the medicinally active resin, together with most of the volatile oil.

Medical Uses.—As a substitute for cubeb this preparation is of doubtful utility, except, perhaps, in chronic affections of the genito-urinary passages. *Dose*, from ten to thirty minims.

EXTRACTUM DIGITALIS FLUIDUM, *U. S.*—FLUID EXTRACT OF DIGITALIS.

Extrait liquide de digitale, Fr.; *Flüssiges Fingerhut-Extrakt*, G.

Preparation.—Take of Digitalis in moderately fine powder sixteen troyounces; Glycerin four fluidounces; Alcohol, Water, each a sufficient quantity. Mix twelve fluidounces of alcohol, three fluidounces of glycerin, and one fluidounce of water, and, having moistened the digitalis with half a pint of the mixture, proceed according to directions given in the general formula at page 585. Finish the percolation with diluted alcohol, and, having reserved fourteen fluidounces, add one fluidounce of glycerin to the remainder of the percolate, before evaporation. *U. S.*

This is a fair representative of digitalis leaves.

Medical Uses.—Its advantages over the tincture, and especially over the infusion, are not very apparent. The *dose* is one or two drops.

EXTRACTUM DULCAMARÆ FLUIDUM, *U. S.*—FLUID EXTRACT OF BITTERSWEET.

Extrait liquide de douce-amère, Fr.; *Flüssiges Bittersüss-Extrakt*, G.

Preparation.—Take of Bittersweet in moderately coarse powder sixteen troyounces; Glycerin four fluidounces; Alcohol, Water, each a sufficient quantity. Mix half a pint of alcohol, three fluidounces of glycerin, and five fluidounces of water, and, having moistened the bittersweet with six fluidounces of the mixture, proceed according to directions given in the general formula at page 585. Finish the percolation with diluted alcohol, and, having reserved fourteen fluidounces, add one fluidounce of glycerin to the remainder of the percolate, before evaporation. *U. S.*

The alcohol has been kept at as low a percentage as appeared to be consistent with the permanency of the preparation and with the medicinal properties of the medicine.

Medical Uses.—This fluid extract probably contains all the active elements of dulcamara, and may be prescribed in the *dose* of a fluidrachm, largely diluted and gradually increased.

EXTRACTUM ERGOTÆ FLUIDUM, *U. S.*, *Br.*—FLUID EXTRACT OF ERGOT.

Extrait liquide de seigle ergoté, Fr.; *Flüssiges Mutterkornextrakt*, G.

Preparation.—Take of Ergot in moderately fine powder sixteen troyounces; Glycerin four fluidounces; Acetic Acid half a fluidounce; Alcohol, Water, each a sufficient quantity. Mix half a pint of alcohol, three fluidounces of Glycerin, and five fluidounces of water, and, having moistened the ergot with four fluidounces of the mixture, proceed according to directions given in the general formula at page 585. Finish the percolation with diluted alcohol, and, having reserved fourteen fluidounces, add the acetic acid, and one fluidounce of Glycerin to the remainder of the percolate, before evaporation. *U. S.*

Take of Ergot in coarse powder one pound; Ether one pint, or a sufficiency; Distilled Water three and a half pints; Rectified Spirit eight fluidounces. Shake the ether in a bottle with half a pint of the water, and after separation decant the ether. Place the ergot in a percolator, and free it from its oil by passing the washed ether slowly through it. Remove the marc and digest it in three pints of the water at 160° F. for twelve hours. Press out, strain, and evaporate the liquor by the heat of a water-bath to nine fluidounces; when cold, add the spirit. Allow it to stand for an hour to coagulate, then filter. The product should measure sixteen fluidounces. *Br.*

The large quantity of fixed oil contained in ergot, and liable to be displaced by an alcoholic menstruum, is, in the second process, first exhausted by ether, for which a light petroleum benzin may perhaps be advantageously substituted. Both formulas yield efficient liquid preparations of ergot, of which, however, the first is not suited for concentration to be used for hypodermic injection; in that respect the second extract is preferable, or in its place a fluid extract made by exhausting the powdered ergot with diluted alcohol, omitting the glycerin in the first formula. The addition of acetic acid is made to prevent the volatilization of trimethylamin, but is of doubtful necessity as regards the medicinal effects of the preparation.

Off. Prep.—Vinum ergotæ, *U. S.*

Medical Uses.—This preparation represents the totality of the active elements of ergot. In cases of *uterine inertia* it may be prescribed in the *dose* of half a fluidrachm to a fluidrachm repeated every fifteen or twenty minutes. To counteract the effects of *spinal hyperæmia*, the commencing dose should not be less than two drachms three times a day, and it may be increased to three, or even four times that quantity.

EXTRACTUM ERIGERONTIS CANADENSIS FLUIDUM, *U. S.*—FLUID EXTRACT OF CANADA FLEABANE.

Extrait liquide d'érigeron du Canada, Fr.; *Flüssiges Canada-Berufskraut-Extrakt*, G.

Preparation.—Take of Canada Erigeron in moderately coarse powder sixteen troyounces; Alcohol a sufficient quantity. Moisten the erigeron with half a pint of alcohol, and proceed according to directions given in the general formula at page 585. *U. S.*

Alcohol is used for this fluid extract with the view of dissolving the volatile oil, to which its efficacy is mainly due.

Medical Uses.—The oil, which is the active principle of Canada fleabane, being wholly contained in this preparation, it fully represents the plant. The *dose* is from five to ten drops, on sugar, every hour or two.

EXTRACTUM FILICIS LIQUIDUM, *Br.* See OLEORESINÆ FILICIS.

EXTRACTUM GELSEMII FLUIDUM, *U. S.*—FLUID EXTRACT OF YELLOW JASMINE.

Extrait liquide de jasmine jaune, Fr.; *Flüssiges Gelber Jasmin-Extrakt*, G.

Preparation.—Take of Yellow Jasmine in very fine powder sixteen troyounces; Alcohol a sufficient quantity. Moisten the yellow jasmine with four fluidounces of alcohol, and proceed according to directions given in the general formula at page 585.

Alcohol is well adapted for exhausting gelsemium, and the fluid extract has the strong odor and bitter taste of the drug.

Medical Uses.—If used at all, for which there seems to be no necessity, great caution should be observed, on account of the profound and even fatal depression it has occasioned. The *dose* is from five to ten minims.

EXTRACTUM GENTIANÆ FLUIDUM, *U. S.*—FLUID EXTRACT OF GENTIAN.

Extrait liquide de gentiane, Fr.; *Flüssiges Enzianextrakt*, G.

Preparation.—Take of Gentian in moderately coarse powder sixteen troyounces; Glycerin four fluidounces; Alcohol, Water, each a sufficient quantity. Mix half a pint of alcohol, three fluidounces of glycerin, and five fluidounces of water, and, having moistened the gentian with four fluidounces of the mixture, proceed according to directions given in the general formula at page 585.

Finish the percolation with diluted alcohol, and, having reserved fourteen fluidounces, add one fluidounce of glycerin to the remainder of the percolate, before evaporation. *U. S.*

A fluid extract of gentian made with diluted alcohol and without glycerin, keeps very well, and the addition of glycerin does not seem either to improve or to impair its qualities.

Medical Uses.—It may be employed for all the purposes of the bitter tonics, but it is seldom prescribed alone. It may be used to reinforce the tonic properties of the compound tincture of gentian, and other liquid tonic preparations. *Dose*, half a fluidrachm.

EXTRACTUM GERANII FLUIDUM, *U. S.*—Fluid Extract of Geranium.

Extrait de bec-de-grue tacheté, Fr.; *Flüssiges Fleckenstorchschnabel-Extrakt*, G.

Preparation.—Take of Geranium in moderately fine powder sixteen troyounces; Glycerin four fluidounces; Alcohol, Water, each a sufficient quantity. Mix half a pint of alcohol, three fluidounces of glycerin, and five fluidounces of water, and, having moistened the geranium with four fluidounces of the mixture, proceed according to directions given in the general formula at page 585. Finish the percolation with diluted alcohol, and, having reserved fourteen fluidounces, add one fluidounce of glycerin to the remainder of the percolate, before evaporation. *U. S.*

A dark reddish-brown fluid extract in which the astringent properties of the drug appear to be well preserved.

Medical Uses.—Fluid extract of cranesbill is an excellent substitute for the liquid preparations of catechu and other simple astringents. *Dose*, from half a fluidrachm to one or two fluidrachms.

EXTRACTUM GLYCYRRHIZÆ FLUIDUM, *U. S.*—Fluid Extract of Liquorice Root.

Extractum glycyrrhizæ liquidum, Br. Add.—*Liquid extract of liquorice root*, E.; *Extrait liquide de réglisse*, Fr.; *Flüssiges Süssholz-Extrakt*, G.

Preparation.—Take of Liquorice Root in fine powder sixteen troyounces; Glycerin four fluidounces; Alcohol, Water, each a sufficient quantity. Mix half a pint of alcohol, three fluidounces of glycerin, and five fluidounces of water, and, having moistened the liquorice root with four fluidounces of the mixture, proceed according to directions given in the general formula at page 585. Finish the percolation with diluted alcohol, and, having reserved fourteen fluidounces, add one fluidounce of glycerin to the remainder of the percolate, before evaporation. *U. S.*

Take of Liquorice Root in coarse powder one pound; Distilled Water four pints. Macerate the liquorice root with two pints of the water for twelve hours, strain and press; again macerate the pressed marc with the remainder of the water for six hours, strain and press. Mix the strained liquors, heat them to 212° F., and strain through flannel; then evaporate by a water-bath until it has acquired, when cold, a specific gravity of 1.160; add to this one-eighth of its volume of rectified spirit; let the mixture stand for twelve hours, and filter. *Br. Add.*

Both formulas yield fluid extracts containing the peculiar sweet taste of the liquorice root. The preparation was recommended by Jos. Harrop (1869) for disguising the bitter taste of quinia.

Medical Uses.—It is a very agreeable substitute for the simple extract of liquorice in flavoring cough medicines, and concealing acrid flavors.

EXTRACTUM GOSSYPII RADICIS FLUIDUM, *U. S.*—FLUID EXTRACT OF COTTON ROOT.

Extrait liquide d'écorce de cotonnier, Fr.; *Flüssiges Baumwollenwurzel-Extrakt*, G.

Preparation.—Take of Cotton Root in very fine powder sixteen troyounces; Glycerin four fluidounces; Alcohol, Water, each a sufficient quantity. Mix half a pint of alcohol, three fluidounces of glycerin, and five fluidounces of water, and, having moistened the cotton root with four fluidounces of the mixture, proceed according to directions given in the general formula at page 585. Finish the percolation with diluted alcohol, and, having reserved fourteen fluidounces, add one fluidounce of glycerin to the remainder of the percolate, before evaporation. *U. S.*

Properly prepared this fluid extract has a bright brownish-red color. Made according to the above formula it will sometimes thicken into a jelly-like substance, which is prevented by the use of a menstruum stronger in alcohol. J. U. Lloyd (1876) proposes to use a mixture of 10 fluidounces of alcohol, and three each of glycerin and water, and finish percolation with a menstruum composed of 10 fluidounces of alcohol and 6 of water. He also proposes to reserve the first 13 fluidounces of the percolate, and to evaporate the remainder to 3 fluidounces. Fresh or recently dried bark appears to yield a more effectual preparation than old bark.

Medical Uses.—It is used chiefly as a substitute for ergot, as an oxytocic and emmenagogue, and may be given in the *dose* of half a fluidrachm or more.

EXTRACTUM HYDRASTIS FLUIDUM, *U. S.*—FLUID EXTRACT OF HYDRASTIS.

Extrait liquide de hydrastis, Fr.; *Flüssiges Hydrastis-Extrakt*, G.

Preparation.—Take of Hydrastis in very fine powder sixteen troyounces; Glycerin two fluidounces; Alcohol, Water, each a sufficient quantity. Mix the glycerin with fourteen fluidounces of alcohol, and, having moistened the hydrastis with four fluidounces of the mixture, proceed according to directions given in the general formula at page 585. Finish the percolation with a menstruum consisting of two parts of alcohol and one part of water. *U. S.*

The fluid extract has a deep brown-yellow color, and the strongly bitter taste of the root.

Medical Uses.—This is a convenient and efficient form of the medicine. *Dose*, a fluidrachm two or three times a day.

EXTRACTUM HYOSCYAMI FLUIDUM, *U. S.*—FLUID EXTRACT OF HYOSCYAMUS.

Extrait liquide de jusquiame, Fr.; *Flüssiges Bilsenkraut-Extrakt*, G.

Preparation.—Take of Hyoscyamus Leaves in moderately fine powder sixteen troyounces; Glycerin four fluidounces; Alcohol, Water, each a sufficient quantity. Mix twelve fluidounces of alcohol, three fluidounces of glycerin, and one fluidounce of water, and, having moistened the hyoscyamus with half a pint of the mixture, proceed according to directions given in the general formula at page 585. Finish the percolation with diluted alcohol, and, having reserved fourteen fluidounces, add one fluidounce of glycerin to the remainder of the percolate, before evaporation. *U. S.*

This is made like the fluid extracts of other narcotic leaves, and has the heavy odor of the drug.

Medical Uses.—The fluid extract is a good representative of hyoscyamus, and may be prescribed in *doses* of from five to ten minims, and increased if necessary.

EXTRACTUM IPECACUANHÆ FLUIDUM, *U. S.*—FLUID EXTRACT OF IPECACUANHA.

Extrait liquide d'ipécacuanha, Fr.; *Flüssiges Ipecacuanha-Extrakt*, G.

Preparation.—Take of Ipecacuanha in fine powder sixteen troyounces; Glycerin half a pint; Stronger Alcohol a pint and a half; Water twelve fluidounces; Diluted Alcohol a sufficient quantity. Mix the stronger alcohol and water, and, having moistened the ipecacuanha with six fluidounces of the mixture, pack it firmly in a conical percolator, and pour upon it twelve fluidounces of the mixture. When the liquid begins to drop from the percolator, close the lower orifice with a cork, and, having closely covered the percolator, set it aside for four days. Then remove the cork, and gradually pour on the remainder of the mixture, and finally diluted alcohol, until two pints of tincture have slowly passed. Mix this portion with the glycerin, and evaporate the mixture, at a temperature not exceeding 140° F., to one pint. *U. S.*

A fluid extract, which should yield an almost clear mixture with simple syrup, as intended by the Pharmacopœia, can be obtained by the above formula only when working on quantities much smaller than directed. The following modification, worked out by R. V. Mattison (1873), yields more satisfactory results. The percolate is mixed with only two fluidounces of glycerin, evaporated, at a temperature not exceeding 140° F., to eleven fluidounces, allowed to cool, and thrown on a moistened filter. The residue upon the filter, which is of a resinous appearance, is washed with sufficient water to make the filtrate measure twelve fluidounces. Should a precipitate occur in the latter, a second filtration through a small filter is necessary, after which the preparation is brought to the measure of a pint by the addition of four fluidounces of glycerin. The six fluidounces of glycerin have been found quite sufficient to preserve the fluid extract.

Off. Prep.—Syrupus ipecacuanhæ, *U. S.*

Medical Uses.—Fluid extract of ipecacuanha is a convenient addition to expectorant mixtures, but hardly as much so as the syrup, to the preparation of which, indeed, it is essential. The *dose*, as an emetic, is about twenty or thirty minims; as an expectorant, five minims.

EXTRACTUM KRAMERIÆ FLUIDUM, *U. S.*—FLUID EXTRACT OF RHATANY.

Extrait liquide de ratanhia, Fr.; *Flüssiges Ratanha-Extrakt*, G.

Preparation.—Take of Rhatany in fine powder sixteen troyounces; Glycerin four fluidounces; Alcohol, Water, each a sufficient quantity. Mix half a pint of alcohol, three fluidounces of glycerin, and five fluidounces of water, and, having moistened the rhatany with four fluidounces of the mixture, proceed according to directions given in the general formula at page 585. Finish the percolation with diluted alcohol, and, having reserved fourteen fluidounces, add one fluidounce of glycerin to the remainder of the percolate, before evaporation. *U. S.*

This fluid extract is of a deep brown-red color, and strongly astringent taste.

Medical Uses.—It has the advantage over the tincture of being more astringent and less stimulant. *Dose*, half a fluidrachm.

EXTRACTUM LUPULINÆ FLUIDUM, *U. S.*—Fluid Extract of Lupulin.

Extrait liquide de lupuline, Fr.; *Flüssiges Lupulin-Extrakt*, G.

Preparation.—Take of Lupulin sixteen troyounces; Stronger Alcohol a sufficient quantity. Moisten the lupulin with six fluidounces of stronger alcohol, and proceed according to directions given in the general formula at page 585. *U. S.*

The use of stronger alcohol is necessary to keep the volatile oil and resinous matter in solution; the preparation fairly represents the drug.

Medical Uses.—It affords a convenient mode of administering lupulin. The *dose* is fifteen or twenty minims, which should be mixed with syrup, and afterwards diluted with water.

EXTRACTUM MATICO LIQUIDUM, *U. S.*—Fluid Extract of Matico.

Extrait liquide de matico, Fr.; *Flüssiges Matico-Extrakt*, G.

Preparation.—Take of Matico in moderately fine powder sixteen troyounces; Glycerin four fluidounces; Alcohol, Water, each a sufficient quantity. Mix twelve fluidounces of alcohol, three fluidounces of glycerin, and one fluidounce of water, and, having moistened the matico with half a pint of the mixture, proceed according to directions given in the general formula at page 585. Finish the percolation with diluted alcohol, and, having reserved fourteen fluidounces, add one fluidounce of glycerin to the remainder of the percolate, before evaporation. *U. S.*

The virtues of the drug are well preserved by the officinal menstruum.

Medical Uses.—The utility of this preparation consists in the facility with which it is absorbed. It may be given in *doses* of from half a fluidrachm to two fluidrachms.

EXTRACTUM MEZEREI FLUIDUM, *U. S.*—Fluid Extract of Mezereon.

Extrait liquide de Mézéréon (de garou), Fr.; *Flüssiges Seidelbast-Extrakt*, G.

Preparation.—Take of Mezereon in moderately coarse powder sixteen troyounces; Stronger Alcohol a sufficient quantity. Moisten the mezereon with six fluidounces of stronger alcohol, and proceed according to directions given in the general formula at page 585. *U. S.*

This fluid extract is used in the preparation of Unguentum mezerei, for which purpose it is very convenient.

Medical Uses.—Diluted, this extract may take the place of decoction of mezereon. But an overdose of it undiluted may give rise to violent and even fatal effects. Its chief use is its external application to maintain a discharge from blistered surfaces.

EXTRACTUM OPII LIQUIDUM. *Br.*—LIQUID EXTRACT OF OPIUM.

Extrait liquide d'opium, Fr.; *Flüssiges Opiumextrakt*, G.

Preparation.—Take of Extract of Opium one ounce; Distilled Water sixteen fluidounces; Rectified Spirit four fluidounces. Macerate the extract of opium in the water for an hour, stirring frequently; then add the spirit, and filter. The product should measure one pint (imperial). It contains 22 grains of extract of opium, nearly, in 1 fluidounce. *Br.*

This is, perhaps, slightly stronger in opium than the tincture of opium, and scarcely deserves to be classed with the fluid extracts; it is analogous to the Tinctura opii deodorata, *U. S.*

Medical Uses.—Essentially a solution of the watery extract of opium, this preparation is probably less apt to nauseate and constipate than laudanum. *Dose*, from ten to forty minims.

EXTRACTUM PAREIRÆ FLUIDUM, *U. S.*—FLUID EXTRACT OF PAREIRA BRAVA.

Extractum pareiræ liquidum, Br.—*Liquid extract of pareira*, E.; *Extrait liquide de pareira brava*, Fr.; *Flüssiges Pareira-Extrakt*, G.

Preparation.—Take of Pareira Brava in fine powder sixteen troyounces; Glycerin four fluidounces; Alcohol, Water, each a sufficient quantity. Mix half a pint of alcohol, three fluidounces of glycerin, and five fluidounces of water, and, having moistened the pareira brava with four fluidounces of the mixture, proceed according to directions given in the general formula at page 585. Finish the percolation with diluted alcohol, and, having reserved fourteen fluidounces, add one fluidounce of glycerin to the remainder of the percolate, before evaporation. *U. S.*

Take of Pareira Root in coarse powder one pound; Boiling Distilled Water one gallon, or a sufficiency; Rectified Spirit three fluidounces. Digest the pareira with a pint of the water for twenty-four hours; then pack in a percolator, and, adding more of the water, allow the liquor slowly to pass until a gallon has been collected, or the pareira is exhausted. Evaporate the liquor by a water-bath to thirteen fluidounces, and, when it is cold, add the spirit, and filter through paper. *Br.*

The latter formula gives a concentrated infusion, preserved by the addition of a little alcohol. The former extracts the root more readily by the use of an alcoholic menstruum. The brown-colored preparation possesses the peculiar bitter taste of the root in a marked degree.

Medical Uses.—This preparation probably contains all the medicinal qualities of pareira brava. It may be given in teaspoonful *doses* three times a day, largely diluted.

EXTRACTUM PRUNI VIRGINIANÆ FLUIDUM, *U. S.*—FLUID EXTRACT OF WILD CHERRY.

Extrait liquide de cerisier de Virginie, Fr.; *Flüssiges Wildkirschenrinden-Extrakt*, G.

Preparation.—Take of Wild Cherry in fine powder sixteen troyounces; Glycerin four fluidounces; Water half a pint; Stronger Alcohol a sufficient quantity. Mix the glycerin and water, and, having moistened the wild cherry with half a pint of the mixture, allow it to macerate in a covered vessel for four days; then pack it in a conical glass percolator, and pour on the remainder of the mixture; when this has disappeared from the surface, gradually pour on stronger alcohol until twelve fluidounces have been obtained, and set this portion aside. Continue the percolation with stronger alcohol until twenty fluidounces more have been obtained; evaporate to four fluidounces and filter through paper, rinsing the filter with a small portion of stronger alcohol, so as to preserve the measure of four fluidounces. Lastly, mix this with the reserved portion, and keep in a well-stopped bottle. *U. S.*

During the maceration of the powder with the aqueous liquid, the amygdalin of the bark is decomposed into hydrocyanic acid and volatile oil (benzaldehyd), a portion of both being contained in the reserved aqueous percolate. The finished preparation represents mainly the astringent and tonic virtues, and in part the sedative properties of wild cherry bark.

Medical Uses.—If well prepared, this extract represents more fully and in a more convenient form than any other preparation the virtues of wild cherry bark. It is an excellent adjuvant to cough mixtures in chronic *pulmonary* affections, and a palliative of *nervous* disorder of the heart's action. The *dose* is from thirty minims to a fluidrachm, and should be gradually increased.

EXTRACTUM RHEI FLUIDUM, *U. S.*—FLUID EXTRACT OF RHUBARB.

Extrait liquide de rhubarbe, Fr.; *Flüssiges Rhabarber-Extrakt*, G.

Preparation.—Take of Rhubarb in moderately fine powder sixteen troyounces; Glycerin two fluidounces; Alcohol, Water, each a sufficient quantity. Mix the glycerin with fourteen fluidounces of alcohol, and, having moistened the rhubarb with four fluidounces of the mixture, proceed according to directions given in the general formula at page 585. Finish the percolation with a menstruum consisting of two parts of alcohol and one part of water. *U. S.*

The rhubarb is well exhausted by the menstruum directed, the last portions of which may be pushed through by officinal diluted alcohol, but not by a more aqueous menstruum, which would swell the cellular tissue and stop percolation. The fluid extract has a blackish-brown color.

Off. Prep.—Syrupus rhei, *U. S.*

Medical Uses.—This preparation is not often used as a purgative; but its *dose* may be stated at from ten to thirty minims.

EXTRACTUM RUBI FLUIDUM, *U. S.*—FLUID EXTRACT OF BLACKBERRY.

Extrait liquide d'écorce de ronce, Fr.; *Flüssiges Brombeerrinden-Extrakt*, G.

Preparation.—Take of Blackberry in fine powder sixteen troyounces; Glycerin four fluidounces; Alcohol, Water, each a sufficient quantity. Mix half a pint of alcohol, three fluidounces of glycerin, and five fluidounces of water, and, having moistened the powdered bark with four fluidounces of the mixture, proceed according to directions given in the general formula at page 585. Finish the percolation with diluted alcohol, and, having reserved fourteen fluidounces, add one fluidounce of glycerin to the remainder of the percolate, before evaporation. *U. S.*

The bark of blackberry root is fairly exhausted, and the preparation well preserved by the menstruum ordered. The deep brown liquid has a decidedly astringent taste.

Off. Prep.—Syrupus rubi, *U. S.*

Medical Uses.—It is a good astringent, and well suited for the treatment of mild cases of *diarrhœa* in children, after a proper evacuation of the bowels. The *dose* is from half a fluidrachm to two fluidrachms. It may, like other vegetable astringents, be added to chalk mixture.

EXTRACTUM SABINÆ FLUIDUM, *U. S.*—FLUID EXTRACT OF SAVINE.

Extrait liquide de sabine, Fr.; *Flüssiges Sadebaum-Extrakt*, G.

Preparation.—Take of Savine in moderately fine powder sixteen troyounces; Stronger Alcohol a sufficient quantity. Moisten the savine with half a pint of stronger alcohol, and proceed according to directions given in the general formula at page 585. *U. S.*

The brown-green liquid contains the volatile oil, resin, and tannin of the drug, and is not only well adapted for making the officinal Ceratum sabinæ, *U. S.*, but it offers likewise a convenient way for administering savine.

Medical Uses.—The fluid extract appears to contain all the virtues of savine. *Dose*, from five to fifteen minims.

EXTRACTUM SARSAPARILLÆ FLUIDUM, *U. S.*—FLUID EXTRACT OF SARSAPARILLA.

Extractum sarsæ liquidum, Br.; *Liquid extract of sarsaparilla*, E.—*Extrait liquide de salsepareille*, Fr.; *Flüssiges Sarsaparilla-Extrakt*, G.

Preparation.—Take of Sarsparilla in moderately fine powder sixteen troyounces; Glycerin half a pint; Alcohol, Water, each a sufficient quantity. Mix half a pint of alcohol with four fluidounces each of glycerin and water, and, having moistened the sarsaparilla with four fluidounces of the mixture, proceed according to directions given in the general formula at page 585. Continue the percolation with diluted alcohol until twenty-six fluidounces have been obtained. Reserve the first ten fluidounces, and, having added four fluidounces of glycerin to the remainder of the percolate, carefully evaporate to six fluidounces, and mix with the reserved portion. *U. S.*

Take of Jamaica Sarsaparilla cut transversely one pound; Distilled Water at 160° F. fourteen pints; Rectified Spirit one fluidounce. Digest the sarsaparilla in one-half of the water for six hours, and decant the liquor. Digest the residue in the remainder of the water for the same time, express and filter the liquors, and evaporate them by a water-bath to seven fluidounces, or until the specific gravity of the liquid is 1.13. When cold, add the spirit. The specific gravity should be about 1.095. *Br.*

Of the two preparations, the latter is apparently double the strength of the former; but the long evaporation requisite for reducing nearly 280 to 7 fluidounces is of questionable benefit, even if the root had been completely exhausted by the warm water. The first process appears to be well adapted for exhausting the root, and preserving the fluid extract, which contains but little over one-fourth its measure of alcohol.

Medical Uses.—It probably contains whatever active elements belong to sarsaparilla, and serves as a basis, or a vehicle, for other medicines. *Dose*, from thirty minims to a fluidrachm.

EXTRACTUM SARSAPARILLÆ COMPOSITUM FLUIDUM, *U. S.*—COMPOUND FLUID EXTRACT OF SARSAPARILLA.

Extrait liquide de salsepareille composé, Fr.; *Zusammengesetztes flüssiges Sarsaparilla-Extrakt*, G.

Preparation.—Take of Sarsaparilla in moderately fine powder sixteen troyounces; Liquorice Root in moderately fine powder, Sassafras in moderately fine powder, each two troyounces; Mezereon in moderately fine powder three hundred and sixty grains; Glycerin half a pint; Alcohol, Water, each a sufficient quantity. Mix half a pint of alcohol with four fluidounces each of glycerin and water, and, having moistened with six fluidounces of the mixture the powders previously well mixed, proceed according to directions given in the general formula at page 585. Continue the percolation with diluted alcohol until two pints have been obtained. Reserve the first twelve fluidounces, and, having added four fluidounces of glycerin to the remainder of the percolate, carefully evaporate to six fluidounces, and mix with the reserved portion. *U. S.*

The frequent use which is made of the above combination of drugs probably renders such a fluid extract desirable, though it seems to be unnecessary, since the introduction of concentrated preparations of liquorice root and mezereon affords the opportunity of giving these and sarsaparilla in any proportion that may be desired.

Medical Uses.—The only very active ingredient in this preparation, after the sarsaparilla, is mezereon. It would appear to be a less eligible medicine than the compound decoction of sarsaparilla, which contains also guaiacum, and whose efficiency is established. *Dose*, from thirty minims to a fluidrachm.

EXTRACTUM SCILLÆ FLUIDUM, *U. S.*—FLUID EXTRACT OF SQUILL.

Extrait liquide de scille, Fr.; *Flüssiges Meerzwiebel-Extrakt*, G.

Preparation.—Take of Squill in moderately coarse powder sixteen troyounces; Glycerin two fluidounces; Alcohol, Water, each a sufficient quantity. Mix the glycerin with fourteen fluidounces of alcohol, and, having moistened the squill with four fluidounces of the mixture, proceed according to directions given in the general formula at page 585. Finish the percolation with a menstruum consisting of two parts of alcohol and one part of water. *U. S.*

The use of alcohol in the first part of the process prevents the excessive swelling of the squill which would take place with a more aqueous menstruum, and render impossible the approximate exhaustion of the drug with so small a quantity of menstruum as directed. The extract is of a deep red color.

Medical Uses.—This preparation is a concentrated and convenient form of squill. It is especially adapted for use as a diuretic. *Dose*, three or more minims, largely diluted.

EXTRACTUM SENEGÆ FLUIDUM, *U. S.*—FLUID EXTRACT OF SENEKA.

Extrait liquide de polygale de Virginie, Fr.; *Flüssiges Senegaextrakt*, G.

Preparation.—Take of Seneka in fine powder sixteen troyounces; Glycerin four fluidounces; Alcohol, Water, each a sufficient quantity. Mix half a pint of alcohol, three fluidounces of glycerin, and five fluidounces of water, and, having moistened the seneka with four fluidounces of the mixture, proceed according to directions given in the general formula at page 585. Finish the percolation with diluted alcohol, and, having reserved fourteen fluidounces, add one fluidounce of glycerin to the remainder of the percolate, before evaporation. *U. S.*

An alcoholic menstruum like that directed is better adapted for dissolving the acrid polygalic acid than one of greater alcoholic strength; but it has also the disadvantage of dissolving various pectin compounds which are apt after some time to convert the liquid into a gelatinous mass. This result is prevented by the use of a little alkali, for which purpose Dr. Squibb (1871) proposed about 2½ drachms of ammonia water, and H. N. Rittenhouse the same quantity of bicarbonate of sodium. The fluid extract is dark brown in color.

Medical Uses.—The special object of this preparation is apparently to supersede the decoction, all of whose virtues it possesses. *Dose*, half a fluidrachm.

EXTRACTUM SENNÆ FLUIDUM, *U. S.*—FLUID EXTRACT OF SENNA.

Extrait liquide de séné, Fr.; *Flüssiges Sennaextrakt*, G.

Preparation.—Take of Senna in fine powder sixteen troyounces; Glycerin half a pint; Alcohol, Water, each a sufficient quantity. Mix half a pint of alcohol with four fluidounces each of glycerin and water, and, having moistened the senna with half a pint of the mixture, proceed according to directions given in the general formula at page 585. Continue the percolation with diluted alcohol until twenty-six fluidounces have been obtained. Reserve the first ten fluidounces, and, having added four fluidounces of glycerin to the remainder of the percolate, carefully evaporate to six fluidounces, and mix with the reserved portion. *U. S.*

Thus prepared the fluid extract is an efficient preparation, containing less than one-fourth its measure of alcohol. It is of a dark-brown color, and has the odor and taste of senna leaves.

Off. Prep.—Extractum spigeliæ et sennæ fluidum. *U. S.*

Medical Uses.—This fluid extract may be prescribed as a laxative in *doses* of a fluidrachm, and as a purgative in doses of two or more fluidrachms. It is apt to gripe severely without the addition of a carminative, such as oil of anise or oil of peppermint.

EXTRACTUM SERPENTARIÆ FLUIDUM, *U. S.*—FLUID EXTRACT OF SERPENTARIA.

Extrait liquide de serpentaire, Fr.; *Flüssiges Schlangenwurz-Extrakt*, G.

Preparation.—Take of Serpentaria in fine powder sixteen troyounces; Alcohol a sufficient quantity. Moisten the serpentaria with four fluidounces of alcohol, and proceed according to directions given in the general formula at page 585. *U. S.*

The virtues of serpentaria are well exhausted and properly preserved by this process. The fluid extract has a red-brown color, and the peculiar odor and bitter taste of the drug.

Medical Uses.—It is a convenient and efficient substitute for the infusion of serpentaria. *Dose*, half a fluidrachm.

EXTRACTUM SPIGELIÆ ET SENNÆ FLUIDUM, *U. S.*—FLUID EXTRACT OF SPIGELIA AND SENNA.

Extrait liquide de spigélie et séné, Fr.; *Flüssiges Spigelien- und Senna-Extrakt*, G.

Preparation.—Take of Fluid Extract of Spigelia ten fluidounces; Fluid Extract of Senna six fluidounces; Oil of Anise, Oil of Caraway, each twenty minims. Mix the fluid extracts, and dissolve the oils in the mixture. *U. S.*

This compound fluid extract contains spigelia and senna in a proportion which has been used with satisfactory results for a number of years.

Medical Uses.—This preparation represents in a concentrated form the well-tried and popular remedy "worm-tea." It should be prescribed in *doses* of one or more fluidrachms at intervals of an hour until it begins to purge.

EXTRACTUM SPIGELIÆ FLUIDUM, *U. S.*—FLUID EXTRACT OF SPIGELIA.

Extrait liquide de spigélie, Fr.; *Flüssiges Spigelien-Extrakt*, G.

Preparation.—Take of Spigelia in fine powder sixteen troyounces; Glycerin half a pint; Alcohol, Water, each a sufficient quantity. Mix half a pint of alcohol with four fluidounces each of glycerin and water, and, having moistened the spigelia with four fluidounces of the mixture, proceed according to directions given in the general formula at page 585. Continue the percolation with diluted alcohol until twenty-six fluidounces have been obtained. Reserve the first ten fluidounces, and, having added four fluidounces of glycerin to the remainder of the percolate, carefully evaporate to six fluidounces, and mix with the reserved portion. *U. S.*

This is a dark-brown liquid, containing less than one-fourth its measure of alcohol, and representing the virtues of spigelia.

Off. Prep.—Extractum spigeliæ et sennæ fluidum.

Medical Uses.—It possesses fully the virtues of spigelia, and may be given in the *dose* of a fluidrachm and upwards.

EXTRACTUM STILLINGIÆ FLUIDUM, *U. S.*—FLUID EXTRACT OF STILLINGIA.

Extrait liquide de stillingie, Fr.; *Flüssiges Stillingia-Extrakt*, G.

Preparation.—Take of Stillingia in fine powder sixteen troyounces; Glycerin four fluidounces; Alcohol, Water, each a sufficient quantity. Mix twelve fluidounces of alcohol, three fluidounces of glycerin, and one fluidounce of water, and, having moistened the stillingia with four fluidounces of the mixture, proceed according to directions given in the general formula at page 585. Finish the percolation with diluted alcohol, and, having reserved fourteen fluidounces, add one fluidounce of glycerin to the remainder of the percolate, before evapotion. *U. S.*

This fluid extract is of a dark-brown color, and has the bitterish, pungent taste of the root.

Medical Uses.—It may be employed in various chronic diseases, and especially scrofula, diseases of the skin, syphilis, etc. *Dose*, a fluidrachm.

EXTRACTUM TARAXACI FLUIDUM, *U. S.*—FLUID EXTRACT OF TARAXACUM.

Extrait liquide de pissenlit, Fr.; *Flüssiges Löwenzahn-Extrakt*, G.

Preparation.—Take of Dandelion in moderately fine powder sixteen troyounces; Glycerin four fluidounces; Alcohol, Water, each a sufficient quantity. Mix half a pint of alcohol, three fluidounces of glycerin, and five fluidounces of water, and, having moistened the dandelion with four fluidounces of the mixture, proceed according to directions given in the general formula at page 585. Finish the percolation with diluted alcohol, and, having reserved fourteen fluidounces, add one fluidounce of glycerin to the remainder of the percolate, before evaporation. *U. S.*

Prepared from good dandelion root, the fluid extract is an efficient preparation, of a reddish-brown color, and bitterish, sweet taste. We have seen commercial fluid extracts bearing this name, which, to judge from their appearance and their more decided bitterness, were evidently made from chickory root.

Medical Uses.—It is a more permanent preparation than the decoction of dandelion, and at the same time quite as operative. *Dose*, one or more fluidrachms.

EXTRACTUM UVÆ URSI FLUIDUM, *U. S.*—FLUID EXTRACT OF UVA URSI.

Extrait liquide de busserole, Fr.; *Flüssiges Bärentraubenblätter-Extrakt*, G.

Preparation.—Take of Uva Ursi in moderately fine powder sixteen troyounces; Glycerin four fluidounces; Alcohol, Water, each a sufficient quantity. Mix half a pint of alcohol, three fluidounces of glycerin, and five fluidounces of water, and, having moistened the uva ursi with half a pint of the mixture, proceed according to directions given in the general formula at page 585. Finish the percolation with diluted alcohol, and, having reserved fourteen fluidounces, add one fluidounce of glycerin to the remainder of the percolate, before evaporation. *U. S.*

The process yields a good fluid extract of a dark-brown color, and of the bitter and astringent taste of the leaves, and it contains about 37 per cent. of alcohol.

Medical Uses.—It probably contains all the virtues of the plant. Like nearly all medicines intended to act upon the urinary organs, it should be given largely diluted. *Dose*, a fluidrachm.

EXTRACTUM VALERIANÆ FLUIDUM, *U. S.*—FLUID EXTRACT OF VALERIAN.

Extrait liquide de valériane, Fr.; *Flüssiges Baldrian-Extrakt*, G.

Preparation.—Take of Valerian in fine powder sixteen troyounces; Stronger Alcohol a sufficient quantity. Moisten the valerian with five fluidounces of stronger alcohol, and proceed according to directions given in the general formula at page 585. *U. S.*

Stronger alcohol is well adapted for exhausting the volatile, bitter, and resinous principles of the root, and, if the percolation and evaporation of the weak tincture have been well managed, but little loss of volatile oil will occur.

Medical Uses.—An efficient preparation of this valuable drug. *Dose*, one fluidrachm.

EXTRACTUM VERATRI VIRIDIS FLUIDUM, *U. S.*—FLUID EXTRACT OF AMERICAN HELLEBORE.

Extrait liquide de vératre américain, Fr.; *Flüssiges Grüngermerwurz-Extrakt*, G.

Preparation.—Take of American Hellebore in fine powder sixteen troy-ounces; Stronger Alcohol a sufficient quantity. Moisten the hellebore with five fluidounces of stronger alcohol, and proceed according to directions given in the general formula at page 585. *U. S.*

The resins and alkaloids are readily taken up and held in solution by the menstruum directed, and the fluid extract is therefore of about double the strength of the tincture of the same drug.

Medical Uses.—This preparation is a very potent depressor of the heart's action. *Dose*, one to three minims.

EXTRACTUM ZINGIBERIS FLUIDUM, *U. S.*—FLUID EXTRACT OF GINGER.

Extrait liquide de gingembre, Fr.; *Flüssiges Ingwer-Extrakt*, G.

Preparation.—Take of Ginger in moderately fine powder sixteen troy-ounces; Alcohol a sufficient quantity. Moisten the ginger with four fluidounces of alcohol, and proceed according to directions given in the general formula at page 585. *U. S.*

Ginger is readily exhausted by alcohol; the fluid extract is four times stronger than the tincture of ginger, and has the same sensible properties, but in a higher degree. It is used in preparing Syrupus zingiberis. *U. S.*

Medical Uses.—It is a convenient substitute for the tincture, on account of its greater strength, and for the infusion on account of its small bulk. *Dose*, ten or more minims.

FARINA TRITICI, *Br.*—WHEATEN FLOUR.

Farine de froment, Fr.; *Weizenmehl*, G.

The grain of wheat, Triticum vulgare, *Villars*, ground and sifted.

Nat. Ord.—Graminaceæ.

Origin.—An annual or biennial herbaceous plant, which is probably indigenous to Central Asia, but has been under cultivation from a very early period, and is at present raised in most countries of the temperate zones. The smooth jointed stem (culm) is 3 to 5 feet high; the leaves are long, linear, somewhat rough; the terminal spikes are 3 to 4 inches long, with a flat and finely hairy axis (rachis), and 4 or 5 flowered, flattened spikelets, producing usually three fruits, which are oval-oblong, obtuse, grooved on the upper side, and of a yellowish or brownish color. Numerous varieties have been produced by cultivation, some having the chaff awnless, or the lower paleæ long-awned, and the fruit of a white or reddish color. Spring or summer wheat (*Tr. æstivum*) is awned or bearded; the winter wheat (*Tr. hybernum*) nearly awnless.

Of other species of wheat which are cultivated, the following may be mentioned: *Trit. turgidum*, Lin., of which *Tr. compositum*, or Egyptian wheat, is a variety with compound spikes; *Tr. durum*, Desf., or horny wheat, with long awns, including the varieties *villosum*, *hordeiforme*, and others; *Tr. spelta*, Lin., or spelt, with triangular ovate and obtuse grains, which are little mealy; and *Tr. monococcum*, Lin., or one-grained wheat, with small spikes, and three flowers in each spikelet, two being barren, the third one producing a somewhat triangular grain.

Wheat grain, like the similar graminaceous fruits, has the integuments of the fruit and seed united; underneath this covering is a layer of cells containing *gluten*, and then follows the cellular tissue of the so-called albumen or perisperm, this being filled with numerous *starch* granules. Wheat is most generally prepared for food by grinding, and separating, by means of sieves, the broken integuments, or *bran*, from the fine amylaceous white portion, or *flour*.

Description.—Wheaten flower is a very fine white powder, without odor, and of an insipid taste. The starch granules, which largely compose it, have been described on page 169.

Composition.—Air-dry wheat contains, according to Millon (1854), 12 to 17 per cent. of water, 8 to 16 per cent. of gluten, about 2 per cent. of fat, about 2 per cent. of cellulose, and 1½ to 2 per cent. of ash. Older analyses of different kinds of wheat were principally made by A. Vogel (1818), Proust (1820), Henry and Vauquelin (1822). The amount of starch varies between about 60 and 70 per cent., and the weight of nitrogen between 1.6 and 2.7 per cent. A small quantity of saccharine matter is also present, and the ash contains nearly 50 per cent. of phosphoric acid. The inorganic constituents are mostly found in the bran, to the extent of over 7 per cent., while the nitrogenated principles enter chiefly the flour. If the latter is kneaded with cold water as long as the liquid becomes milky, a yellowish-gray elastic and glutinous mass remains, which is the *gluten* of Beccaria, retains about 70 per cent. of water, and consists, according to Von Bibra, in the dry state of about 70 per cent. *vegetable fibrin*, 3.8 to 9.3 *vegetable casein*, 7.5 to 19.5 *glutin*, and 4.6 to 8.2 per cent. of fat. When fresh it dissolves in dilute phosphoric acid and a solution of potassa. On drying it assumes a hornlike appearance, and partly loses its solubility. According to Boussingault, it contains 15 per cent. of nitrogen.

To purify it Ritthausen (1862–1867) dissolves it in cold very dilute potassa solution (1 to 1000 parts of water), decants from the undissolved starch, and precipitates with acetic acid. The precipitate is repeatedly treated with fresh portions of alcohol, commencing with spec. gr. .914, and increasing the strength finally to absolute alcohol. After another washing with ether, the insoluble portion constitutes *gluten-casein*, which is slightly soluble in acetic acid, freely soluble in potassa, and becomes insoluble by heat. On evaporating the united alcoholic liquids to one-half, and cooling, *gluten-fibrin* is separated, which is freed from adhering casein by dissolving it repeatedly in 60 and 70 per cent. alcohol. It is freely soluble in dilute acetic acid, and when boiled with water, in which it is insoluble, it is converted into a jelly. After the separation of gluten-fibrin, the greater portion of the alcohol is evaporated, the precipitate appearing on cooling is treated with a little alcohol, washed with ether, dissolved in little 65 per cent. alcohol, and precipitated by absolute alcohol. The precipitate is *mucedin*, the solution contains *glutin* or *gliadin*. The former yields with cold or boiling water a milklike liquid; the latter is soluble in water, alcohol, acetic acid, potassa, etc., the aqueous solution being precipitated by the salts of the heavier metals; glutin contains sulphur and 18 per cent. of nitrogen. These principles are the most important ones of the *vegetable protein compounds*.

Off. Prep.—Cataplasma fermenti, *Br.*

Medical Uses.—Wheaten flour is often used as a dusting powder to allay the heat and pain of local inflammations, such as superficial *burns* and *scalds*, *erysipelas*, *erythema*, *intertrigo*, *prickly heat*, etc. But it is very far inferior, for such purposes, to powdered starch. Its dietetic uses need not here be considered, but one among them, which is also partly medicinal, is worthy of notice. It is the administration of an uncooked paste made from wheaten flour in many cases of *diarrhœa*, and especially in those depending upon debility. The summer diarrhœas of this climate are usually curable by this simple remedy, if the patient rests and abstains from other food.

FEL BOVINUM PURIFICATUM, *Br.*—PURIFIED OX-BILE.

Fel tauri depuratum, P. G.; *Fel bovis purificatum*, *Extractum fellis bovini.*—*Purified ox-gall*, E.; *Fiel* (*Bile*) *de bœuf purifié*, Fr.; *Gereinigte Ochsengalle* (*Rindsgalle*), G.

The purified gall of the ox, Bos taurus, *Linn.*

Origin.—Bile is a greenish or brownish, viscid, transparent liquid, which is separated by the liver in the gall-bladder; it has a peculiar odor, becoming prominent on heating; a nauseous, sweet, and bitter taste, a specific gravity of about 1.02, a slight alkaline reaction, and dissolves completely with water. When mixed with its own weight, or twice its bulk of alcohol, a precipitate is produced consisting almost exclusively of mucilaginous matter, and the liquid filtered from it and evaporated constitutes the purified ox-gall of the British Pharmacopœia. The yield is about 10 per cent. The use of copper vessels should be avoided.

Preparation.—Take of Fresh Ox-Bile one pint; Rectified Spirit two pints. Mix the bile and the spirit by agitation in a bottle, and set aside for twelve hours until the sediment subsides. Decant the clear solution, and evaporate it in a porcelain dish by the heat of a water-bath, until it acquires a suitable consistence for forming pills. *Br.*

Properties.—It is a deep yellowish-green extract-like mass, having the peculiar taste of bile, and being completely soluble in water and in spirit, whereby it is distinguished from crude inspissated gall, which does not yield a complete solution with alcoholic liquids.

The German Pharmacopœia directs a still purer article, from which, besides the mucilage, the biliary coloring matters also have been removed; the decolorization is effected after the removal of the mucilage, by distilling off the alcohol and then adding to the residue recently purified and well-washed still moist animal charcoal; 8 to 10 parts of it will be sufficient for 100 parts of bile. The mixture is occasionally agitated, and when the liquid shows only a slight yellow color it is passed through a moistened filter, evaporated in a porcelain capsule by means of a water-bath, and then completely exsiccated in a drying closet or by means of a sand-bath, the heat of which must not be allowed to rise above 100° C. (212° F.). The mass is then reduced to powder and preserved in small well-corked vials. The yield is nearly 7 per cent. It forms a yellowish or yellowish-white powder, which attracts moisture from the atmosphere, and dissolves completely in water and alcohol, the solutions being of a yellowish color and of the sweet and bitter taste of bile. When heated to redness it burns, leaving a small amount of a white alkaline ash. This preparation is sometimes sold as *Choleate* or *Choleinate of sodium.*

Constituents.—The principal coloring matter of bile appears to be *bilirubin*, formerly called *colepyrrhin*, $C_{16}H_{18}N_2O_3$, which is slightly soluble in alcohol and ether, but dissolves in chloroform, bisulphide of carbon, and benzol;

it forms an amorphous or crystalline orange-colored or red powder. It is accompanied by *bilifuscin*, a dark olive-brown powder, soluble in alcohol and in hot chloroform; *biliprasin*, a green-black powder, insoluble in chloroform, soluble in alcohol, with a green, or, in the presence of ammonia, with a brown color; and *bilihumin*, a blackish powder, insoluble in simple solvents, and often found in biliary concretions. *Biliverdin* is formed by the oxidation of bilirubin, is a dark-green powder, soluble in alcohol with a green color, and insoluble in water, ether, and chloroform (Städeler, 1864). The fatty matter of bile is chiefly *cholesterin*, $C_{26}H_{44}O$, which is also an ingredient of the brain, the nerves, the yolk of eggs, etc. It crystallizes in colorless laminæ or prisms, is unchanged by boiling potassa, dissolves in ether, chloroform, and hot alcohol, and is chemically a monatomic alcohol. Ox-gall contains the sodium salts of two peculiar acids, named *glycocholic* (the *cholic acid* of some older authors) and *taurocholic* (Strecker's *choleic*) *acid*, a part of the former of which, together with the remaining pigments, is precipitated by neutral acetate of lead from fresh bile, previously decolorized by animal charcoal. When to the filtrate from this precipitate subacetate of lead is carefully added, until the insoluble compound formed has a white color, the precipitate will consist of glycocholeate and taurocholeate of lead, and the filtrate contains only taurocholic acid, which is precipitated on the further addition of basic acetate of lead. Glycocholic acid, $C_{26}H_{43}NO_6$, is in very fine white needles, of a silky lustre and a sweetish bitter taste. Its salts have a sweet taste, and are mostly soluble in water and alcohol. Boiled with alkalies, it takes up one molecule of water and splits into *glycocol* (*glycin* or *amidoacetic acid*), $C_2H_5NO_2$, and *cholic acid* (*cholalic acid* of Strecker), which has a bitter and afterwards sweetish taste. *Taurocholic acid*, $C_{26}H_{45}NSO_7$, is in silky acicular crystals, easily soluble in water and alcohol, and when boiled with alkalies decomposed into *cholic acid* and *taurin* (*amido-isethionic acid*), $C_2H_7NSO_3$.

Ox-bile contains the two biliary acids in nearly equal proportion; human bile mainly taurocholic acid, which is found in dog-bile almost to the exclusion of other acids. Both acids, dissolved in water and mixed with a little syrup and afterwards with oil of vitriol, acquire a red color, changing to carmine, purple, and violet (*Pettenkofer's test for bile*). Cholic acid shows a similar behavior, and the coloration is also obtained with unpurified bile.

Physiological Action.—The function of the bile is far from being thoroughly understood, for its composition is exceedingly complex, but, along with the pancreatic juice, this secretion seems intended to neutralize the acidity of the chyme as it is received by the duodenum from the stomach, and at the same time to emulsify the fatty matters which the acid secretions of the stomach are not fitted to prepare for absorption. It is further probable that the excess of bile not so employed tends to quicken the peristaltic movements of the bowels. It is at least pretty certain that when the bile is profusely secreted it occasions diarrhœa. It is quite certain that, in doses of from half an ounce to an ounce, fresh ox-bile acts as a laxative, and that if its use be persisted in it is very apt to excite a burning sensation in the rectum, and to induce hemorrhoids. On the other hand it is a familiar fact that when from any cause bile enters the stomach from the intestine, it occasions loss of appetite, nausea, and even vomiting, for the reason, doubtless, that it neutralizes the acidity of the gastric juice which during healthy digestion is always strongly acid. In this way probably it may impair or wholly prevent the gastric digestion of starchy food. There is no physiological probability, nor any clinical evidence to show, that bile, however introduced into the stomach, can promote in any way the digestion of food in that organ. That when administered medicinally it may, on reaching the duodenum, reinforce the action of the bile secreted there, is indeed probable. When the latter secretion, therefore, is deficient, it may tend to prevent the fermentative and putrefactive decomposition of the food, aid in the solution of its fatty constituents, promote the peristaltic action of the intestine, and, in a sufficient dose, provoke purgation.

Medical Uses.—Ox-gall (or pig-gall, which is supposed to be more analogous to human bile) is thought to be an efficient remedy for habitual *constipation* depending upon atony of the intestine. After its use the bowel is not so apt to become torpid as after the use of ordinary purgatives. It is, perhaps, of some interest to note that the medicine which most nearly resembles it in this respect is aloes, which, like bile, is very bitter and tends to irritate the rectum. The *dyspeptic* derangements which are apt to attend constipation, and which often depend upon a distended colon compressing the liver or its ducts, usually subside under purgation of any kind. It is very doubtful if ox-gall exhibits any of the special virtues which have been attributed to it under these circumstances. In *jaundice* depending upon catarrh of the bile-ducts, this medicine is sometimes found advantageous, probably in virtue both of its purgative operation and of its supplying for duodenal digestion the agent which the liver fails to secrete. The objection to its use, that it will be absorbed into the blood already overcharged with bile, is more specious than sound. Bile has been used as a *vermifuge* for lumbricoid ascarides. As a topical remedy it has been applied with alleged success to the treatment of various *glandular* hypertrophies and indurations; but the method has not been accepted.

The administration of bile in a liquid state is too disgusting to be recommended. It may be given in the form of inspissated bile, as directed to be prepared by the British Pharmacopœia. Five grains of this preparation are estimated to be equal to one hundred grains of fresh bile. It may be made into pills coated with gelatin, or inclosed in gelatin capsules. If taken after meals, this coating delays the escape of the bile until the food is ready to pass into the pylorus. About ten grains may be given at a dose.

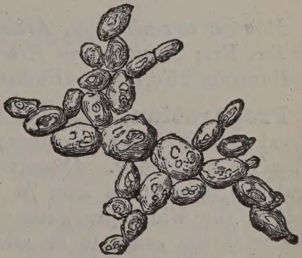
FERMENTUM, *U. S.*—YEAST.

Cerevisiæ fermentum, *Br.*—*Beer yeast*, E.; *Levûre de bière*, Fr.; *Bierhefe*, G.

The ferment obtained in brewing beer.

Origin and Description.—It has been previously stated (see *Alcohol*, p. 119) that alcoholic fermentation depends upon the development of a minute fungoid vegetable, *Torula cerevisiæ*, Turpin, which has also been named *Mycoderma cerevisiæ*, Desmaz., *Saccharomyces vini et cerevisiæ*, Schwann and Meyen, and *Cryptococcus fermentum*, Kützing. This constitutes principally the *brewer's yeast*, of which there are two varieties, the *upper* or *top yeast* (Oberhefe of the Germans), and the *lower* or *bottom yeast* (Unterhefe, *Germ.*). The former is the kind most generally met with in the United States, and is a viscid, semifluid, frothy mass, containing large more or less globular microscopic cells from which smaller ones are developed; it appears upon the surface of the fermenting liquid, and is reproduced therein at a temperature ranging between about 15° and 20° C. (59° and 68° F.). But wort fermented with top yeast at a temperature near or below 10° C. (50° F.) will produce both top and bottom yeast, the latter being solely reproduced by the fermentation from below (Untergährung, *Germ.*) at a temperature of about 9° C. (48° F.) and less. It consists of various sized cells differing from those of the top yeast in not having any small cells attached, and appears to be reproduced from isolated spores, while the

Fig. 71.



Yeast Cells.

other variety multiplies by budding. The cell membrane consists of a kind of cellulose, and the contents of a protein compound analogous to albumen.

When heated to the boiling point of water the yeast plant is killed; but, after expressing from it the water, it may be kept in the dry state without losing its vitality, and forms the *dry yeast* of commerce. *Vienna yeast* is the same article, and is stated by Dr. Vigla (1871) to be made by fermenting a wort obtained from a mixture of maize and rye with barley malt, skimming off the froth, draining and subjecting it to pressure. So-called *artificial* or *patent yeast* is either made of flour dough, with the addition of a little yeast, or of an infusion of hops to which malt is subsequently added. The existence in hops of a ferment, as asserted by Sacc (1875), was denied by Soxlet and Pasteur (1876), who proved that the only effect of hops, when used as stated above, is to impart some bitterness to the mass and somewhat delay the spoiling of the product.

When yeast is added to a solution of pure sugar, active fermentation takes place, the yeast being gradually rendered inert; but in the presence of albuminous matters in the saccharine liquid, the yeast plant is continually reproduced and augmented.

Some investigators have assumed the presence in yeast of a peculiar fermenting principle, *invertin*, which is prepared by Barth (1878), by expressing the water from yeast, drying it completely, heating for 6 hours to between 100° and 105° C. (212° and 221° F.), macerating with water at 40° C. (122° F.), and pouring the filtrate into six times its bulk of alcohol. The precipitate consists of the ferment and albumen, of which the latter is rendered insoluble by prolonged treatment with strong alcohol. Invertin is then dissolved by water, the solution precipitated by alcohol, and the precipitate dried, when it constitutes a brown horn-like mass, which is reduced to powder with difficulty.

Medical Action and Uses.—Yeast is generally described as nutritive and antiseptic. The former it can be only in a slight degree, from the fermented malt liquor which may be mixed with it. It is antiseptic through the carbonic acid which it evolves. There is no doubt that it has appeared to be serviceable in the *typhoid states* of febrile diseases, and that it really is so when applied as a dressing to *gangrenous* and *phagadenic sores*, whose fetor it corrects while it stimulates the nutritive processes in the affected tissues. That its action is a stimulant one is shown by the pain it sometimes causes, and by its popular use in the treatment of recent *bruises*. Through its carbonic acid it must also be anodyne. The power of yeast to convert starch directly into alcohol has been invoked in the treatment of *diabetes*, and in some cases has caused the entire disappearance of sugar from the urine. Some of the patients showed signs of alcoholic intoxication while undergoing this treatment. The yeast may be given in doses of two tablespoonfuls immediately before meals. It has also been used in *scurvy*.

FERRI ARSENIAS, *Br.*—ARSENIATE OF IRON.

Ferrum arsenicicum, Arsenias ferrosus.—Ferrous arseniate, E.; *Arséniate de fer*, Fr.; *Arsensaures Eisen*, G.

Formula $2Fe_3As_2O_8.4FeAsO_4.Fe_2O_3.32H_2O$. Molecular weight 2428.

Preparation.—Take of Sulphate of Iron nine ounces; Arseniate of Soda dried at 300° F. four ounces; Acetate of Soda three ounces; Boiling Distilled Water a sufficiency. Dissolve the arseniate and acetate of soda in two pints, and the sulphate of iron in three pints of the water, mix the two solutions, collect the white precipitate which forms, on a calico filter, and wash until the washings cease to be affected by a dilute solution of chloride of barium. Squeeze the washed precipitate between folds of strong linen in a screw press, and dry it on porous bricks in a warm air-chamber, whose temperature shall not exceed 100° F. *Br.*

On mixing solutions of ferrous sulphate and the officinal disodium arseniate, a white precipitate takes place, which is a mixture of ferrous arseniate ($Fe_3As_2O_8$), and ferrous hydrarseniate ($Fe_2H_4As_2O_8$). In the presence of sodium acetate, however, only the former is precipitated, and free acetic acid is found in the liquid besides sulphate of sodium. The reaction occurs as follows: $3FeSO_4 + 2Na_2HAsO_4 + 2NaC_2H_3O_2 = Fe_3As_2O_8 + 2HC_2H_3O_2 + 3Na_2SO_4$. The white precipitate is very bulky, and while being washed to free it from the mother-liquor and dried, it is oxidized and converted into ferroso-ferric arseniate of the formula given above. The change is indicated by the gradual disappearance of the white color until the salt finally becomes blue-green. In the reaction and final result the process corresponds nearly with the one for the officinal phosphate of iron.

Properties.—Arseniate of iron is a green or blue-green amorphous powder, insoluble in water and alcohol, but dissolving readily in dilute muriatic acid, yielding a bright yellow solution, in which blue precipitates are produced with both ferrocyanide and ferridcyanide of potassium, and which yields with sulphuretted hydrogen first a milkiness (sulphur) and afterwards a yellow precipitate of sulphide of arsenic. It contains nearly 24 per cent. of water, most of which is expelled when heated to 100° C. (212° F.). If the heat is increased a crystalline sublimate of arsenious acid is obtained. It may be distinguished from phosphate of iron, which resembles it in appearance, by boiling a small portion with an excess of caustic soda, filtering and neutralizing exactly with nitric acid, when a brick-red precipitate of arseniate of silver will be produced on the addition of silver nitrate. Phosphate of iron, similarly treated, yields a yellow precipitate. To determine the amount of ferrous salt, which theoretically corresponds to 17.94 per cent. of ferrous oxide, the British Pharmacopœia directs the dissolving of 20 grains in an excess of diluted hydrochloric acid, and adding thereto, gradually, volumetric solution of bichromate of potash, until a drop of the acid solution ceases to give a blue precipitate with potassium ferridcyanide; at least 170 grain measures of the test solution are required for the purpose, indicating 18 per cent. of FeO.

Medical Action and Uses.—It is difficult to conjecture on what grounds this compound was made officinal, since the proportion of iron contained in $\frac{1}{16}$ gr., the dose of it recommended, is too inconsiderable to have any curative action. Iron and arsenic are, both of them, medicines the dose of which must vary greatly and frequently with the nature of the disease and the special condition of the patient, and it is to be preferred that they should be given separately. To any liquid preparation of iron the solution of potassium arsenite may be added at the time of administration. The arseniate of iron is recommended to be given in a pill and in the *dose* of one-twentieth of a grain, gradually increased to half a grain.

FERRI BROMIDUM.—Bromide of Iron.

Brômure ferreux, Fr.; *Eisenbromür*, G.

Formula $FeBr_2$. Molecular weight 216.

Preparation and Properties.—It is prepared by gradually adding 2 parts of bromine to 1 part of iron filings or wire, contained under water, and digesting until the liquid has a greenish color, when it is filtered and evaporated in an iron dish to dryness. It forms a grayish-black mass which, on exposure to air, acquires a brown color through oxidation. On being heated to redness in contact with the atmosphere, it is converted into ferric oxide and ferric bromide, the latter subliming in yellow scales. An aqueous solution of bromide of iron, preserved by sugar, has been proposed as a convenient preparation. W. S. Thompson (1870) gives the following formula for *syrup. ferri bromidi:*—

To 5 fluidounces of water, contained in a pint flask, add 540 grains of bromine, and 270 grains of card teeth, the latter in small quantities, so as to prevent violent reaction, digest until the color has changed to green, filter into a bottle containing 10 troyounces of sugar, and wash the filter with water to make a pint of syrup. A fluidrachm contains rather more than 5½ grains of ferrous bromide.

Physiological Action and Medical Uses.—Five grains of this substance dissolved in two drachms of water and injected into a dog's jugular vein, occasioned dilated pupils, spasmodic twitching, and death in ten minutes; ten grains introduced in the same manner produced general tetanic spasm, in which the animal died. In both cases the veins were engorged, the heart was distended with coagula, and its irritability was very faint. Half a drachm thrown into the stomach brought on violent vomiting, dilatation of the pupils, rapid pulse and respiration, and diarrhœa with dark stools. Signs of inflammation were found in the lungs and stomach.

It is somewhat singular that two agents so physiologically antagonistic as iron and bromine should have been united in the same medicine, since the one tends to produce what the other is employed to subdue. Practically, however, the bromine of the compound is its only active element, as may be inferred from the experiments just related. This preparation has been recommended as an energetic astringent and anti-strumous medicine, and has been prescribed in hypertrophy of the heart and uterus, for scrofulous glandular swellings, both topically and internally, in leucorrhœa, hysteria, and pulmonary phthisis. There is not the slightest evidence of its ever having been useful as a medicine; and, as it is dangerously poisonous, it ought never to be used internally.

FERRI CARBONAS SACCHARATA, *Br.*—SACCHARATED CARBONATE OF IRON.

Ferrum carbonicum saccharatum, P. G.; *Carbonas ferrosus saccharatus.*—*Saccharure de proto-carbonate de fer* (*de carbonate ferreux*), Fr.; *Zuckerhaltiges Kohlensaures Eisen*, G.

Formula of the carbonate $FeCO_3.H_2O$. Molecular weight 134.

The mixture of ferrous carbonate with sugar contains 37 per cent. (20 per cent., *P. G.*) of carbonate of iron, *Br.*

Preparation.—Take of Sulphate of Iron two ounces; Carbonate of Ammonia one and a quarter ounce; Boiling Distilled Water two gallons; Refined Sugar one ounce. Dissolve the sulphate of iron and the carbonate of ammonia each in half a gallon of the water, and mix the two solutions with brisk stirring in a deep cylindrical vessel, which is then to be covered as accurately as possible. Set the mixture by for twenty-four hours, and from the precipitate, which has subsided, separate the supernatant solution by a siphon. Pour on the remainder of the water, stir well, and, after subsidence, again remove the clear solution. Collect the resulting carbonate on a calico filter, and, having first subjected it to expression, rub it with the sugar in a porcelain mortar. Finally dry the mixture at a temperature not exceeding 212° F. *Br.*

Ferrous sulphate and ammonium carbonate decompose each other, forming ferrous carbonate and ammonium sulphate, thus: $FeSO_4+(NH_4)_2CO_3=FeCO_3+(NH_4)_2SO_4$. The operation must be performed with the air as much excluded as possible; hence the importance of employing boiling water from which the air has been expelled, of performing the washing by decantation in deep cylindrical and well-covered vessels, and of collecting and expressing the precipitate rapidly; the subsequent addition of the sugar will, in a measure, protect it against oxidation until it has been finally dried.

Properties.—It forms small lumps, or a gray or greenish-gray powder, having a sweet taste like that of sugar, followed by a very feeble chalybeate taste. When heated in contact with the air, it becomes black, evolving the odor of burning sugar, and is finally converted into red-brown ferric oxide. It dissolves with effervescence in dilute hydrochloric acid, and this solution gives a blue precipitate with potassium ferridcyanide (ferrous salt), and should yield not any or but a very slight white precipitate with chloride of barium, indicating only traces of sulphate left behind from the mother liquor. The pure ferrous carbonate represents 53.7 per cent of ferrous oxide; if no oxidation has taken place, the saccharated carbonate will contain 26 per cent. of ferrous oxide, or 48.5 per cent. of ferrous carbonate. The Pharmacopœia, however, requires less, since the solution of 20 grains in an excess of hydrochloric acid must give a blue precipitate with red prussiate of potassium until only 210 grain measures of the volumetric solution of bichromate of potassium have been used, indicating only 37 per cent. of ferrous carbonate, the remainder having been oxidized.

Off. Prep.—Pilula ferri carbonatis, *Br.*

Medical Action and Uses.—There is no essential difference between the medicinal effects of this preparation and of the subcarbonate of iron, U. S. P. It may be given in the *dose* of from five to twenty grains, after meals.

FERRI CHLORIDUM, *U. S.*—CHLORIDE OF IRON.

Ferrum sesquichloratum, P. G.; *Ferrum muriaticum oxydatum, Chloridum vel Chloruretum ferricum, Ferri perchloridum.—Sesquichloride* (*Perchloride*) *of iron, Ferric chloride*, E.; *Perchlorure de fer, Chlorure ferrique*, Fr.; *Eisenchlorid*, G.

Formula $Fe_2Cl_6.12H_2O$. Molecular weight 541.

Preparation.—Take of Iron in the form of wire and cut in pieces two troyounces; Muriatic Acid twelve troyounces; Nitric Acid a troyounce, or a sufficient quantity. Add the iron to eight troyounces of the muriatic acid, contained in a two-pint flask, and apply a gentle heat until the acid is saturated, and effervescence has ceased. Filter the solution, add to it the remainder of the muriatic acid, heat the mixture nearly to the boiling point, in a four-pint porcelain capsule, and add nitric acid in successive portions until red fumes are no longer evolved, and a drop of the liquid ceases to yield a blue precipitate with ferridcyanide of potassium. Transfer the liquid to a smaller capsule, evaporate it by a gentle heat, on a sand-bath, until reduced to eight troyounces and three hundred and sixty grains, and set aside the residue, covered with glass, until it forms a solid, crystalline mass. Lastly, break this into pieces, and keep the fragments in a well-stopped bottle protected from the light. *U. S.*

In making this officinal salt, about 10 or 15 grains more of iron are advantageously used to facilitate the saturation of the 8 troyounces of muriatic acid; the metal in combining with the chlorine of the acid will produce ferrous chloride $FeCl_2$, hydrogen being given off. The liquid should be passed through a paper filter, and the filtrate at once mixed with the remaining hydrochloric acid, to prevent the deposition of ferric oxychloride, which would be formed by the oxidizing influence of the atmospheric air. When the mixture has been heated to near boiling, the nitric acid is poured in small portions down the side of the porcelain capsule, and the mixture continually stirred. The extrication of the red vapors causes the liquid to froth considerably, hence the necessity of using a capsule holding at least three times the measure of the liquid. Diehl (1867) prefers to heat about three-fourths of the nitric acid, and to add to it gradually the hot mixture of ferrous chloride and muriatic acid, afterwards more nitric acid as required ; frothing is avoided by this manipulation. The object of this part of the process is to transform the ferrous into ferric chloride ; the muriatic and nitric acids react upon each other, with the production of chlorine which unites with the ferrous chloride, and of nitric oxide which escapes, water being formed at the same time, according to the equation $6FeCl_2+6HCl+2HNO_3=3Fe_2Cl_6+2NO+4H_2O$. The liquid should now be tested for ferrous salt by placing a drop upon a porcelain plate, and adding a drop of freshly dissolved potassium ferridcyanide. If a blue color or precipitate is produced, a little more nitric acid is required. Should the brown color be merely darkened, the iron has been all oxidized ; but there may be an excess of nitric acid, which is detected by placing a drop of it upon a plate in contact with a little ferrous sulphate, and adding a drop of strong sulphuric acid. The production of a black color indicates the presence of free nitric acid, which cannot be completely removed by boiling, but requires the addition of a little hydrochloric acid and the application of heat to expel the nitric oxide and chlorine formed until no more nitric acid is shown by the test. During this and the subsequent operation the use of iron spatulas or stirrers must be carefully avoided ; only porcelain or glass should be used.

On evaporating a solution of ferric chloride to the crystallizing point, acid vapors containing muriatic acid are given off, and if the heat is raised to the boiling point, ferric chloride is mechanically carried off. The Pharmacopœia endeavors to avoid this by directing a gentle heat for evaporating the liquid. It will, however, be found of advantage to add about one or two drachms of muriatic acid at the beginning of the evaporation. If this acid has been of the officinal strength, about 9½ troyounces of crystallized ferric chloride will be finally obtained. The crystallization may be effected by keeping the capsule in a warm place until the contents solidify ; but the crystals will then be very damp from inclosed moisture. It is by far better to follow the directions of the Pharmacopœia, and evaporate to less than the weight of the expected salt ; on cooling, the mass will now remain liquid, and is set aside loosely covered, to protect it from dust and other impurities, and at the same time to admit the atmosphere, from which it will attract moisture and gradually crystallize. The crystals begin to form as small circular nodules, having a radiated appearance, floating upon the liquid, and increasing in size until the entire liquid forms a solid mass, which adheres firmly to the vessel. By warming it slightly, the mass is readily detached, at once broken into pieces, and put into dry well-stopped bottles.

Properties.—The officinal ferric chloride forms orange-colored, wart-like pieces, which have a crystalline texture, are very deliquescent, and readily and completely soluble in water, alcohol, and ether, yielding yellowish-brown solutions of an acid reaction, and a strongly ferruginous taste. The crystals fuse, according to Ordway, at 35.5° C. (96° F.); at a higher temperature they are partly decomposed and volatilized.

Impurities.—The presence of nitric acid or of ferrous salt is detected as described above; the complete solubility in the menstrua mentioned is generally an indication of the absence of other metallic salts. A solution of the chloride in water should not be precipitated by barium chloride (absence of sulphate), and when precipitated by an excess of ammonia, the filtrate, on evaporation to dryness, should leave only ammonium chloride, which is completely volatilized at a red heat (absence of alkalies, alkaline earths, zinc, etc.). Copper, if present, is detected by the black precipitate formed by the aqueous solution with sulphuretted hydrogen.

Medical Action and Uses.—Chloride of iron is a powerful astringent and hæmostatic. Its chief uses consist of its applications for stanching *hemorrhage*, as in epistaxis, in hæmotopsis (by inhaling an atomized solution), in bleeding from leech-bites, from the jaw after the extraction of teeth, from the tonsils, from ulceration of the neck of the uterus, from the umbilical cord, from the uterus during and subsequent to abortion, from fungous tumors of various parts, etc. It has also been used in the form of a solution containing one part of "liquor ferri perchloridi fortior," B. P., to three parts of water, and injected into the uterus to control hemorrhage after labor. One pint and a half of the mixture is recommended to be very slowly thrown into the uterus after all clots have been removed. Very many cases in which this method has arrested hemorrhage abruptly are on record, and no doubt can be entertained of its efficacy; but grave apprehensions have arisen respecting its adoption as a general method. It would seem doubtful whether it tends very actively to promote uterine contractions, which must be the chief source of permanent safety in hemorrhage *post-partum*. There is much reason to think that by permitting the retention of coagula in the uterus, a great danger exists of septicæmia from their decomposition. The better opinion seems to be that when such hæmostatics as ergot and ice have failed to arrest the flow, the solution of chloride of iron may be used; but that the clots formed by it should be removed before the products of their decomposition can have had time to affect the system.

Varicose aneurisms have been treated successfully by injections of a solution of chloride of iron; but sudden death having occurred in several instances, the operation can no longer be regarded as warrantable. In regard to other aneurisms, the results have been such that "no prudent surgeon would expose his patient to so disastrous a mode of treatment." It has also been used, apparently without accident, to cure varicose veins, the precaution being taken to compress the vein above and below the puncture.

Chloride of iron, if kept in a bottle, gradually deliquesces, and may be applied with a glass rod or brush. As a hæmostatic, five parts of the chloride may be dissolved in one hundred parts of distilled water, and applied on lint.

FERRI CITRAS, *U. S.*—CITRATE OF IRON.

Ferrum citricum oxydatum, P. G.; *Citras ferricus.—Ferric citrate*, E.; *Citrate de sesquioxyde de fer*, *Citrate ferrique*, Fr.; *Citronensaures Eisenoxyd*, *Eisencitrat*, *G.*

Formula $F_2 2C_6H_5O_7$. Molecular weight 490.

Preparation.—Take of Solution of Citrate of Iron a convenient quantity. Evaporate the solution at a temperature not exceeding 140° F., to the consistence of syrup, and spread it on plates of glass, so that, on drying, the salt may be obtained in scales. *U. S.*

At a higher temperature than indicated by the formula, the salt is slowly reduced to ferrous citrate. When the solution is concentrated to a thick, syrupy liquid, it is spread on plates, and then dried in a dry or warm place. Failure in scaling is usually due to the incomplete saturation of the citric acid with ferric hydrate, occasionally to the presence of saline impurities retained by the negligently washed hydrate.

Properties.—If of the proper composition it readily comes off the plates in the form of thin, garnet-red scales, which yield a red-brown powder. The dry salt was found by Wittstein to yield on ignition 29.5 to 30 per cent. of iron. It is slowly soluble in cold water, more easily and completely in boiling water. It is not precipitated by ammonia, and is not liable to adulteration. The presence of tartaric acid would be detected by acidulating the solution with a few drops of hydrochloric acid, and then adding some potassium acetate, when cream of tartar would be precipitated.

Ammonio-citrate of iron is sometimes sold as *soluble citrate of iron;* it resembles the former in appearance and behavior, except that it is more readily soluble in cold water, gives off the odor of ammonia when heated with an excess of potassa solution, and does not strike a blue color on mixing its solution with potassium ferrocyanide, unless it be acidulated with muriatic acid.

Medical Uses.—It is a mild preparation, and suitable for children and persons of delicate stomach. It should be given in watery solution, and in the *dose* of from five to twenty grains.

FERRI ET AMMONII CITRAS, *U. S.*—CITRATE OF IRON AND AMMONIUM.

Ferri et ammoniæ citras, Br.; *Ferrum citricum ammoniatum*, P. G.; *Ferri ammonio-citras*, *Ferro-ammonium citricum.*—*Ammonio-citrate of iron*, *Soluble citrate of iron*, E.; *Citrate de fer et d'ammoniaque* (*de fer ammoniacal*), *Citrate ferrique ammoniacal*, Fr.; *Citronensaures Eisenoxyd-Ammonium* (*Ammoniak*), G.

Preparation.—Take of Solution of Citrate of Iron a pint; Water of Ammonia six fluidounces. Mix the solution of citrate of iron with the water of ammonia, evaporate the mixture at a temperature not exceeding 140° F. to the consistence of syrup, and spread it on plates of glass, so that, on drying, the salt may be obtained in scales. *U. S.*

Take of Solution of Persulphate of Iron eight fluidounces; Solution of Ammonia nineteen and a half fluidounces; Citric Acid four ounces; Distilled Water a sufficiency. Mix fourteen fluidounces of the solution of ammonia with two pints of distilled water, and to this add gradually the solution of persulphate of iron, previously diluted with two pints of distilled water, stirring them constantly and briskly. Let the mixture stand for two hours, stirring it occasionally; then put it on a calico filter, and, when the liquid has drained away, wash the precipitate with distilled water until that which passes through the filter ceases to give a precipitate with chloride of barium. Dissolve the citric acid in eight ounces of distilled water, and, having applied the heat of a water-bath, add the oxide of iron, previously well drained, and stir them together until the whole or nearly the whole of the oxide has dissolved. Let the solution cool; then add five and a half fluidounces of solution of ammonia. Filter through flannel, evaporate to the consistence of syrup, and dry it in thin layers on flat porcelain or glass plates at a temperature not exceeding 100° F. Remove the dry salt in flakes, and keep it in a stoppered bottle. *Br.*

The second formula requires the preparation of hydrate of iron by decomposing ferric sulphate with ammonia. It is washed and then dissolved in citric acid to obtain a solution of ferric citrate, which, without being filtered, is mixed with ammonia. The turbid liquid at once becomes deeper colored, and is filtered and concentrated. The United States Pharmacopœia, recognizing a solution of ferric citrate, simply requires it to be mixed with ammonia and concentrated.

Properties.—The salt closely resembles citrate of iron in appearance and behavior, except as stated on page 615. Impurities, if present, may be determined in the same manner. The British Pharmacopœia requires it to yield on ignition not less than 27 per cent. of ferric oxide. Being made from normal ferric citrate with the addition of ammonia, it is probably a mixture or compound of ammonio-ferric citrate with ferric oxycitrate. The German Pharmacopœia attempts to obtain a double salt by mixing solutions of ferric citrate and ammonium citrate.

Off. Prep.—Ferri et strychniæ citras, *U. S.;* Vinum ferri citratis, *Br.*

Medical Uses.—The advantages of an iron salt containing ammonia are more than contestable upon theoretical grounds, and there is no evidence of its special value. The addition to a solution of the salt of a solution of citric acid causes effervescence. The *dose* is five or more grains.

FERRI ET AMMONII SULPHAS, *U. S.*—SULPHATE OF IRON AND AMMONIUM.

Ferrum sulfuricum oxydatum ammoniatum, P. G.; *Ferrum ammonio-sulphuricum, Ferri ammonio-sulphas, Sulphas ammonico-ferricus.—Ammonio-ferric alum*, E.; *Sulfate de fer et d'ammoniaque, Sulfate de fer (ferrique) ammoniacal, Alun de fer ammoniacal*, Fr.; *Schwefelsaures Eisenoxyd-Ammonium, Ammoniakalischer Eisenalaun*, G.

Formula $(NH_4)Fe(SO_4)_2.12H_2O$. Molecular weight 482.

Preparation.—Take of Solution of Tersulphate of Iron two pints; Sulphate of Ammonium four troyounces and a half. Heat the solution of tersulphate of iron to the boiling point, add the sulphate of ammonium, stirring until it is dissolved, and set the liquid aside to crystallize. Wash the crystals quickly with very cold water, wrap them in bibulous paper, and dry them in the open air. *U. S.*

On dissolving the ammonium sulphate in the liquid with the aid of heat, a double salt is formed which crystallizes on cooling; the mother liquor will yield another crop of crystals on being concentrated to about one-half. If the solution of ferric sulphate happens to be slightly deficient in acid, the crystals may be of an unsightly appearance; they should then be redissolved in the mother liquor by heat, and a small quantity of sulphuric acid added before crystallizing.

Properties and Tests.—It crystallizes like alum in regular octohedrons, which are colorless or of a pale amethyst or violet color, a strongly astringent taste, and somewhat efflorescent on exposure. At 15° C. (59° F.) the salt requires 3 parts, and at the boiling temperature less than its own weight of water for solution. The aqueous solution has an acid reaction, and shows the chemical reactions of ferric salts, sulphuric acid, and ammonia. Boiled with an excess of potassa solution ammonia is liberated, ferric hydrate is deposited, and the alkaline filtrate neutralized with hydrochloric acid, and again rendered alkaline by ammonia, does not yield a white gelatinous precipitate of aluminium hydrate.

Medical Action and Uses.—Like most of the compounds of sulphuric acid with metals this one is astringent, but its astringency appears to be modified by the ammonia in its composition. It may be advantageously used in chronic *mucous fluxes* of the bowels, vagina, and bronchia, when these affections are prolonged by a general feebleness and relaxation of the tissues. *Dose*, from five to fifteen grains.

FERRI ET AMMONII TARTRAS, *U. S.*—TARTRATE OF IRON AND AMMONIUM.

Ferri ammonio-tartras.—Ammonio-tartrate of iron, E.; *Tartrate de fer et d'ammoniaque, Tartrate ferrique ammoniacal*, Fr.; *Weinsaures Eisenoxyd-Ammonium*, G.

Formula $Fe_2(NH_4)_2 4C_4H_4O_6.5H_2O$. Molecular weight 542.

Preparation.—Take of Tartaric Acid twelve troyounces; Solution of Tersulphate of Iron two pints and a half; Carbonate of Ammonium, Distilled Water, each a sufficient quantity. Dissolve six troyounces of the tartaric acid in two pints of distilled water, and neutralize it carefully by means of carbonate of ammonium; then add the remainder of the acid, dissolved in half a pint of distilled water, and mix the solutions. With the solution of tersulphate of iron, prepare the hydrated oxide of iron according to the formula for that substance, and add it gradually to the solution of bitartrate of ammonium, kept at the temperature of 140° F., until it is no longer dissolved. Then filter the solution, and evaporate, at a temperature not exceeding 140° F., to the consistence of syrup. Lastly, spread it on plates of glass, so that the salt, when it is dry, may be obtained in scales. *U. S.*

This formula is essentially that suggested by Prof. Procter (1841). By neutralizing one-half of the tartaric acid with ammonium carbonate, ammonium tartrate is formed, which is converted into the acid salt by the addition of the reserved tartaric acid. By digesting this with ferric hydrate a solution of the officinal salt is obtained, which, by careful evaporation and drying upon plates, yields it in scales.

Properties and Tests.—It is in transparent garnet-red scales, of a sweetish and slightly ferruginous taste, and yields a rust-colored powder. When heated it gives off water and ammonia, is then charred with the odor of burning sugar, and finally leaves 29 per cent. of ferric oxide, which amount corresponds with the formula given above. It is very probable, however, that compounds of somewhat different composition may be formed by the officinal process. The salt is not soluble in alcohol or ether, but dissolves slowly and freely in glycerin and water. The latter solution is neutral to test-paper, is not precipitated by alkalies or their carbonates, and is not colored blue by potasssium ferrocyanide unless acidulated. When acidulated with muriatic acid and mixed with potassium acetate, cream of tartar is precipitated.

Medical Uses.—The only advantage of this salt is the one it shares with the ammonium salts, viz., that of great solubility. In proportion to its bulk, like them also, it contains but little iron. Its *dose* is from ten to thirty grains.

FERRI ET POTASSII TARTRAS, *U. S.*—TARTRATE OF IRON AND POTASSIUM.

Ferrum tartaratum, Br.; *Tartarus ferratus*, P. G.; *Ferri potassio-tartras, Ferrum tartarizatum, Tartras ferrico-potassicus, s. potassico-ferricus, s. ferrico-kalicus.*—*Tartarated (tartarized) iron, Ferro-tartrate of potassium*, E.; *Tartrate de fer et de potasse, Tartrate ferrico-potassique, Tartre chalybé, Tartre martial*, Fr.; *Weinsaures Eisenoxyd-Kali, Eisenweinstein*, G.

Formula $K_6Fe_2 6C_4H_4O_6$. Molecular weight 1234.

Preparation.—Take of Solution of Tersulphate of Iron a pint; Bitartrate of Potassium seven troyounces; Distilled Water four pints. From the solution of tersulphate of iron prepare the hydrated oxide of iron according to the formula for that substance. Mix the bitartrate of potassium with the distilled water, heat the mixture to 140° F., and keeping it at that temperature, gradually add the hydrated oxide, frequently stirring, until it ceases to be dissolved. Then filter the solution, evaporate it by means of a water-bath, at a temperature not exceeding 140° F., to the consistence of syrup, and spread it upon plates of glass or porcelain, so that when it is dry the salt may be obtained in scales. *U. S.*

The formula of the British Pharmacopœia is like the above, the proportions used being solution of persulphate of iron 5½ fluidounces, solution of ammonia, 10 fluidounces, and acid tartrate of potassium 2 ounces. As in the preceding case, ferric hydrate is first formed, and this is used for saturating the potassium salt. A salt of the above formula is probably first formed, which would yield somewhat over 12 per cent. of ferric oxide; the British Pharmacopœia requires 15; and Soubeiran and Capitaine obtained even 30.8 per cent. of ferric oxide. It is likely that different basic compounds may be formed by prolonged digestion.

Properties.—In its physical properties, as well as in its behavior to solvents, alkalies, and potassium ferrocyanide, it resembles tartrate of iron and ammonium, from which it differs in not giving off ammonia when heated, and, when incinerated, in leaving an ash which has an alkaline reaction to test-paper, and effervesces on the addition of muriatic acid.

TARTARUS FERRATUS, *P. G.*, *s. Ferro-kali tartaricum s. Tartarus martiatus*, is made by digesting 1 part of iron filings and 5 parts of commercial cream of tartar with water until a small portion of it is found to be almost wholly soluble in water when it is dried and powdered. It is a dirty-greenish powder, gradually turning brown, and is almost wholly soluble in 16 parts of cold water. It is a purer potassio-ferrous tartrate, than the *Globuli martiales s. Glob. tartari ferruginosi*, formerly officinal, which preparation, made in the same manner with crude tartar, and formed into balls, with the aid of a little gum-arabic, was known by the name of *steelballs* (*Stahlkugeln*).

Medical Uses.—This salt is one of the richest in iron, the most agreeable to the taste, the least irritating to the bowels and oppressive to the stomach, and the least apt to occasion constipation, of all the soluble ferruginous preparations. *Dose*, from five to twenty grains three times a day, before meals.

FERRI ET QUINIÆ CITRAS, *U. S.*, *Br.*—CITRATE OF IRON AND QUINIA.

Chininum ferro-citricum, P. G.; *Citras ferrico-quinicus.*—*Citrate de fer et de quinine*, Fr.; *Citronensaures Eisen-Chinin*, G.

Preparation.—Take of Solution of Citrate of Iron ten fluidounces; Sulphate of Quinia a troyounce; Diluted Sulphuric Acid, Water of Ammonia, Distilled Water, each a sufficient quantity. Triturate the sulphate of quinia with six fluidounces of distilled water, and, having added sufficient diluted sulphuric acid to dissolve it, cautiously pour in the solution water of ammonia, with constant stirring, until in slight excess. Wash the precipitated quinia on a filter, and, having added it to the solution of citrate of iron, maintained at the temperature of 120° F. by means of a water-bath, stir constantly until it is dissolved. Lastly, evaporate the solution, at a temperature not exceeding 140° F., to the consistence of syrup, and spread it on plates of glass, so that the salt when it is dry may be obtained in scales. *U. S.*

Take of Solution of Persulphate of Iron four and a half fluidounces; Sulphate of Quinia one ounce; Diluted Sulphuric Acid twelve fluidrachms; Citric Acid three ounces; Solution of Ammonia, Distilled Water, of each a sufficiency. Mix eight fluidounces of the solution of ammonia with two pints of distilled water, and to this add the solution of persulphate of iron previously diluted with two pints of distilled water, stirring them constantly and briskly. Let the mixture stand for two hours, stirring it occasionally, then put it on a calico filter, and when the liquid has drained away, wash the precipitate with distilled water until that which passes through the filter ceases to give a precipitate with chloride of barium. Mix the sulphate of quinia with eight ounces of distilled water, add the diluted sulphuric acid, and when the salt is dissolved precipitate the quinia with a slight excess of solution of ammonia. Collect the precipitate on a filter and wash it with a pint and a half of distilled water. Dissolve the citric acid in five ounces of distilled water, and, having applied the heat of a water-bath, add the oxide of iron previously well drained; stir them together, and when the oxide has dissolved, add the precipitated quinia, continuing the agitation until this also has dissolved. Let the solution cool, then add in small quantities at a time twelve fluidrachms of solution of ammonia diluted with two fluidounces of distilled water, stirring the solution briskly, and allowing the quinia which separates with each addition of ammonia to dissolve before the next addition is made. Filter the solution, evaporate it to the consistence of a thin syrup, then dry it in thin layers on flat porcelain or glass plates at a temperature of 100° F. Remove the dry salt in flakes, and keep it in a stoppered bottle. *Br.*

The process of the U. S. Pharmacopœia consists simply in dissolving freshly precipitated quinia in solution of ferric citrate. The apparently complicated process of the British Pharmacopœia is in its first part essentially the same, ferric hydrate and afterwards quinia being dissolved in citric acid; but it differs very materially in the subsequent addition of ammonia and in the formation of ammonium citrate by which the physical properties of the resulting scales are changed.

The corresponding salt of the German Pharmacopœia again differs in containing, besides quinia, both ferric and ferrous salt, but no ammonia; it is made by dissolving powdered iron in citric acid, adding afterwards quinia, evaporating, and scaling.

Properties and Tests.—The product of the first process is in transparent scales, of a yellowish green-brown to reddish-brown color, varying according to their thickness. When heated to redness it leaves a brown ash free from alkaline reaction to test-paper. The salt dissolves slowly in cold, more readily in hot water, and is insoluble in alcohol and ether. The solution is slightly acid to test-paper, has a bitter and chalybeate taste, and yields with ammonia a white precipitate of quinia, with tannin a grayish-black one, consisting of the mixed tannates of iron and quinia, and a blue precipitate with potassium ferrocyanide and some muriatic acid.

The product of the British Pharmacopœia corresponds with the behavior and tests described above, except that it is readily soluble in cold water; it is of a greenish golden-yellow color, and in the air somewhat deliquescent. The Pharmacopœia tests the quality as follows: "Fifty grains dissolved in a fluidounce of water and treated with a slight excess of ammonia give a white precipitate, which, when collected on a filter and dried, weighs eight grains; the precipitate is almost entirely soluble in ether, and when burned leaves but a minute residue." It might be added, that its solution in dilute sulphuric acid shows the characteristic behavior of quinia solutions (see *Quiniæ sulphas*).

Medical Uses.—This preparation has no other demonstrable advantage over an extemporaneous union of the medicines composing it, than arises from the convenience of dispensing it. Five grains of it contain about a grain of quinia, and may be given in pill or solution, before meals.

FERRI ET STRYCHNIÆ CITRAS, *U. S.*—CITRATE OF IRON AND STRYCHNIA.

Citrate de fer et de strychnine, Fr.; *Citronensaures Eisen-Strychnin*, G.

Preparation.—Take of Citrate of Iron and Ammonium five hundred grains; Strychnia, Citric Acid, each five grains; Distilled Water nine fluidrachms. Dissolve the citrate of iron and ammonium in a fluidounce, and the strychnia together with the citric acid in a fluidrachm of the distilled water. Mix the two solutions, evaporate the mixture by means of a water-bath, at a temperature not exceeding 140° F., to the consistence of syrup, and spread it upon plates of glass, so that the salt, when it is dry, may be obtained in scales. *U. S.*

This is simply a mixture of citrate of strychnia with ammonio-ferric citrate, scaled in precisely the same manner as the other iron preparations.

Properties.—It closely resembles ammonio-citrate of iron in appearance, but differs from it in the distinctly bitter taste and in the white precipitate produced by ammonia, the precipitate being soluble in boiling alcohol, from which, if the solution is sufficiently concentrated, crystals will be obtained giving the peculiar reactions of strychnia.

Medical Uses.—This very unnecessary officinal compound may be prescribed in *doses* of one or two grains, and cautiously increased.

FERRI FERROCYANIDUM, *U. S.*—FERROCYANIDE OF IRON.

Ferri ferrocyanuretum, Ferrum ferrocyanatum (s. borussicum s. zooticum), Cyanuretum ferroso-ferricum, Cœruleum borussicum.—Ferrocyanuret of iron, Prussian blue, E.; *Ferrocganure (Prussiate, Cyanure) de fer, Bleu de Prusse (de Berlin)*, Fr.; *Ferrocyaneisen, Berliner Blau*, G.

Formula $Fe_4Fcy_3 = Fe_43Fe(CN)_6.18H_2O$. Molecular weight 1184.

Preparation.—Take of Ferrocyanide of Potassium nine troyounces; Solution of Tersulphate of Iron a pint; Water three pints. Dissolve the ferrocyanide of potassium in two pints of the water, and add the solution gradually to the solution of tersulphate of iron, previously diluted with the remainder of the water, stirring the mixture during the addition. Then filter the liquid, and wash the precipitate on the filter with boiling water until the washings pass nearly tasteless. Lastly, dry it, and rub it into powder. *U. S.*

The process is one of simple decomposition, the basylous radicals exchanging their acids, thus $3K_4Fcy + 2Fe_2(SO_4)_3 = 6K_2SO_4 + Fe_4Fcy_3$. The precipitate requires considerable washing to free it from the potassium salt, and when dried at a temperature of about 40° C. (104° F.), or less, it retains $18H_2O$ in combination, which it gradually loses at a higher temperature.

For uses in the arts, Prussian blue is made by precipitating ferrous sulphate with potassium ferrocyanide, and exposing the bluish-white precipitate to the air, or treating it with oxidizing agents until it has acquired the proper shade; the commoner varieties contain alumina and other impurities.

Properties.—Ferric ferrocyanide is in hard dark-blue masses, which exhibit upon the fresh somewhat conchoidal fracture a reddish lustre, and yield a deep-blue powder. It is tasteless, insoluble in water, alcohol, and dilute mineral acids, but yields, with oxalic acid, equal to one-sixth or upwards of its own weight, a powder which dissolves completely in water, and which has been used as *wash-blue* and *blue ink*. Commercial Prussian blue should be previously purified for this purpose by treating it with dilute muriatic or sulphuric acid, and washing it with water. Concentrated mineral acids decompose it with the liberation of hydrocyanic acid, and, when boiled with alkalies, ferric hydrate is separated and alkaline ferrocyanide dissolved.

Impurities and Adulterations.—On boiling impure Prussian blue with dilute muriatic acid, the presence of carbonates will be indicated by effervescence, and the potassium sulphate, alumina, and ferric hydrate will enter into solution. Ammonia water added to it will precipitate some of these impurities, and the filtrate may be tested for calcium by oxalic acid, or evaporated to dryness and ignited, when no residue should be left. The ammonia, if any, is evolved when boiled with potassa solution, which leaves ferric hydrate behind, and, if alumina should have been present, the clear liquid will yield a white precipitate on being neutralized with muriatic acid, and again rendered alkaline by ammonia. On incinerating Prussian blue, and treating the residue with strong muriatic acid, barium sulphate (heavy spar) will be left undissolved; and the clear acid filtrate, when diluted with water, will yield a black precipitate with sulphuretted hydrogen, should lead or allied metals have been present.

Medical Uses.—The daily *dose* of this preparation is stated by certain authorities to be from half a drachm to five drachms. It is probably inert.

FERRI HYPOPHOSPHIS, *U. S.*—HYPOPHOSPHITE OF IRON.

Ferrum hypophosphorosum, Hypophosphis ferricus.—Hypophosphite de fer, Fr.; *Unterphosphorigsaures Eisenoxyd*, G.

Formula $Fe_2 6PH_2O_2$. Molecular weight 502.

Preparation.—A solution of hypophosphite of sodium, which is free from carbonate, is added to a solution of ferric chloride or ferric sulphate, which should not contain any excess of acid. The precipitate is well washed with distilled water, and dried with a moderate heat. It is a process of double decomposition between the sodium and ferric salts. The presence of carbonate in the former would contaminate the salt with a corresponding quantity of ferric hydrate, while an excess of acid would occasion loss by preventing the ferric hypophosphite from being precipitated.

Properties.—It is a white or grayish powder, nearly tasteless, slightly soluble in water, more so in hypophosphorous acid, but freely so in muriatic acid. It is readily oxidized by nitric acid and other oxidizing agents, and when heated in the dry state evolves inflammable hydrogen phosphide, and leaves ferric pyrophosphate. Its formula is given above; it contains, in addition, water of hydration, the amount of which has not been determined.

Tests.—It should be completely soluble in dilute acetic acid, which leaves white ferric phosphate undissolved. The solution is not precipitated by oxalate of ammonium (absence of calcium salt).

Medical Action.—It is theoretically assumed to possess virtues belonging to phosphorus as well as iron, an assumption which nothing justifies. It may be given in *doses* of five or ten grains.

FERRI IODIDUM, *Br.*—IODIDE OF IRON.

Ferrum iodatum, P. G.; *Ioduretum ferrosum.—Ferrous iodide*, E.; *Iodure de fer, Iodure ferreux*, Fr.; *Eisenjodür, Jodeisen*, G.

Formula FeI_2. Molecular weight 304.

Preparation.—Take of Fine Iron one and a half ounces; Iodine three ounces; Distilled Water fifteen fluidounces. Put the iodine, iron, and twelve ounces of the water into a flask, and having heated the mixture gently for about ten minutes, raise the heat and boil until the froth becomes white. Pass the solution as quickly as possible through a wetted calico filter into a dish of polished iron, washing the filter with the remainder of the water, and boil down until a drop of the solution taken out on the end of an iron wire solidifies on cooling. The liquid should now be poured out on a porcelain dish, and, as soon as it has solidified, should be broken into fragments and inclosed in a well-stoppered bottle. *Br.*

Iodine unites with iron in the presence of water, forming a green solution of ferrous iodide which, on evaporation, is readily oxidized; hence the direction to evaporate in a polished iron dish, which, however, cannot prevent the formation of oxide, or possibly oxy-iodide of iron. The residuary salt is therefore never completely soluble in water.

Properties.—According to De Luca, pure anhydrous ferrous iodide is white and, in the presence of moisture, greenish. The British Pharmacopœia requires it to be green with a tinge of brown. By the officinal process, however, it is usually obtained as a steel-gray laminated mass, with a metallic lustre, fusing at about 177° C. (350° F.) and evolving vapors of iodine. It is deliquescent when pure, dissolves readily with a green color in water, also in glycerin and alcohol, the solution yielding a dark blue precipitate with potassium ferridcyanide, and separating iodine on the addition of a little chlorine water, when on the further addition of mucilage of starch a blue coloration will be produced.

Solid ferrous iodide is, at best, a very unsatisfactory medicinal preparation, owing to the unavoidable changes occurring under ordinary circumstances. It would be better, by far, when ferrous iodide is desired in a solid form, to evaporate a definite quantity of the officinal syrup and convert that at once into pills by the addition of some vegetable powder; or to preserve the solid salt in the manner directed by the German Pharmacopœia for *Ferrum iodatum saccharatum*, by adding to the filtered solution of the ferrous iodide five parts of sugar of milk for each part of iodine employed; then evaporating to dryness and powdering. This yields a yellowish-white powder, which gives a nearly clear solution with 7 parts of water, and contains 20 per cent. of dry ferrous iodide.

Medical Action and Uses.—They are sufficiently described under *Syrupus ferri iodidi*, the only officinal preparation, *U. S. P.*, which contains iodine and iron in combination. The *dose* of this iodide may be stated at from one to three grains three times a day. It should be prescribed in pilular form and taken after meals.

FERRI LACTAS, *U. S.*—Lactate of Iron.

Ferrum lacticum, P. G.; *Lactas ferrosus.*—*Lactate de fer*, Fr.; *Milchsaures Eisenoxydul*, *Eisenlactat*, G.

Formula $Fe2C_3H_5O_3.3H_2O$. Molecular weight 288.

Preparation.—Take of Lactic Acid a fluidounce; Iron in the form of filings half a troyounce; Distilled Water a sufficient quantity. Mix the acid with a pint of distilled water in an iron vessel, add the iron, and digest the mixture on a water-bath, supplying distilled water, from time to time, to preserve the measure. When the action has ceased, filter the solution while hot into a porcelain capsule, and set it aside to crystallize. At the end of forty-eight hours decant the liquid, wash the crystals with a little alcohol, and dry them on bibulous paper. By evaporating the mother-water in an iron vessel to one-half, filtering it while hot, and setting the liquid aside, more crystals may be obtained. *U. S.*

The iron unites directly with the acid, displacing the basylous hydrogen, the solution of ferrous lactate merely requiring to be evaporated and crystallized.

Properties.—It is a greenish-white or yellowish crystalline powder or crusts, having a sweetish and mild chalybeate taste, and containing 19 per cent. of water of crystallization. It is insoluble in cold alcohol, dissolves in 48 parts of water at 10° C. (50° F.), and in 12 parts of boiling water. On the application of heat it turns brown and black, and then, with frothing, emits white acid vapors. In contact with the air the aqueous solution turns speedily brown, forming ferric lactate; the salt boiled for fifteen minutes with an excess of nitric acid, diluted with an equal bulk of water, yields on cooling white granules of mucic acid.

To prepare a purer salt than can be obtained by the officinal process, Pagenstecher (1842) proposed to dissolve an alkaline lactate in alcohol, and to mix this with a concentrated solution of ferrous chloride, when, after a day or two, crystalline crusts are obtained, which are washed with alcohol. Thus prepared it is less prone to oxidation.

Impurities and Adulterations.—The salt is not liable to be contaminated with impurities except ferric salt, the formation of which it is difficult to prevent by the officinal process. Accidental and wilful adulterations are detected, according to the German Pharmacopœia, by adding to the aqueous solution neutral acetate of lead, which should scarcely cause a slight turbidity.

A white precipitate might indicate the presence of hydrochloric, sulphuric, citric, malic, or tartaric acid. When heated with a slight excess of caustic soda and filtered from the precipitate, the nearly cold liquid should not yield a white coagulation on the addition of alcohol (absence of gum) or produce a red precipitate on boiling with a little sulphate of copper (absence of sugars).

Medical Action and Uses.—Lactate of iron has been alleged to be more assimilable than other ferruginous salts, upon the ground that lactic acid is a normal secretion of the stomach. Admitting this ground to be settled, the inference is illogical. Clinically, it may be said that lactate of iron is a very unirritating salt, and that, owing to its feeble flavor, it is taken without repugnance. The statements made of its curative powers are neither more nor less than may be made of other mild salts of iron. It may be given in the dose of one or more grains, in pill or in solution. Owing to its difficult solution in water and its liability to oxidation, it is not readily dispensed in a liquid form; but it may be dissolved in hot syrup to the extent of about four grains to the fluidounce. Locally, attempts have been made to cure *erectile tumors* by injecting them with a solution of "eight grains of lactate of iron to a drachm of distilled water." The statement is incorrect, since the salt requires forty-eight parts of cold water to dissolve it.

FERRI OXALAS, *U. S.*—OXALATE OF IRON.

Ferrum oxalicum, Oxalas ferrosus.—Oxalate de fer, Fr.; *Oxalsaures Eisenoxydul*, G.

Formula $FeC_2O_4.H_2O$. Molecular weight 162.

Preparation.—Take of Sulphate of Iron two troyounces; Oxalic Acid four hundred and thirty-six grains; Distilled Water a sufficient quantity. Dissolve the sulphate of iron in thirty fluidounces, and the oxalic acid in fifteen fluidounces of distilled water. Filter the solutions, and having mixed them with agitation, set aside the mixture until the precipitate is deposited. Decant the clear liquid, wash the precipitate until the washings cease to redden litmus, and dry it with a gentle heat. *U. S.*

On adding a solution of oxalic acid to a solution of a ferrous salt, the acid of the latter is liberated, while the iron unites with the former to ferrous oxalate, which, being almost insoluble, is deposited.

Properties.—It is a pale, almost lemon-yellow, crystalline powder, requiring 4500 parts of cold, and nearly the same quantity of boiling water for solution. It dissolves in cold concentrated muriatic and in hot diluted sulphuric acid, but is scarcely soluble in oxalic acid. Alkalies and their carbonates decompose it, with the formation of alkaline oxalates. When heated to about 155° C. (311° F.) it loses its water of crystallization, and at a higher temperature is completely decomposed, yielding, in contact with the air, 49.3 per cent. (not less than 48, U. S. P.) of ferric oxide. This corresponds with the formula given above, the correctness of which was proved (1861) by H. Croft and E. Reynold. Formerly it was assumed to contain double the amount of water ($2H_2O$).

Medical Uses.—The special therapeutical uses of this preparation are unknown to us. The *dose* is stated to be two or three grains.

FERRI OXIDUM HYDRATUM, *U. S.*—HYDRATED OXIDE OF IRON.

Ferri peroxidum humidum, Br.; *Antidotum arsenici*, P. G.; *Hydras ferricus.—Moist peroxide of iron*, E.; *Sesquioxide (Peroxyde) de fer hydraté humide; Hydrate de peroxyde de fer gélatineux*, Fr.; *Feuchtes Eisenoxydhydrat, Gegengift der Arsenigen Säure*, G.

Preparation.—Take of Solution of Tersulphate of Iron a pint; Water of Ammonia twenty fluidounces; Water a sufficient quantity. To the water of ammonia, mixed with two pints of water, add, stirring it constantly, the solution of tersulphate of iron, previously mixed with two pints of water. Then pour the whole on a wet muslin strainer, and wash the precipitate with water until the washings pass nearly tasteless. Lastly, mix the precipitate with sufficient water to make the mixture measure a pint and a half, and transfer it to a wide-mouthed bottle, which must be well stopped.

When hydrated oxide of iron is to be made in haste for use as an antidote, the washing may be performed more quickly, though less perfectly, by pressing the strainer forcibly with the hands until no more liquid passes, and then mixing the precipitate with sufficient water to make the mixture measure a pint and a half. *U. S.*

Take of Solution of Persulphate of Iron sixty parts; Common Water one hundred and twenty parts. Mix, and add of Calcined Magnesia seven parts, previously triturated, intimately, with Common Water, one hundred and twenty parts; then shake together constantly until a soft homogeneous pulp is produced. *P. G.*

Ferric hydrate is prepared from the solution of the sulphate by decomposing the salt with ammonia (U. S. P.), or with soda (Brit. Ph.), the latter authority ordering four fluidounces of its solution of persulphate after diluting with a pint (imper.) of distilled water, to be gradually poured into 33 fluidounces of soda solution, and to set aside for two hours before straining and washing as directed in the first formula. In the one case ammonium sulphate, in the other sodium sulphate, is formed; salts which are readily soluble in water, and almost completely removed by continued washing with water. The brown ferric hydrate remaining behind has the formula $Fe_2 6HO$ (mol. weight 214). It combines very easily with acids, and for this reason is an effectual antidote to arsenic, which forms with it an insoluble salt. It cannot be dried without losing water, and being converted into oxyhydrate of the formula $Fe_2O_2 2HO$, which combines less readily with acids, and not at all with arsenious acid. This change is prevented by keeping the hydrate, as obtained by the above processes, under water; but after some time it parts with half its water of hydration, forming the reddish-brown ferric oxyhydrate $Fe_2O_3.Fe_2 6HO$, which has lost the power of combining with weak acids, such as arsenious acid. A similar effect may be wholly or partly obtained during the preparation of the hydrate if the mixture is allowed to become hot. Its effectiveness as an antidote is due to two conditions—the making of the hydrate at the *ordinary*, not at an elevated temperature; and its *recent* preparation.

But since the apothecary does not receive previous notice when the antidote will be required, it is best to make it fresh, when needed, by a process which will occupy but a few minutes. This may be accomplished by at once collecting upon a strainer, and expressing as directed by the United States Pharmacopœia; the mixture will then contain some ammonium sulphate and a little ammonia—the latter, however, should be scarcely recognizable by the odor. The same object is attained by the German Pharmacopœia in substituting magnesia for the more caustic ammonia or soda. The magnesia is used in excess, more than is necessary for separating all the ferric hydrate, and the mixture is prevented from becoming heated by triturating the magnesia previously with water. Neither filtration nor straining is requisite, the compounds of the mixture being ferric and magnesium hydrates and magnesium sulphate, none of which has any caustic or otherwise injurious effect, nor forms a soluble compound with arsenic. The solution of tersulphate of iron (*U. S. P.*) is almost identical with that of the German Pharmacopœia, and the same proportions (by weight) may therefore be used in making the antidote; by decreasing the 60 to 55 parts, leaving the other ingredients as directed in the formula, nearly identical preparations are obtained.

Medical Action and Uses.—It is chiefly used as a chemical antidote to arsenic. But although the chemical relations of an arsenical solution may favor the precipitation of its arsenic by freshly prepared hydrated oxide of iron, there is good reason to suppose that in ordinary cases of arsenical poisoning, the greater part of the poison remains in the stomach undissolved, and that the iron, in so far as it is useful, operates chiefly as a mechanical antidote, by enveloping the arsenic, and shielding the stomach until the bulk of the mass or emetics cause its discharge. This statement is inferred from the fact that a very large excess of the oxide is essential to its efficiency.

FERRI OXIDUM MAGNETICUM, *Br.*—MAGNETIC OXIDE OF IRON.

Ferrum oxydatum magneticum, Oxydum ferroso-ferricum.—Black oxide of iron, E.; *Oxide de fer noir (magnétique)*, Fr.; *Magneteisen, Eisenoxyd-Oxydul*, G.

Formula $Fe_3O_4 = FeO.Fe_2O_3$. Molecular weight 232.

Preparation.—Take of Solution of Persulphate of Iron five and one-half fluidounces; Sulphate of Iron two ounces; Solution of Soda four pints; Distilled Water a sufficiency. Dissolve the sulphate of iron in two pints of the water, and add to it the solution of persulphate of iron; then mix this with the solution of soda, stirring them well together. Boil the mixture, let it stand for two hours, stirring it occasionally; then put it on a calico filter until it ceases to give a precipitate with chloride of barium. Lastly, dry the precipitate at a temperature not exceeding 120° F. *Br.*

Magnetic oxide, which is found in Sweden as magnetic iron ore, consists of one molecule each of ferrous and ferric oxides. When solutions of ferrous and ferric salts are mixed in molecular proportions, and then precipitated by a caustic alkali, the same compound is thrown down in a hydrated condition. The mixture should without delay be boiled for some time until the precipitate has become denser and settles readily. It may then without difficulty be washed by decantation, and finally upon the filter without being prone to oxidation as before the boiling.

Properties.—It is a tasteless brownish-black powder, which is strongly attracted by the magnet, and dissolves without effervescence in warm muriatic acid diluted with half its volume of water. This solution yields blue precipitates with both ferrocyanide and ferridcyanide of potassium. When heated in a test-tube it gives off moisture, and when the heat is continued in contact with the air, red ferric oxide is left. Lefort (1852) found magnetic oxide of iron to contain 1 molecule, or 7.2 per cent. of water. According to the British Pharmacopœia, it contains about 20 per cent.

Its purity is ascertained by the tests given and by sulphuretted hydrogen added to the dilute solution in muriatic acid, which should produce only a white turbidity from separated sulphur, but not a black precipitate (absence of copper, etc.). Should it have been insufficiently washed, the alkaline sulphates or chlorides may be detected in the distilled water, shaken with a portion of the oxide.

Under the name of *Æthiops martialis* various old Pharmacopœias recognized black ferroso-ferric oxide, which varied in composition according to the different methods of preparation.

Medical Action and Uses.—This preparation has been but little used of late, owing to the want of uniformity in its composition. It is, however, rich in iron, and may be prescribed in all the cases in which the subcarbonate is employed. The *dose* is from five to ten grains, and should be taken after meals.

FERRI PEROXIDUM HYDRATUM, *Br.*—HYDRATED PEROXIDE OF IRON.

Ferrum oxydatum fuscum, P. G.; *Ferrum hydricum*, *Ferri oxydum rubrum*, *Oxydum ferricum hydratum*, *Ferrugo*, *Rubigo*, *Crocus martis aperiens.*—*Ferric oxide*, E.; *Sesquioxide de fer hydraté*, *Hydrate de susquioxyde de fer sec*, Fr.; *Eisenoxydhydrat*, G.

Formula $Fe_2O_3.H_2O = Fe_2O_32HO$. Molecular weight 178.

Preparation.—The British Pharmacopœia directs this to be prepared by drying the moist peroxide of iron at a temperature not exceeding 100° C. (212° F.).

The process of the German Pharmacopœia is like that for Ferri oxidum hydratum, *U. S.*, the resulting moist oxide being dried at a gentle heat.

This preparation is almost identical with Ferri subcarbonas, *U. S.*, which see.

A so-called oxide of iron soluble in water has been adopted in the German Pharmacopœia under the name of FERRUM OXYDATUM SACCHARATUM SOLUBILE; saccharate of iron, soluble saccharated oxide of iron, *E.;* Saccharure d'oxyde de fer, *Fr.;* Eisenzucker, Lösliches Eisenoxyd, *G.*

The following directions are given for its preparation:—

Take of solution of Ferric Chloride and Simple Syrup each twenty parts; mix them, and add slowly, with constant stirring, Solution of Soda forty parts. After twenty-four hours pour the clear solution into three hundred parts of hot distilled water, decant the liquid from the precipitate, wash it with distilled water first by decantation, afterwards upon a filter, as long as the washings pass off colorless and have a strong alkaline reaction. Strain the precipitate and press it, then add to it ninety parts of sugar and evaporate the mixture in a porcelain capsule by means of a steam bath, and when dry, add sufficient sugar to make the whole weigh one hundred parts.

This is reduced to a reddish powder, which has a sweet and mild chalybeate taste, and is entirely soluble in five parts of distilled water, yielding a deep reddish-brown solution of a feeble alkaline reaction. It contains 3 per cent. of metallic iron.

Medical Action and Uses.—Hydrated peroxide of iron, formerly known as sesquioxide of iron, is not an eligible preparation of the metal, on account of its comparative insolubility and the bulk of it which must be given. Owing to the former quality it blackens the stools, and to the latter it is apt to oppress the stomach. It was at one time largely used in the treatment of *neuralgia* and also of *cancer*, but with little advantage. The *dose* is from ten to thirty grains or more, given in an aromatic syrup.

FERRI PHOSPHAS, *U. S.*, *Br.*—PHOSPHATE OF IRON.

Ferrum phosphoricum, P. G.; *Phosphas ferroso-ferricus.*—*Ferroso-ferric phosphate*, E.; *Phosphate de fer*, *Phosphate ferroso-ferrique*, Fr.; *Phosphorsaures Eisenoxydul* (*Eisenoxydul-Oxyd*), G.

Formula $Fe_3 2PO_4.FePO_4.12H_2O$. Molecular weight 725.

Preparation.—Take of Sulphate of Iron five troyounces; Phosphate of Sodium six troyounces; Water eight pints. Dissolve the salts separately, each in four pints of the water; then mix the solutions, and set aside the mixture until the precipitate has subsided. Lastly, having poured off the supernatant liquid, wash the precipitate with hot water, and dry it with a gentle heat. *U. S.*

Take of Sulphate of Iron three ounces; Phosphate of Soda two and a half ounces; Acetate of Soda one ounce; Boiling Distilled Water four pints. Dissolve the sulphate of iron in one-half of the water, and the phosphate and acetate of soda in the remaining half. Mix the two solutions, and, after careful stirring, transfer the precipitate to a calico filter, and wash it with hot distilled water, till the filtrate ceases to give a precipitate with chloride of barium. Finally dry the precipitate at a temperature not exceeding 120° F. *Br.*

The mineral *vivianit*, which forms pale-blue crystals, is mainly ferrous phosphate. On bringing together solutions of ferrous sulphate and sodium phosphate, a white precipitate of ferrous phosphate is produced, which, on exposure, and during the washing, is oxidized, and acquires a more or less blue, greenish-blue, or grayish-blue color. During the reaction a portion of the sulphuric acid is set free, and retains phosphate of iron in solution, to obtain which the British Pharmacopœia directs the addition of sodium acetate, which, reacting with the free sulphuric acid, forms sodium sulphate and free acetic acid, in which the phosphates of iron are insoluble. The washing of the precipitate must be continued until the filtrate fails to give a reaction for sulphuric acid.

Properties.—It is a tasteless and inodorous bluish powder, varying somewhat in shade. It is insoluble in water, dissolves in hydrochloric acid, yielding a yellow solution in which dark-blue precipitates are produced by both ferro- and ferridcyanide of potassium. If the acid solution is treated with sufficient tartaric acid, and then with an excess of ammonia, no precipitate is produced; but, on the addition of sulphate of magnesium a white precipitate falls. When the powder is boiled with caustic soda, the filtrate, after being neutralized, yields a yellow precipitate with nitrate of silver. Both precipitates indicate phosphoric acid. The chemical composition varies to some extent, and is influenced by its exposure to the atmosphere while moist, the temperature at which it is dried, etc. The above formula is that of Rammelsberg. Wittstein obtained a somewhat different result. The British Pharmacopœia regards it as ferrous phosphate partially oxidated, and requires 20 grains of it dissolved in hydrochloric acid to give a blue precipitate with potassium ferridcyanide, until 250 grain measures of the volumetric solution of potassium bichromate have been added.

Tests.—The salt should yield nothing to hot distilled water (insufficient washing), and the solution in muriatic acid should only yield a white turbidity of sulphur with sulphuretted hydrogen, but not a black (copper, etc.) or a yellow (arsenic) precipitate. The same solution, digested with bright copper, does not form a dark deposit of arsenic upon the metal.

Medical Action and Uses.—Owing to its insolubility in water, this preparation must be given in pill or in powder, of which the last is preferable, in the *dose* of from five to ten grains. It is extremely doubtful whether the phosphoric acid in its composition confers any special virtues upon it.

FERRI PYROPHOSPHAS, *U. S.*—PYROPHOSPHATE OF IRON.

Ferrum pyrophosphoricum cum ammonio citrico, P. G.; *Pyrophosphas fericus cum citrate ammonico.—Pyrophosphate of iron with ammonium citrate*, E.; *Pyrophosphate de fer citro-ammoniacal*, Fr.; *Pyrophosphorsaures Eisenoxyd mit Citronensaurem Ammonium*, G.

Preparation.—Take of Phosphate of Sodium seven troyounces and a half; Solution of Tersulphate of Iron seven fluidounces, or a sufficient quantity; Citric Acid two troyounces; Water of Ammonia five fluidounces and a half, or a sufficient quantity; Water a sufficient quantity. Heat the phosphate of sodium in a porcelain capsule until it undergoes the watery fusion, and continue the heat until it becomes dry. Transfer the dry salt to a shallow iron capsule, and heat it to incipient redness, without fusion. Then dissolve it in three pints of water, with the aid of heat, and, having filtered the solution and cooled it to the temperature of 50° F., add solution of tersulphate of iron until this ceases to produce a precipitate. Stir the mixture thoroughly, and pour it upon a muslin strainer, and, when the precipitate has drained, wash it with water until the washings pass nearly tasteless, and transfer it to a weighed porcelain capsule.

To the citric acid, contained in a suitable vessel, add water of ammonia, until the acid is saturated and dissolved. Then add the solution to the precipitate in the weighed capsule, stir them together, and evaporate until the liquid is reduced to sixteen troyounces. Spread this on plates of glass or porcelain, so that the salt, when it is dry, may be obtained in scales. Lastly, preserve it in a well-stopped bottle, protected from the light. *U. S.*

When sodium phosphate is exsiccated, and afterwards heated almost to redness, it is converted into pyrophosphate, $Na_4P_2O_7$. On precipitating its solution by ferric sulphate, a white precipitate of ferric pyrophosphate, $Fe_43P_2O_7$, is obtained, which, like other insoluble ferric salts, is readily soluble in alkaline citrates, forming green solutions. Ammonium citrate is directed by the Pharmacopœia, the solution being evaporated and the syrupy liquid scaled upon plates.

Properties.—The salt is obtained in transparent apple-green scales, which are freely soluble in water, yielding a greenish solution; this has a slightly saline and mild chalybeate taste, and gives, with potassium ferrocyanide, a blue color, but no precipitate. Exposed to dry air, the scales become opaque, and are then but partly soluble in water, but wholly so on the addition of some ammonia. Excess of ammonia produces no precipitate, but boiling with caustic potassa yields a yellowish-white deposit. The officinal salt represents 48 per cent. of anhydrous ferric pyrophosphate.

Regarding its chemical composition, two views have been entertained. According to the one, it is a double salt of ferric pyrophosphate and ammonium citrate; according to the other, which has been advocated by Rother (1876), it is a mixture of ammonio-ferric pyrophosphate, $Fe_43P_2O_7.3(NH_4)_4P_2O_7$, with ammonio-ferric citrate and ferric citrate. The latter formula corresponds with that of Gladstone for sodio-ferric pyrophosphate, for which Fleitmann and Persoz (1848) give the formula $Fe_43P_2O_7.2Na_4P_2O_7$.

The double salt mentioned has been admitted in the German Pharmacopœia as *Natrum pyrophosphoricum ferratum.* It is directed to be prepared by adding to a solution of 200 parts of sodium pyrophosphate in 400 parts of water so much ferric chloride in aqueous solution that a permanent precipitate is not produced, and mixing with the greenish liquid 1000 parts of alcohol. A white amorphous powder is thus obtained, which dissolves slowly in water, yielding a greenish solution; this, on boiling, separates a white precipitate.

Medical Action and Uses.—The tastelessness, solubility, and richness in iron of this salt, render it one of the best of ferruginous preparations. *Dose*, from two to five grains.

FERRI SUBCARBONAS, *U. S.*—SUBCARBONATE OF IRON.

Crocus martis aperitivus (*aperiens*), *Ferri peroxidum hydratum*, Br.; *Ferrum oxydatum fuscum*, P. G.—*Oxide of iron*, E.; *Oxyde de fer hydraté*, *Sous-carbonate de fer*, Fr.; *Eisenoxyd Hydrat*, G.

Preparation.—Take of Sulphate of Iron eight troyounces; Carbonate of Sodium nine troyounces; Water eight pints. Dissolve the salts separately, each in four pints of the water: mix the solutions thoroughly, and set aside the mixture, until the precipitate has subsided; then pour off the supernatant liquid, wash the precipitate with water until the washings pass nearly tasteless, and dry it on bibulous paper without heat. *U. S.*

On mixing a solution of sodium carbonate with a solution of pure ferrous sulphate in boiled water, a white precipitate of ferrous carbonate is obtained, which in contact with the air rapidly darkens, changing in color through various shades of green, blue, and olive into brown, carbonic acid being at the same time given off. This change of color is accompanied with its conversion into ferric hydrate, with the exception of small and variable proportions of ferrous carbonate, which escape oxidation. This preparation must, therefore, be regarded as identical, or nearly so, with the ferric hydrates of the Pharmacopœias mentioned above.

Properties.—It is an amorphous reddish-brown powder, inodorous and almost tasteless, and closely resembling ferric hydrate. Dilute muriatic acid dissolves it with slight effervescence, the yellow liquid yielding blue precipitates with ferridcyanide (difference from pure ferric hydrate) and ferrocyanide of potassium, but not with barium chloride (absence of sulphates). If it has been dried at an elevated temperature, it is of a brighter red color, does not readily dissolve in warm dilute muriatic acid, and consists mainly of the oxyhydrate $Fe_2O_3.H_2O$. Dried at ordinary temperature it consists chiefly of the oxyhydrate $Fe_2O_3.Fe_2 6HO$. (See Ferri oxidum hydratum and Ferri peroxidum hydratum.)

Pharmaceutical Uses.—Subcarbonate of iron is used for preparing ferrum redactum, and forms a constituent of Emplastrum ferri and Trochisci ferri subcarbonatis, *U. S.*

Medical Action and Uses.—This is one of the oldest pharmaceutical preparations of iron, and was intended to imitate and take the place of rust of iron, which from time immemorial had been used in medicine. It continues to be one of the most employed members of its class, but is ineligible whenever it is desired to introduce a large amount of iron into the blood; it has been recommended in all forms of *anæmia* and *anæmic chlorosis*, and in *neuralgia*, *chorea*, and other nervous affections depending upon a deficiency of red corpuscles in the blood. In a disease of a different order, *tetanus*, a number of cures have been attributed to this medicine, but of late years it has been entirely supplanted by other means, and the question of its utility is unsettled. Subcarbonate of iron in large doses, mixed with water, may be resorted to when the hydrated peroxide cannot be procured, in cases of poisoning by *arsenious acid.* The *dose* of subcarbonate of iron is from five grains upwards. In some cases of neuralgia it has been taken by the teaspoonful. Caution should be exercised, lest it accumulate in the bowels and obstruct them.

FERRI SULPHAS, *U. S.*, *Br.*—SULPHATE OF IRON.

Ferrum sulfuricum purum, P. G.; *Sulfas ferrosus*, *Ferrum vitriolatum purum*, *Vitriolum martis purum.*—*Ferrous sulphate*, E.; *Sulfate* (*Protosulfate*) *de fer*, *Sulfate ferreux*, Fr.; *Schwefelsaures Eisenoxydul*, G.

Formula $FeSO_4.7H_2O$. Molecular weight 278.

Preparation.—Take of Iron in the form of wire and cut in pieces twelve troyounces; Sulphuric Acid eighteen troyounces; Water eight pints. Mix the sulphuric acid and water, and add the iron; then heat the mixture until effervescence ceases. Pour off the solution, and, having added thirty grains of sulphuric acid, filter through paper, allowing the lower end of the funnel to touch the bottom of the receiving vessel. Place the filtered liquid in a matrass and evaporate until sufficiently concentrated; then set it aside in a covered vessel to crystallize. Drain the crystals in a funnel, dry them on bibulous paper, and keep them in a well-stopped bottle. *U. S.*

Take of Iron Wire four ounces; Sulphuric Acid four fluidounces; Distilled Water one and a half pint. Pour the water on the iron placed in a porcelain dish, add the sulphuric acid, and when the disengagement of gas has nearly ceased, boil for ten minutes. Filter now through paper, and, after the lapse of twenty-four hours, separate the crystals which have been deposited from the solution. Let these be dried on filtering paper placed on porous bricks, and preserved in a stoppered bottle. *Br.*

The British Pharmacopœia recognizes also *Ferri sulphas granulata*, which is prepared by precisely the same process, except that on filtering the solution is collected in a jar containing eight fluidounces of rectified spirit and that the mixture is stirred so that the salt shall separate in granular crystals. These are deprived by decantation of adhering liquid, transferred on filtering paper to porous tiles, and dried by exposure to the atmosphere.

Ferrous sulphate is obtained on a large scale from alum shale and by roasting iron pyrites, exposing it to the air and exhausting the mass with water; also by passing solutions of copper sulphate over scraps of iron, whereby copper is precipitated, the iron entering into solution. It is also obtained as a by-product in various manufactures where sulphuric acid is used for the purpose of purifying certain products. The article thus obtained is usually impure, and not fit for medicinal purposes, except for disinfecting and in this impure state is known in commerce as *copperas*, or *green vitriol* (Couperose verte, Vitriol vert, *Fr.*, Kupferwasser, Grüner Vitriol, *G.*). For medicinal use it should be prepared directly from sulphuric acid acting upon iron wire or clean iron filings in the presence of water, when hydrogen is evolved, ferrous sulphate remaining in solution. $Fe_2 + 2H_2SO_4$ yields $2H_2 + 2FeSO_4$. The salt is prone to oxidation if its chemically neutral solution is evaporated to crystallization; but in the presence of some free sulphuric acid yields crystals which are far more permanent. This explains the necessity of having some free sulphuric acid in the liquid from which ferrous sulphate is crystallized. The crystals are collected upon a diaphragm, washed rapidly with a little water to remove the mother-liquor, and then dried.

Properties.—Ferrous sulphate is in transparent bluish-green monoclinic and rhombic crystals. When the concentrated solution on filtering is allowed to drop into an equal bulk of alcohol, or as directed by the British Pharmacopœia, well agitated with a smaller quantity of alcohol, and the precipitate rinsed with some diluted alcohol, it forms a pale-green crystalline powder, which is more permanent in the air than the large crystals. It has a specific gravity of 1.9, a styptic taste, a slight acid reaction, and when exposed to the air effloresces and is gradually oxidized. It dissolves at 10° C. (50° F.) in 1.64, at

30° C. (86° F.) in 0.7, and at 100° C. (212° F.) in 0.3 parts of water. It is insoluble in alcohol and ether. The aqueous solution yields a white precipitate with barium chloride, a dark-blue one with potassium ferridcyanide, and a bluish-white one with potassium ferrocyanide.

Tests.—Impurities are rarely present if the salt has been prepared from iron and sulphuric acid. The aqueous solution treated with hydrosulphuric acid should not give a blackish precipitate (copper, etc.), and when completely precipitated by sulphydrate of ammonium, the filtrate on evaporation and ignition should leave no residue (magnesium, alkalies). The aqueous solution, after being oxidized with nitric acid and supersaturated with ammonia, should yield a filtrate, which is not affected by sulphuretted hydrogen (zinc, manganese); and if the oxidized liquid is supersaturated with warm potassa solution, the filtrate neutralized with muriatic acid and again supersaturated with ammonia, no precipitate (alumina) should occur.

Pharmaceutical Uses.—Nearly all the officinal compounds of iron, with the exception of the chloride, iodide, sulphide, and nitrate, are prepared from the sulphate, either directly or indirectly. Ferrous sulphate is used in preparing Mistura ferri comp., *U. S.*, *Br.;* Pil. aloes et ferri, *Br.;* Pil. ferri carbonatis, Pil. ferri comp., *U. S.*

FERRI SULPHAS EXSICCATA, *U. S.*, *Br.*—DRIED SULPHATE OF IRON.

Ferrum sulfuricum siccum, P. G.—*Sulfate de fer desséché*, Fr.; *Entwässertes schwefelsaures Eisenoxydul*, G.

Formula $FeSO_4.H_2O$. Molecular weight 170.

Preparation.—Take of Sulphate of Iron in coarse powder twelve troy-ounces. Expose it, in an unglazed earthen vessel, to a moderate heat, with occasional stirring, until it has effloresced; then increase the heat to 300° F., and maintain it at about that temperature until the salt ceases to lose weight. Lastly, reduce the residue to fine powder, and keep it in a well-stopped bottle. *U. S.*

The process of the British Pharmacopœia is the same, except that a porcelain or iron dish is used, and the heat permitted to be raised to about 165° C. (400° F.). Crystallized ferrous sulphate contains 45.3 per cent. of water of crystallization, a portion of which is lost in a dry atmosphere at the ordinary temperature, the remainder except one molecule at 115° C. (239° F.). The last molecule of water is expelled only at about 280° C. (536° F.), and if proper care be taken, without the loss of sulphuric acid.

Properties.—Exsiccated ferrous sulphate forms a grayish-white powder, which dissolves slowly in cold, more rapidly in hot water, leaving only a small quantity of ferric oxysulphate. Otherwise the behavior and tests of purity are the same as for the crystalline salt, nearly 10 parts of which are represented by 6 parts of the exsiccated salt.

Medical Action and Uses.—The intense astringency of the sulphates of iron renders them, as a rule, ineligible for internal administration except when it is intended to exert a directly constringing action upon the capillaries. If the dose much exceed one or two grains, it is apt to occasion gastric pain and vomiting, and the prolonged use of even smaller doses is not without the risk of impairing the digestive function. Besides passive *hemorrhages*, it is well adapted to control excessive secretions produced by debility, as *sweating*, *chronic diarrhœa*, *leucorrhœa*, *gleet*, and *hydruria*. Externally it has been used as an application to the skin in superficial traumatic *erysipelas;* but it is quite useless in the idiopathic form of the disease. A solution of half an ounce of the salt in a pint of water, or an ointment containing two drachms to the ounce of lard, may be employed in the former affection. An ointment made with one or two parts of the dried sulphate to thirty of lard is a useful application in cases of obstinate local *diseases of the skin*, as eczema, intertrigo, and impetigo. It may also aid in healing the sores occasioned by *rupia*, *ecthyma*, *syphilis*, and *scrofula*, but has no advantage over zinc ointment for this purpose.

FERRI SULPHURETUM, *U. S.*—SULPHURET OF IRON.

Sulphuretum ferrosum.—*Sulphide of iron*, E.; *Sulfure de fer*, Fr.; *Schwefeleisen*, G.

Formula FeS. Molecular weight 88.

Preparation.—Iron unites with sulphur in various proportions, some of the compounds, like iron pyrites, FeS_2, being found in nature. The officinal compound is the monosulphide which is solely employed for generating sulphuretted hydrogen. It is made by mixing 3 parts of iron filings with 2 parts of sublimed sulphur, introducing the mixture in *small* portions into a crucible, heated to bright redness, and kept covered after each addition. Or a rod of iron is raised nearly to a white heat and then brought into contact with sulphur; ferrous sulphuret will at once form and melt, and should be permitted to drop into cold water to solidify.

Properties.—It is in yellowish or blackish masses or irregular pieces, which have a metallic lustre, and are permanent in dry air, but are oxidized when kept in a damp atmosphere. It dissolves readily in dilute sulphuric or muriatic acid with the evolution of sulphuretted hydrogen, and without leaving any residue when the sulphuret is pure. As met with it sometimes contains an excess of sulphur, but usually has an excess of iron, and the sulphuretted hydrogen evolved is mixed with hydrogen.

Sulphuretted hydrogen, *hydrogen sulphide*, or *hydrosulphuric acid* is a colorless gas having a disgusting odor suggesting that of rotten eggs. Its specific gravity is 1.19; water dissolves three times its volume of the gas; the solution is not permanent in the air, but is oxidized, water being formed and white sulphur deposited. The formula of sulphuretted hydrogen is H_2S, its molecular weight 34.

Medical Uses.—This compound has no direct medicinal value. It is only used for the production of hydrosulphuric acid.

FERRI VALERIANAS.—VALERIANTE OF IRON.

Ferrum valerianicum.—*Valérianate de fer*, Fr.; *Baldriansaures Eisenoxyd*, G.

Preparation.—This salt is best obtained by adding to a solution of ferric sulphate or ferric chloride a solution of sodium valerianate as long as a precipitate is produced, collecting this upon a filter, washing it with water and drying it at the ordinary temperature.

Properties.—Ferric valerianate is a dark brown-red amorphous powder, having a faint odor and taste of valerian. When slowly heated it parts with its acid without fusing; but when rapidly heated it fuses and gives off inflammable vapors having the odor of butyric acid. It is decomposed by boiling water, ferric hydrate remaining undissolved. It is completely soluble in dilute hydrochloric acid. It contains between 28 and 51 per cent. of ferric oxide, the composition varying with the degree of exposure to heat and probably with the care with which it has been washed.

Medical Action and Uses.—It was expressly stated, when this preparation was first introduced into medicine, that it would be an error to regard it as a true antispasmodic because it contained valerianic acid, and that its value depended mainly upon the iron it contained, the valerianic acid being only an adjuvant. It should have been added that the iron might be introduced into the system under many more eligible forms, and in more suitable doses than were recommended for this salt. It is probably but little used, even for the affections for which it was originally recommended and which were described as "chlorosis with hysterical or epileptiform attacks." It was prescribed in pills in the *dose* of from one to three grains several times a day.

FERRUM, *U. S.*, *Br.*—IRON.

Mars.—*Fer*, Fr.; *Eisen*, G.

Symbol Fe. Atomicity bivalent and sexivalent (Fe_2). Atomic weight 56.

Origin.—Iron is the most useful and one of the most widely diffused metals in nature, being present in most rocks and soils, and generally forming one of the constituents of the ashes of plants and animals. It is rarely found in the metallic state. It is often combined with sulphur as *iron pyrites*, more frequently oxidized as *magnetic iron*, *spathic iron*, *hæmatite*, and other ores, and likewise in combination with mineral acids. It is found in large quantities in several States of North America, and in Great Britain, Sweden, Germany, France, and other European countries.

The manufacture of metallic iron must of necessity vary with the nature of the ore; but the principle is in all cases the same. The ore frequently requires roasting or calcination, mainly for the purpose of rendering it more porous and better adapted for the smelting process; this process is conducted in blast-furnaces, the ore being mixed with carbonaceous matter, coke and the like, some flux, either lime or clay, being added at the same time, whereby a more readily fusible silicate of aluminum and calcium is formed, which, on cooling, forms the glass-like slag. The crude iron obtained from the blast-furnace is called *pig* or *cast iron*, and contains various proportions of carbon, silicon, sulphur, phosphorus, and other impurities, from which it must be purified to adapt it for various uses in the arts. In the *refining* or *puddling* process it is fused, and by stirring brought into contact with a blast of air, by which the impurities are oxidized, or the oxidation is effected with the aid of an impure oxide of iron (iron scales). The slag still remaining in the iron is then, at a white heat, pressed out under a steam hammer, and the iron thus purified rolled out into bars. For many purposes a further purification is requisite.

Properties.—Iron is a grayish metal, of the spec. grav. 7.7 to 7.9. Its tenacity or strength is nearly twice as great as that of any other metal commonly used; and when heated it possesses a ductility admitting of its being drawn into the thinnest wire. It remains unchanged in dry air, but in the presence of moisture its surface becomes covered with brown-red oxide (*rust*). It enters into combination with nearly all the elements, and forms the base of two important series of salts, the *ferrous* and *ferric*, in the former of which it is a dyad, Fe'', in the latter a hexad, Fe_2''' or $(Fe_2)^{vi}$.

Ferrous salts, when anhydrous, are mostly white, and bluish-green in the hydrated state; the oxalate is yellow. When moist or in solution they are easily oxidized on exposure to the air or under the influence of oxidizing agents. Their aqueous solutions are colored brownish-black by nitric oxide, and yield black precipitates with sulphydrate of ammonium, and white ones, changing to green, black, and brown, with alkalies and their carbonates; the precipitation, particularly with ammonia, is incomplete. Soluble phosphates precipitate white ferrous phosphate, changing to greenish-blue; potassium ferrocyanide produces a bluish-white precipitate changing to dark-blue, and potassium ferridcyanide a dark-blue one. Ferrous solutions free from ferric salt are not affected by potassium sulphocyanide or tannin. The soluble chemically neutral ferrous salts have an acid reaction to test-paper; those insoluble in water dissolve in hydrochloric acid.

Ferric salts are either neutral or basic; the neutral salts, when soluble, have an acid reaction, are mostly white when anhydrous, and brown or brown-yellow when hydrated: the basic salts are of a darker brown or reddish-brown color. Those insoluble in water dissolve in muriatic acid. Sulphuretted hydrogen reduces ferric to ferrous salts, sulphur being separated; ammonium sulphydrate produces the same reduction, and afterwards a black precipitate. Alkalies and alkaline carbonates added in excess separate brown ferric hydrate, in the latter case with the evolution of carbonic acid; the precipitation is prevented by the presence of tartaric acid and some other organic compounds. Sodium acetate added in the cold colors the solutions deep brown-red, the color disappearing on the addition of muriatic acid; on boiling, a brown precipitate of basic ferric acetate or ferric hydrate is deposited. Solutions of ferric salts, treated with metallic iron, sulphurous acid, or other deoxidizing agents, are reduced to ferrous salts. Sodium phosphate precipitates white ferric phosphate, which is insoluble in acetic acid, becomes brown by ammonia, and if excess of sodium phosphate be present, dissolves in ammonia with a red-brown color. Arseniate of sodium has a behavior similar to that of the phosphate. Gallo-tannic acid causes a blue-black color and precipitate (writing ink). Meconic acid and sulphocyanides color the solutions blood-red, the color produced by the latter reagent being destroyed by corrosive sublimate and by strong mineral acids. Potassium ferridcyanide darkens somewhat the solutions of ferric salts; potassium ferrocyanide precipitates Prussian blue.

Off. Prep.—Besides ferrum redactum the following *chemical* compounds are officinal: Ferri arsenias, *Br.;* Ferri chloridum, Ferri citras, *U. S.;* Ferri et ammon. citras, *U. S.*, *Br.;* Ferri et ammon. sulphas, Ferri et ammon. tartras, *U. S.;* Ferri et potass. tartras (Ferrum tartaratum), Ferri et quiniæ citras, *U. S.*, *Br.;* Ferri et strychniæ citras, Ferri ferrocyanidum, Ferri hypophosphis, *U. S.;* Ferri iodidum, *Br.;* Ferri lactas, Ferri oxalas, *U. S.;* Ferri oxidum humidum (hydratum), *U. S.*, *Br.;* Ferri oxidum magneticum, Ferri peroxidum hydratum, *Br.;* Ferri phosphas, *U. S.*, *Br.;* Ferri pyrophosphas, Ferri subcarbonas, *U. S.;* Ferri sulphas, Ferri sulphas exsiccata, *U. S.*, *Br.*; Ferri sulphas granulata, *Br.*; Ferri sulphuretum, *U. S.*

The following are solutions of iron salts in water, syrup, or alcohol: Liquor ferri chloridi, Liq. ferri citratis, *U. S.;* Liq. ferri nitratis (pernitratis), *U. S.*, *Br.;* Liq. ferri perchloridi, Liq. ferri perchlor. fortior, *Br.;* Liq. ferri subsulphatis, *U. S.;* Liq. ferri tersulphatis (persulphatis), Syrupus ferri iodidi, *U. S.*, *Br.;* Syrupus ferri phosphatis, Tinctura ferri acetatis, *Br.;* Tinct. ferri chloridi (perchloridi), *U. S.*, *Br.*

The following pharmaceutical preparations contain iron in various forms: Emplastr. ferri, *U. S.*, *Br.;* Ferri carbonas saccharata, Mistura ferri aromatica, *Br.;* Mistura ferri comp., Pil. ferri carbonatis, Pil. ferri iodidi, *U. S.*, *Br.;* Pil. aloes et ferri, *Br.;* Pil. ferri comp., *U. S.*; Trochisci ferri redacti, *Br.;* Troch. ferri subcarbonatis, *U. S.;* Vinum ferri, Vin. ferri citratis, *Br.*

Physiological Action. *On Animals.*—Iron is an essential constituent of the animal economy, and is chiefly found in the red corpuscles of the blood, rendering them fit vehicles for carrying oxygen to every part of the economy. The animals in whose blood the proportion of iron approaches most nearly to that of man, are the ox, the dog, the goose, and the hog. By experiment it has been proved that the quantity of iron in the blood, the bile, and the milk may be increased by administering the metal with the food.

On Man.—In medicinal doses, varying greatly according to the preparation employed, iron does not produce any immediate effects; but, after a variable interval, it gives rise to a condition of plethora with characteristic phenomena. The feces are blackened, either by the formation of salts of iron with the tannic acid of the food, or by the sulphur derived from its decomposition. But preparations which are insoluble in the stomach and the potassio-tartrate have not this effect. A small portion only is excreted with the urine, yet enough in some instances to become a constituent of urinary calculi, and also to provoke a genito-urinary irritation. Doubtless, also, in appropriate morbid conditions, iron may stimulate the sexual functions, as it does all others, by increasing the organic vigor. It augments the excretion of urea, and raises the animal temperature. Some of the preparations are more or less irritant, especially the chlorides, the sulphates, and the iodides, and have occasioned death by their local action on the stomach, an effect due chiefly to the acid associated with the metal. There is little doubt that the whole physiological and therapeutical action of iron depends upon its power of absorbing oxygen from the air in the lungs and carrying it to the various organs and tissues. Its proportion in the blood is, therefore, other things being equal, a measure of the vital activity and energy. It appears that a point of saturation may be reached beyond which the use of iron may, on the one hand, produce plethora, or, on the other, be eliminated from the economy as superfluous. But plethora, it must be remembered, is an exaggerated degree of a normal state.

Medical Uses.—Naturally, iron is chiefly indicated when the proportion of red corpuscles in the blood is permanently diminished. Their transient loss by hemorrhage is better repaired by food, out of which the constituents of the blood are normally elaborated, supposing that the assimilative functions remain unimpaired. But when such impairment exists, the speediest and the surest cure is brought about by the direct introduction of iron into the economy. By its means the proportion of red corpuscles in the blood is directly increased, and their condition, as seen under the microscope, changed from pale and shrivelled to red and full; through them more oxygen is introduced into the system, and a more active assimilation of nutriment, as well as a more perfect renewal of tissue, is secured. The cases in which *anæmia* may be thus remedied comprise idiopathic anæmia, associated or not with chlorosis, hypochondria, convalescence from prolonged and exhausting diseases, malarial and saturnine, and some other cachexiæ attended with imperfect elaboration of the blood or its habitual waste, certain varieties of dyspepsia, some forms of albuminuria, etc. Although in the greater number of *chronic nervous diseases* distinguished by morbid susceptibility the condition of the blood is impaired, and the restoration of this fluid to its normal state is an essential element of the cure, yet it often happens that the disorder is apparently limited to the nervous system, especially when the latter has been directly affected by the morbid cause. In such cases the use of iron is more prejudicial than profitable; it oppresses and does not invigorate, it impairs the appetite, constipates the bowels, and induces a dangerous plethora. When anæmia constitutes only one out of many symptoms of a disease, the use of iron will be more or less efficient according to whether the anæmia depends or not upon removable causes. The anæmia of tuberculosis, of cancer, of certain forms of Bright's disease, and some other affections, is subordinate to an incurable lesion, and iron can, therefore, act only as a palliative. In the case of tubercular phthisis the danger of its causing hæmoptysis must not be overlooked. In these, and, indeed, in nearly all forms of anæmia, iron is food, and, like other food, must be productive of good or evil according to the patient's need of it and his power of assimilating it.

Scanty, as well as excessive, *menstruation* may both be appropriately treated by iron, for either may be due to a deficiency of normal blood. When the catamenia are profuse but watery, they are diminished by iron, and the proportion of solids in the discharge is increased; on the other hand, when they are both scanty and pale, iron is the best agent for increasing them. The former case is the more hopeful one, because it shows a certain energy, with a supply of material; the latter, in its chronic type, is usually a sign of progressive and incurable exhaustion, but sometimes, also, it results from uterine congestion, which must first be treated before iron can be of much avail. This object is usually sought through the use of aloetic purges, and other stimulant and derivative agencies. In all cases of active *uterine hemorrhage*, if there be any such independently of disease of the womb, iron should not be given internally; but, when the flow is passive, the case enters the category of passive hemorrhages generally; and for these, whether they take place from the organ named, from the rectum, bladder, kidneys, or other part, iron becomes one of the best remedies; not, however, as iron, but in combination with a mineral acid, in which compound the astringency is derived from the acid rather than from the ferruginous base. The combinations of hydrochloric and of sulphuric acids with iron are in this respect the most efficient. The stimulant action of iron salts renders them less appropriate for *pulmonary* than for other internal hemorrhages, except in the form of atomized solutions. Iron is useful in regulating the *heart* when it becomes irregular through weakness, whether or not the condition be aggravated by valvular obstruction. By giving tone to this, as well as to other organs, it sometimes permits the removal of dropsies dependent upon cardiac obstruction.

Various *nervous disorders*, more or less dependent upon impoverishment of the blood, may be cured by iron. Of these, the most directly amenable to its operation are *neuralgia*, especially of the fifth pair, and next to this of the gastric nerves; and *chorea*, which, very often, like neuralgia, is the result of debility, and, remotely, of impoverishment of the blood. Of other nervous affections for which iron is appropriate, are various irritations of the bladder and urethra tending to occasion *retention* or *incontinence of urine*, in which the tincture of the chloride, or the solution of the iodide, of iron may be used with much confidence in their virtues. *Seminal emissions* in weak, nervous, and excitable persons may sometimes be prevented by the same agent, especially if associated with belladonna or ergot, which, indeed, render the cure more prompt and certain. The same is true of the use of iron in certain cases of incontinence of urine.

The cure of *insanity* and of *whooping-cough* may be accomplished through iron, like neuralgia and chorea, when they depend upon exhaustion of the nervous system. One of the most valuable results of recent experience in regard to insanity consists in the proof that good food and other hygienic means are essential elements in its proper treatment. In like manner, iron is not a specific for whooping-cough, it only destroys the soil in which that disease tends to gain strength. Iron is contraindicated in *epilepsy*.

Intermittent fever is cured by iron only when the disease is prolonged by exhaustion of the system and impoverishment of the blood, and this occurs especially when the sick remain in malarial localities, and when an appropriate anti-periodic treatment has not been employed. Hence the use of quinia after a course of iron is found to be more efficient than before, in the cases alluded to. Enlargement of the *spleen* may be rapidly lessened by iron, if the affection be not inveterate. In a word, the efficacy of iron in malarial affections is wholly subordinate to its renovating action upon the blood.

The same statement is, in the main, true respecting the use of iron in *dyspepsia*. The medicine acts chiefly by improving the blood, and thereby increasing the secretion of gastric juice and the muscular power of the stomach. But, if acid preparations are used, they also act as local stimulants. Hence the latter should be given immediately before meals, but other martial preparations either along with the food or directly after meals. In either case cinchona and its derivatives are important adjuvants.

The action of iron in *albuminuria* probably consists mainly in its lessening the destruction of the red blood disks, and in a subordinate degree in its local action upon the kidneys. The latter is, however, less probable than the former, since it is alleged that the iron cannot be detected in the urine. It, nevertheless, lessens the proportion of albumen discharged, and in the desquamative forms of Bright's disease often effects a stable cure. This is particularly evident in albuminuria and dropsy occurring after scarlatina, or from the action of cold and dampness upon the skin. But the medicine is still the best, even in granular and in amyloid degeneration of the kidney. The form in which iron is administered is of secondary importance, but probably the best is a solution of muriated tincture of iron in acetate of ammonia, with an excess of acetic acid.

Iron is one of the most important aids to a proper diet in the treatment of *diabetes;* it tends to sustain the general health even when it does not directly cause a diminution in the proportion of sugar excreted. Basham's mixture (which represents the solution mentioned in the last paragraph) appears to be the best form for its administration. In chronic *mucous fluxes* of every description iron is invaluable; in those of the bowels, by its direct application, partly; and in the rest, by its influence upon the blood, and perhaps, also, by constringing the capillary vessels. It is of great value in the treatment of intestinal *worms;* not so much, probably, by directly destroying them as by rendering the intestinal secretions more healthy, and thereby depriving the parasites of their nidus. Among mucous profluvia, *chronic bronchitis* is often cured by iron, especially when the sputa are muco-purulent. Hence the reputation of the compound iron mixture as an anti-hectic medicine; and hence also the error of applying the same treatment to consumption of the lungs. True pulmonary *phthisis*, with tissue degeneration, is benefited by iron only in so far as its use is proportioned to the diminished blood formation belonging to that affection. It may be not only tolerated, but useful while active exercise can be taken; but unless great care is exercised, it increases the tendency to hæmoptysis, and hastens the progress of the disease. It is most readily tolerated by the dull and lymphatic, when there is but little tendency to febrile irritation, and when the disorder is essentially chronic. Iron is more appropriate in the histologically allied, but clinically quite different, disease, *scrofula;* but even in this affection, its value, except to meet incidental conditions, such as anæmia and dyspepsia, is not great. The iodide of iron is probably useful in glandular scrofula in virtue of the iodine it contains. In *syphilis* and *cancer*, for which iron has been recommended, it has no other virtues than arise from its power of sustaining the general health, or, in the case of the former disease, of mitigating the mischiefs of an excessive use of mercury.

The most efficient remedy in idiopathic *erysipelas* is the tincture of the chloride of iron given in full and repeated doses, such as from twenty to forty drops every two or three hours, properly diluted. Smaller doses are quite useless. Its action is probably to constringe the capillary bloodvessels, although its acid element may directly tend to antagonize the febrile poison.

The same preparation has been reported to act very favorably in low forms of *scarlatina*, *measles*, and *puerperal fever;* but although there is no reason to reject its use, there is not enough to recommend it. The sulphuret of iron has been proposed as an antidote to constitutional *poisoning by lead*, and as a means of neutralizing the salts of *mercury*, *lead*, *antimony*, *copper*, and especially *arsenic* in the stomach. For the last-named the hydrated oxide is generally employed, but it probably acts by mechanically enveloping the particles of arsenic rather than as a chemical antidote. The same remark applies to the insoluble saccharated oxide of iron.

The *contraindications* for the use of iron it is essential to keep in mind. The one which surpasses all others in importance is feverishness. Almost the only exception to this statement is that tincture of chloride of iron cures erysipelas;

but it doubtless acts, not as iron, but as a powerful astringent. In nearly all other cases fever, or even feverishness, should exclude iron, whether it be produced by chronic disease, as phthisis, or by local irritations, such as dyspepsia with constipation. In this affection the tongue is apt to be coated, not by continuous or any other "sympathy" with the gastro-intestinal disorder, but because the local disorder produces general feverishness. Under such circumstances purgation is an esential preliminary to the favorable action of iron; and hence the saline chalybeate mineral waters are very efficient in such cases.

The local therapeutical uses of iron are numerous, but they owe their value to the astringency of the acid compounds of the metal rather than to the metal itself. Solutions and ointments of the sulphate have been applied with apparent advantage in traumatic *erysipelas*, in *phlegmasia alba*, and in various chronic eruptions of the *skin* occurring in persons in whom these affections tend to ulcerate or to persist unchanged. The subsulphate, in strong solution, has been applied to the cure of nasal, aural, and other *polypi;* and in weak solution to arrest chronic *mucous discharges* from the urethra, vagina, etc. Solution of chloride of iron represses *fungous granulations* in cases of ingrown toe-nail, ulcerated gums, etc.

Like other astringents, salts of iron may be used in the treatment of varicose or simply dilated bloodvessels of the *conjunctiva*, and in relaxed conditions of the *fauces*. The solution of chloride of iron is said to be useful as a local application in *diphtheria*, and it probably is so when the exudation is in its forming stage and of limited extent. It is worse than useless when the false membrane is extensive and thick. In the decline of the disease, gargles containing a small proportion of the solution tend to constringe the part, and renew its healthy action. It and the sulphate of iron are hæmostatics, and have often arrested threatening *hemorrhage* in epistaxis, gastric hemorrhage, that from the extraction of teeth, leech-bites, the excision of tonsils, cancerous ulceration, and hemorrhage after delivery. In the last case it must be sufficiently diluted with water, and carefully pumped into the uterine cavity. In pulmonary hemorrhage an atomized weak solution (one part of the tincture to ten parts of water) has been inhaled with prompt effect. The injection of solutions of the lactate, the perchloride, and other salts of iron into varicose and other *aneurisms*, would form an eligible method of treatment if it were not extremely dangerous. In a number of instances the operation has been speedily followed by the patient's death, either suddenly by embolism, or later by ulceration.

FERRUM DIALYSATUM.—DIALYZED IRON.

Liquor ferri dialysati.—Fer dialysé, Fr.; *Dialysirtes Eisen*, G.

Preparation.—Dialyzed iron is made by saturating an aqueous solution of ferric chloride with ferric hydrate, putting the liquid into a dialysator, and suspending this in water, which is often renewed, as long, indeed, as it acquires an acid reaction. Very little iron will pass through the parchment septum; when dialysis is completed, the ferric solution is diluted so that 100 grains of it, when evaporated and dried at a temperature not exceeding 100° C. (212° F.), will leave a solid residue weighing 5 grains. In France the following process has been adopted: 100 grams of solution of ferric chloride of 30° B., are mixed in small quantities with 35 grams ammonia water of 22° B. The precipitate dissolves at first rapidly, afterwards very slowly. When the liquid has become transparent it is introduced into a dialysator, and treated as stated before; eight to ten days are required in the preparation.

Properties and Tests.—Similar solutions were obtained by Ordway (1858) and Béchamp (1859) by leaving pure ferric hydrate in contact with ferric chloride for a prolonged time. Th. Graham (1861) subjected this to dialysis, and succeeded in removing the acid until chlorine corresponding to 1.5 per cent. of HCl was left. Such a solution, however, which would correspond to $Fe_2Cl_6.95Fe_2O_3$, gelatinized ultimately. Hager (1868) found dialyzed iron to have the composition $Fe_2Cl_6.12Fe_2O_3$; Ordway's oxychloride was $Fe_2Cl_6.23Fe_2O_3$. It is evident, therefore, that dialyzed iron may have a somewhat varying composition. Some solutions may be boiled without being precipitated, but they cannot be evaporated by heat to dryness without losing their solubility. The solution has a deep brown-red color, and is almost destitute of styptic taste. It is miscible with alcohol, glycerin, syrup, and distilled water, but not with spring water, or other even dilute saline solutions. A small quantity of tannin merely darkens the liquid, a larger quantity causes a deep brown gelatinous precipitate. A minute quantity of nitrate of silver will not disturb the liquid; a larger quantity will cause a gelatinous brown precipitate, which is again soluble in distilled water; but on adding first a slight excess of ammonia, filtering from the ferric hydrate, acidulating with nitric acid, and then testing with nitrate of silver, a white precipitate of chloride of silver is formed.

It is a dark reddish-brown liquid, perfectly transparent in thin layers, and nearly free from ferruginous taste. It is best given alone, or diluted with a simple solvent.

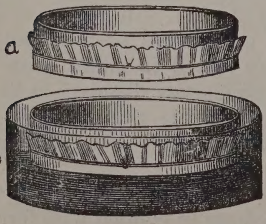
H. Trimble (1878) has analyzed six samples met with in commerce, and found the saline portion to vary in amount between 2.51 and 4.83 per cent., and in composition between $Fe_2Cl_6.11Fe_2O_3$ and $Fe_2Cl_6.31Fe_2O_3$. A solution which, when evaporated on a water-bath until the residue is pulverulent and weighs 5 per cent., has, according to E. B. Shuttleworth (1877), the spec. grav. 1.034. If 5 per cent. of residue is left after completely drying in a water-bath, the spec. grav. is 1.040; and if the same amount of residue is left after ignition, the spec. grav. of the solution is 1.046.

Prof. E. Scheffer (1878) shows that by precipitation with ammonia very basic oxychlorides of iron may be obtained, which, after having been thoroughly washed, will slowly dissolve in distilled water. The limits at which a soluble precipitate is obtained appear to have been reached on mixing 150 volumes of the officinal solution of ferric chloride with 91.5 volumes of ammonia water. The washed precipitate contained 97.83 per cent. Fe_2Cl_6 to 2.17 per cent. Fe_2Cl_6, and required over seven weeks for effecting solution in distilled water. The preparation known in some parts of Europe as *Ferrum catalyticum* is probably made by a similar process.

On precipitating a solution of ferric chloride with an excess of ammonia, the hydrate of iron invariably retains ammonia, and, on being added to ferric chloride, ammonium chloride is produced, which sets a limit to the solution of ferric hydrate; the basicity of such a preparation must necessarily be in an inverse ratio to the quantity of ammonium chloride contained in it, but it may be increased by subjecting it to dialysis.

The process of *dialysis* depends upon the difference in the diffusing power possessed by solid bodies when in solution. Graham (1861) ascertained that the power of diffusing from one liquid into another is greatest in those bodies which are capable of assuming a crystalline form, and that those which are amorphous and capable of forming with water a gelatinous mass, are but very slightly and slowly diffusible. He distinguished the former as *crystalloids*, and the latter as *colloids*. When both are together in aqueous solution, and separated by a septum of animal membrane or parchment paper from water, the crystalloids only will pass through the septum, and may thus be completely separated from the colloids. The dialyser or dialysator is

Fig. 72.



a, Dialyser; *b*, The same in use.

conveniently made from a section of a glass cylinder or a wooden hoop, or from gutta percha, or similar insoluble material. The septum is made to cover one aperture of the short cylinder, and, after having been securely fastened, is permitted to project above. If the dialyser is larger than about 10 or 12 inches in diameter, its sacking in the centre may be prevented by means of a net, stretched over it, or used for supporting it. The liquid should not be more than about one-half inch deep upon the septum, and should never be immersed below the surface of the water in the outer vessel; on the contrary, it is best to keep the surface of the dialyzing liquid higher, so as to prevent it from becoming too dilute by the upward dialysis of water. The water in the receiving vessel should be changed daily, or, if possible, provision should be made for a continuous supply of distilled water, and for the simultaneous removal of the saline solution from the bottom. The extent of surface of the septum, depth of the dialyzing liquid, and the frequency of renewal of the water in the receiver, are the main conditions which influence the success of the process. The dialysis of a solution of oxychloride of iron requires from 1 to 2 weeks, and is known to be finished when the liquid has lost its ferruginous taste, and the dialysate or diffusate in the receiver shows merely traces of chlorides. The residue upon the septum is then assayed by evaporating 100 grains of it, in a water-bath, to complete dryness; from the weight obtained the amount of water which is necessary to bring the whole amount of the liquid to the standard of 5 per cent. is easily determined. If the process has been properly managed, evaporation will not be necessary, and should be avoided, as it interferes with the stability of the preparation.

The best material for the septum is *parchment paper*, which is made by immersing unsized paper for a short time, and at the ordinary temperature, in sulphuric acid, sp. grav. 1.56 to 1.60; the paper is afterwards well washed with water. Bladder may likewise be used, but is less efficient. A bladder may be completely filled with the solution of ferric oxychloride, well tied, and immersed in water; it must be strong enough to sustain a considerable amount of pressure caused by the dialysis of water into the iron solution.

Medical Action and Uses.—The merits of dialyzed iron are claimed to be that it has no styptic taste, mixes well with water in any proportion, and does not stain the teeth or cause constipation. On pharmaceutical grounds "the action of dialyzed iron upon animal products forbids us to suppose *à priori* that it acts like other ferruginous preparations" (Depaire); and a very competent judge (Bouchardat) has declared that, "theoretically, dialyzed iron must be regarded as an inert, or, at best, a very feeble preparation of iron." We have found it utterly to fail in cases for which iron appeared to be the proper remedy, and which other preparations caused to speedily improve. The *dose* is about thirty drops. The following formula has been employed: ℞. Ferri oxid. dialysat., Aquæ cinnamomi, āā f℥j; Glycerin., Alcohol. dil., āā fʒiss.—M. S.—A dessertspoonful three or four times a day. If the views elsewhere expressed of iron as an antidote to arsenic be correct, the proposed use of dialyzed iron for the purpose is unwarranted.

FERRUM REDACTUM, *U. S.*, *Br.*—REDUCED IRON.

Ferrum reductum, P. G.; *Ferrum hydrogenio reductum, Ferrum ope hydrogenii paratum.—Iron reduced by hydrogen, Iron by hydrogen*, E.; *Fer réduit par l'hydrogène*, Fr.; *Reducirtes Eisen*, G.

Preparation.—Take of Subcarbonate of Iron thirty troyounces. Wash the subcarbonate thoroughly with water until no traces of sulphate of sodium are indicated by the appropriate tests, and calcine it in a shallow vessel until free from moisture. Then spread it upon a tray, made by bending an oblong piece of sheet iron in the form of an incomplete cylinder, and introduce this into a wrought-iron reduction-tube, of about four inches in diameter. Place the reduction-tube in a charcoal furnace; and, by means of a self-regulating hydrogen generator, pass through it a stream of hydrogen gas, previously purified by bubbling successively through solution of subacetate of lead diluted with three times its volume of water, and through milk of lime, severally contained in four-pint bottles about one-third filled. Connect with the further extremity of the reduction-tube a lead tube bent so as to dip into water. Make all the junctions air-tight by appropriate lutes; and, when the hydrogen has passed long enough to fill the whole of the apparatus to the exclusion of atmospheric air, light the fire, and bring that part of the reduction-tube occupied by the subcarbonate to a dull-red heat, which must be kept up so long as the bubbles of hydrogen, breaking from the water covering the orifice of the lead tube, are accompanied by visible aqueous vapor. When the reduction is completed, remove the fire, and allow the whole to cool to the ordinary temperature, keeping up, during the refrigeration a moderate current of hydrogen through the apparatus. Withdraw the product from the reduction-tube, and, should any portion of it be black instead of iron-gray, separate such portion for use in a subsequent operation. Lastly, having powdered the reduced iron, keep it in a well-stopped bottle.

When thirty troyounces of subcarbonate of iron are operated on, the process occupies from five to eight hours. *U. S.*

Take of Hydrated Peroxide of Iron one ounce; Zinc, granulated, a sufficiency; Sulphuric Acid a sufficiency; Chloride of Calcium a sufficiency. Introduce the hydrated peroxide of iron into a gun-barrel, confining it to the middle part of the tube by plugs of asbestos. Pass the gun-barrel through a furnace, and when it has been raised to a strong red heat, cause it to be traversed by a stream of hydrogen gas developed by the action on the zinc of some of the sulphuric acid diluted with eight times its volume of water. The gas before entering the gun-barrel must be rendered quite dry by being made to pass first through the remainder of the sulphuric acid, and then through a tube eighteen inches long, packed with small fragments of the chloride of calcium. The further end of the gun-barrel is to be connected by a cork with a bent tube dipping under water, and when the hydrogen is observed to pass through the water at the same rate that it bubbles through the sulphuric acid, the furnace is to be allowed to cool down to the temperature of the atmosphere, the current of hydrogen being still continued. The reduced iron is then to be withdrawn, and inclosed in a dry stoppered bottle. *Br.*

In all essential details the two processes are identical. The drying of the hydrogen is unnecessary, but provision must be made to prevent the acid liquid in which hydrogen is generated from being mechanically carried over; this is effected by passing the gas through an empty vessel before it enters the reduction-tube, or through basic acetate of lead, which will retain also gaseous impurities with which the hydrogen may be contaminated from impurities of the zinc or acid. The reduction-tube, we think, should be filled with hydrogen gas before it is heated to redness. The heat converts the ferric hydrate used into ferric oxide, which is decomposed by the hydrogen with the liberation of iron and the production of water; $Fe_2O_3+3H_2$ yields Fe_2 and $3H_2O$. That the reduction has been completed is ascertained from the absence of aqueous vapor in the bubbles breaking through the water, or from the uniform rapidity with which the bubbles pass both through the water and through the liquid placed between the generator and reduction-tube. After the fire is withdrawn, the reduced iron would burn again to ferric oxide, if it were allowed to come into contact with oxygen while warm; the hydrogen must therefore be continually passed through the reduction-tube until the temperature has been lowered to that of the surrounding atmosphere.

Various other methods have been suggested for obtaining reduced iron, but they do not appear to be used on a large scale. For reduction in a current of hydrogen Peligot (1844) proposed ferrous chloride, and Woehler (1855) ferrous oxalate, or an oxide obtained by strongly heating a mixture of ferrous sulphate and sodium chloride, and washing out the soluble salt. A. Morgan (1854) recommended the calcination of a mixture of ferric oxide, potassium ferrocyanide, and potassium carbonate, each previously deprived of water. Zaengerle (1857) used ferrous oxalate instead of ferric oxide. After cooling, the mass requires to be well washed and dried.

Properties.—Reduced iron is a very fine gray powder, free from metallic lustre, but exhibiting metallic streaks when rubbed with firm pressure in a mortar, and yielding a lustrous scale when struck on an anvil with a hammer. It is wholly dissolved by dilute muriatic or sulphuric acid with the evolution of hydrogen, which is free from noxious odor, and does not impart a black color to filtering paper moistened with solution of lead acetate, and stretched over the orifice of the test-tube; the black color would be due to the presence of sulphur resulting from the sulphate which remains in incompletely washed ferric hydrate. The solution obtained should not assume a red color when tested with sulphocyanide of potassium, proving the absence of ferric or rather magnetic oxide; the presence of magnetic oxide is indicated by the black instead of gray color of the powder. Treated with iodine or bromine, dissolved in solutions of potassium iodide or bromide, the iron will be all dissolved, while the black oxide remains behind; the former is used as a test by the British, the latter by the German Pharmacopœia, both permitting 50 per cent. residue, which should be completely soluble in hydrochloric acid. When reduced iron is touched with a lighted taper, it ignites and burns to brown ferric oxide.

Tests.—The pharmaceutical purity of reduced iron is indicated by the behavior described above; but the exact amount of the most generally present oxide is not easily determined. For an interesting paper on this subject by Mr. Creuse, consult *Proceedings of the Amer. Pharm. Association*, 1874, p. 435. In this paper it is suggested to determine the amount of pure iron from the measure of the hydrogen given off. The presence of oxides, however, appears to interfere with the correctness of the results. Schacht (1877) regards the following as sufficient evidence of purity: It is "a very fine gray powder without gloss; when heated in the air it burns to ferric oxide. It is completely soluble in warm diluted pure muriatic acid, with the evolution of hydrogen, which is indifferent to lead paper. When treated for half an hour, at the ordinary temperature and with occasional agitation, with 25 times its weight of solution of ferric chloride, sp. gr. 1.30, it is completely dissolved."

FERRUM PULVERATUM or *pulverized iron* may be mistaken for reduced iron. It is made in Europe on a large scale from a good quality of cast iron, and therefore contains carbon. It has the general properties of reduced iron, from which it differs in being denser, in being of a distinct metallic lustre, and in not igniting when touched with a lighted taper; the hydrogen evolved by it has a distinct odor, but should contain traces only of sulphuretted hydrogen. The solution of iron in muriatic acid should not yield a dark color or precipitate with sulphuretted hydrogen (absence of lead, copper, etc.), and when oxidized with nitric acid and treated with ammonia in excess, the filtrate should be colorless (copper, etc.), and not be rendered turbid by hydrosulphate of ammonium.

Off. Prep.—Pil. ferri iodidi, *U. S.*

Medical Action and Uses.—This preparation was originally proposed as a substitute for subcarbonate of iron, as being less bulky, and, therefore, more likely to agree with the stomach; but not improbably there happened in this case what has often been observed when the nutritious elements of food were substituted for that form of it which nature provided. In point of fact it is even more likely to derange the stomach than the preparation mentioned, partly on account of the impurities it sometimes contains to the extent of fifty per cent., and partly because it is very apt to cause the formation in the stomach, and the eructation, of sulphuretted hydrogen. Moreover, when given in pills and pastilles, they often escape the solvent power of the digestive juices, and are evacuated in the same form in which they were swallowed. The only way in which it can be administered with an assurance of its solution and absorption is to give it at meal times, or immediately afterwards, in a wafer or suspended in a little water. It may be prescribed in the *dose* of from one to five grains.

FICUS, *U. S.*, *Br.*—FIG.

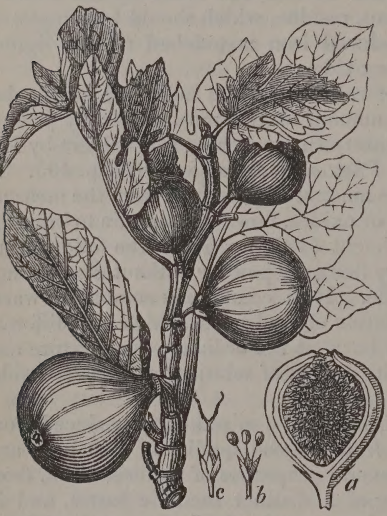
Caricæ, P. G.; *Ficus passa*, *Fici*, *Fructus caricæ.*—*Figue*, Fr.; *Feige*, G.

The fleshy receptacle, bearing fruits upon its inner surface, of Ficus carica, *Lin.* Steph. and Church, Med. Bot. plate 154; Bentley and Trimen, Med. Plants, 228.

Nat. Ord.—Urticaceæ, Artocarpeæ.

Origin.—The fig tree is indigenous to Western Asia, and has been cultivated from a very remote period. At present it is cultivated in most countries of the Old and New World which lie in the warmer temperate regions, in many of which it is also found wild. It attains a height of about 18 feet, is irregularly branched, has rough palmately lobed, irregularly toothed subcordate leaves, in the axils of which appear the fleshy hollow receptacles, upon the inner surface of which the minute flowers are situated, the few staminate flowers being placed near the mouth.

Fig. 73.



Ficus carica, *Lin.*—*a.* Section of fig. *b.* Staminate, *c.* Pistillate flower.

Description.—The receptacle, erroneously called fruit, is pear-shaped, short-stalked, and about 3 inches long; in the green state it contains a milky, acrid juice, which changes to saccharine, the color of the receptacle becoming yellowish and purplish. The orifice is surrounded by several fleshy scales, and the greater portion of the inner surface is covered in the ripe fig by numerous small yellowish akenes, popularly called seeds. Figs have a peculiar fruity odor, and a very sweet, somewhat mucilaginous taste. A warm and dry climate is best adapted for growing figs with the view of preserving them in the dry state.

They are dried either by artificial heat or by exposure to the sun, and packed in this condition (*natural figs*), or they are rendered pliant by kneading and squeezing, and then packed and pressed into boxes (*pulled figs*). In the latter condition they are always of a very irregular shape, yellowish, somewhat translucent, and covered with effloresced sugar. The large pulpy figs are known as *Turkey* or *Smyrna figs*, the small and drier ones as *Greek figs*.

Constituents.—Exclusive of the akenes, which, together with the cellular tissue, Bley (1831) found to constitute about 15 per cent. of the weight of figs, he obtained 16 per cent. of water, 62.5 per cent. of sugar (glucose), the remainder being, gum, fat, and saline constituents.

Off. Prep.—Conf. sennæ, *U. S.*, *Br.*

Medical Uses.—The saccharine and mucilaginous constituents of figs render them nutritive, and in their fresh state laxative. The laxative operation of dried figs is mainly due to the indigestibility of their seeds and tough skins, which also tend to occasion flatulence. They form an agreeable addition to the various ptisans employed in *catarrhal affections* of the air-passages and other mucous canals, and roasted figs have, from time immemorial, formed convenient cataplasms for *gum-boils*, *abscesses* of the *anus*, *vulva*, etc.

FILIX MAS, *U. S.*, *Br.*—MALE FERN.

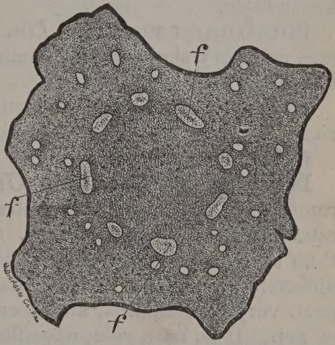
Rhizoma filicis, P. G.; *Radix filicis maris.*—*Male shield fern*, E.; *Rhizome* (*Racine*) *de fougère mâle*, Fr.; *Wurmfarnwurzel*, *Waldfarnwurzel*, *Johanniswurzel*, G.

The rhizome covered with portions of the stipes of Aspidium (Nephrodium, *Brown;* Polypodium, *Lin.*) filix mas, *Swartz.* Woodv., Med. Bot. plate 271.

Nat. Ord.—Filices.

Origin.—Male fern is indigenous to Canada, westward to the Pacific Ocean, thence south along the Rocky Mountains to Mexico and a considerable portion of South America; to some of the Polynesian Islands; to the greater portion of Asia north of the Himalaya Mountains; and to Europe and some parts of Africa. The rhizome is 6 to 12 inches long, has the old portion densely covered with the remnants of the stipes, and produces at the living end from 3 to 6 fronds, which are 1 to 3 feet high, lanceolate in outline, with linear-lanceolate, pinnate, or pinnatifid leaflets, and with oblong obtuse pinnules, which are serrate at and near the apex, and bear the fruit-dots in two rows near the midrib. The rhizome is collected in the autumn.

Fig. 74.



Transverse section of rhizome of Aspidium filix mas, *Sw.*—*f.* Fibro-vascular bundles.

Description.—As found in commerce it is 3 to 6 inches long, and with the closely imbricated remnants of the stipes 2 to 3 inches thick. The latter remain green in their lower portion for several years, and are, like the rhizome itself, densely covered with a brown chaff, consisting of thin transparent scales; between the stipes are the black wiry rootlets. The rhizome itself is fleshy, about 1 inch in diameter, internally of a pale-green color, and shows upon the transverse section near the surface 8 to 12 larger fibro-vascular bundles, arranged in a circle, outside of which are a number of smaller ones. The stipes have about 8 vascular bundles in a loose circle. It has a slight disagreeable odor and a sweetish, afterward somewhat bitter, acrid, and astringent taste. For medicinal purposes, the dead portions of the stipes and rhizome must be removed, and the green part only retained, which should be at once dried, powdered, and exhausted by ether for preparing the oleoresin.

Constituents.—Male fern has been frequently analyzed. Geiger (1826) obtained 6.9 per cent. of green fixed oil, which Luck (1851) found to consist of the glycerides of *filixolic* and *filosmylic acids*, the last of which is volatile. The tannin of older authors was separated by Luck into two acids, *tannaspidic* and *pteritannic acids*, the last only being soluble in ether, both coloring ferric salts green. Malin (1867) found only one tannin, *filitannic acid*, which on being boiled with dilute sulphuric acid is split into sugar and *filixred*, the latter in an impure condition, being Luck's tannaspidic acid. Peschier (1826) obtained from the ethereal extract granular crystals, which Luck named *filicic acid*. Jabowski (1867) gave it the formula $C_{14}H_{18}O_5$, and found it to be decomposed by potassa near the fusing point, into *phloro-glucin* and butyric acid. Pavesi's *aspidin* (1861) is a very impure filicic acid, which is probably the main active ingredient. Starch, gummy matter, sugar, and 2 to 3 per cent. of inorganic salts are the less important constituents.

Allied Drugs.—ASPIDIUM MARGINALE, *Willd.*, differs from male fern mainly in having a thicker almost coriaceous frond with somewhat scythe-shaped nearly entire pinnules, and the fruit dots close to the margin. The rhizome closely resembles the officinal drug, from which it is distinguished by its rather smaller dimensions and smaller vascular bundles, which are about six in number. It appears to be often collected in the United States, where it is indigenous, in place of male fern. J. L. Patterson (1875) obtained from it filicic acid and a tannin similar to if not identical with that of filix mas. C. H. Cressler (1878) found the oleoresin effectual in several cases of tapeworm.

ASPLENIUM FILIX FŒMINA, *Bernh.*, and ASPL. THELYPTEROIDES, *Mich.*, have thin rhizomes which are densely covered with black, thin, two-edged remnants of the stipes; and have numerous black roots, but little scaly chaff.

ASPIDIUM SPINULOSUM, *Swartz*, has a thin rhizome, with about six small fibro-vascular bundles, and with dark-brown nearly cylindrical stipe remnants, between which little or no chaff is found.

OSMUNDA REGALIS, *Lin.* The rhizome is about half an inch thick, densely covered with numerous brown stipe remnants, and of a mucilaginous, slightly bitter taste.

POLYPODIUM VULGARE, *Lin.* The rhizome is thin, flattish, with rather distant and very short stipe remnants on the upper side, and with hair-like roots on the lower side.

Aspid. marginale and Asplen. thelypteroides are indigenous to North America; the other species are found both here and in Europe.

Off. Prep.—Oleoresina filicis (Extr. filicis liquid.), *U. S.*, *Br.*

Medical Action and Uses.—Male fern was anciently known to be a remedy for *tænia* and other intestinal worms, but its reputation was more firmly established in the last century. It is more efficacious in removing the unarmed than the armed tænia, unless the latter be young. The methods employed by different physicians in the treatment of tænia by male fern are, for the most part, very complicated, and seem devised more in a spirit of charlatanism than of art. It is, as a rule, essential that the bowels should contain no accumulation of partially digested food or of feces, and that the vigor of the parasite should be reduced by as low and simple a diet as can well be borne, and chiefly in a liquid form, as milk or broth. Early in the morning, fasting, the patient should take from thirty to ninety grains of powdered male fern, at a single dose, or in divided doses at short intervals. The oleoresin of male fern, in the dose of from ten to twenty drops, may be administered along with the powdered root, or, in feeble persons, by itself. About an hour after the last of these doses an active purge of calomel with jalap or amboge is sometimes administered; but generally an ounce of castor oil will suffice. Some prefer Epsom salts. It is by certain authorities recommended to give a full dose of sulphuric ether shortly after the purgative medicine for the purpose of rendering the detachment of the parasite easier. Since the introduction into practice of the oleoresin of male fern, this preparation should be given, instead of the powder, in the *dose* of from half a fluidrachm to a fluidrachm, at intervals of an hour, for two or three times, and be followed by a purge. The oleoresin is conveniently administered in gelatin capsules. The *dose* of filicic acid is about thirty grains.

FŒNICULUM, *U. S.*—Fennel.

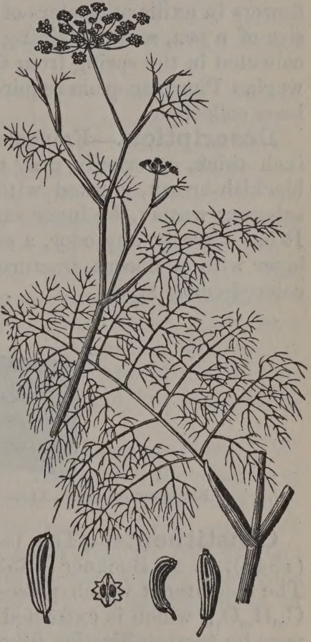
Fœniculi fructus, Br.; *Fructus fœniculi*, P. G.; *Semen fœniculi.*—*Fennel fruit, Fennel seed*, E.; *Fruits* (*Semences*) *de fenouil*, Fr.; *Fenchelsamen*, G.

The fruit of Fœniculum vulgare, *Gaertn.* (s. F. officinale, *All.*, s. Anethum fœniculum, *Lin.*).

Nat. Ord.—Umbelliferæ, Orthospermæ.

Origin.—The fennel is indigenous to Southern Europe, and is frequently found wild in Western and Southeastern Europe and in Western Asia. Commerce is mainly supplied with the fruit from Germany and France. The plant is an herbaceous perennial, varying in cultivation considerably in size and in its fruit. The stem is three to six feet high, somewhat furrowed, green, and glaucous; the leaves are decompound or twice pinnate, with the pinnæ very narrow; the umbels are at the top of the stem, compound, large, and without involucre or involucel. All parts have an agreeable aromatic odor and a sweetish aromatic taste.

Fig. 75.



Fœniculum vulgare.

Description.—The fruit is oblong in shape, nearly cylindrical, and readily splitting at maturity into the two mericarps which often become somewhat curved. The face is broad and flat, the back rounded, and has five prominent obtuse ribs of a light-brown color, the intervening furrows being almost blackish-brown. There are usually six oil tubes, one under each furrow, and two, or in some varieties two pairs, on the face.

The commercial varieties are *Saxon* or *German fennel*, which is about one-quarter of an inch long, and of a brownish tint; and *Roman fennel*, which is nearly twice as large, is of a distinct greenish tint, and has a stronger and more pleasant odor. The latter is often referred to *Fœn. dulce*, D. C., but appears to be merely a variety of F. vulgare produced by cultivation.

Constituents.—Fennel contains about 12.5 per cent. of fixed oil, some sugar, and from 2 to 4 per cent. of volatile oil, to which the sweet taste of the fruit is chiefly due. (See Oleum fœniculi.)

Off. Prep.—Aqua fœniculi, *U. S.*, *Br.*; Tinct. rhei et sennæ, *U. S.*

Medical Action and Uses.—Employed by the ancients as a carminative and digestive stimulant, and to promote the secretions, it continues to be used for like purposes at the present day. It is still alleged to increase the secretion of milk, urine, perspiration, and mucus, and to be an active emmenagogue. It is most commonly used as an ingredient in carminative compounds, or as a simple infusion for the relief of *nausea* and of *colic*. It is very appropriate in hot infusion, as an adjuvant, in the treatment of *amenorrhœa* from uterine congestion, and for re-establishing the *lacteal secretion* when suppressed. An infusion of fennel may be made with sixty grains of the bruised seed in half a pint of boiling water. Of this a teaspoonful may be given at short intervals to an infant, and a wineglassful to an adult.

FRANGULA.—Frangula Bark.

Cortex frangulæ, P. G.—*Alder buckthorn, Black alder*, E.; *Bourdaine, Bourgène*, Fr.; *Faulbaumrinde*, G.

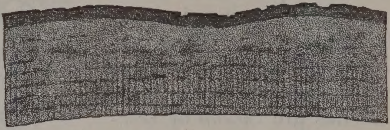
The bark of Rhamnus frangula, *Lin.*, s. Frangula vulgaris, *Reichenb.* Bentley and Trimen, Med. Plants, 65.

Nat. Ord.—Rhamnaceæ.

Origin.—The alder buckthorn is a shrub, about 10 to 15 feet high, which grows in wet places from the northern coast of Africa, throughout Europe, and extending eastward into Siberia. It has alternate elliptic, oval or obovate entire leaves, which are obtuse or slightly pointed at the apex; greenish hermaphrodite flowers in axillary clusters of three or five, and red, finally black berries of the size of a pea, and containing two or three roundish-angular seeds. The bark is collected in the spring from the younger trunks and large branches. The Norwegian Pharmacopœia requires it to be used not sooner than a year after it has been collected.

Description.—Frangula bark is in small quills, about one-twenty-fifth of an inch thick, externally gray or grayish-brown, or from the younger branches blackish-brown, marked with numerous small, whitish, transversely elongated suberous warts; the inner surface is smooth, orange-yellow or brownish-yellow. It has scarcely any odor, a sweet and bitterish taste, and breaks in the inner layer with a fibrous fracture, showing the yellow bast fibres, and a purplish-colored corky layer.

Fig. 76.



Rhamnus frangula, *Lin.*—Transverse section of bark magnified fifteen diameters.

Constituents.—The bark was analyzed by Gerber (1828), Binswanger (1849), L. A. Buchner (1853), Casselmann (1857), Phipson (1859), and others. The constituent which possesses most interest is *frangulin* or *rhamnoxanthin*, $C_{20}H_{20}O_{10}$, which is extracted from the bark by carbon bisulphide, and obtained pure by recrystallization from alcohol and ether. It is a lemon-yellow crystalline mass, of a slight silky lustre, without odor and taste; by sublimation it is obtained in yellow needles. It is insoluble in water, slightly soluble in cold alcohol and ether, and freely soluble in alkalies with a bright-purple color. It dyes silk, wool, and cotton, and is resolved by acids into sugar and frangulic acid, $C_{14}H_{10}O_5$. The bark contains also a yellow resinous principle, tannin, producing brown-green precipitates with iron salts, an amorphous bitter principle which appears to have a purgative action, and various ordinary principles. It yields five or six per cent. of ash. The odor of the fresh bark is due to a volatile principle which has not been isolated. Liebermann and Waldstein (1876) obtained *emodin* from old frangula bark.

Medical Action and Uses.—The fresh bark excites nausea, colic, vomiting, and violent purging, but by drying it loses in some degree its acrid qualities, and is then used in Germany as a domestic purgative. It is stated to be employed as a substitute for rhubarb, but its action is much harsher. A decoction of it is sometimes used in *dropsy;* and the same preparation, as well as an ointment prepared with the fresh bark, is employed in treating the *itch.*

FRASERA, *U. S.*—AMERICAN COLUMBO.

Radix fraseræ, Radix columbo americanæ.—Racine de colombo de Mariette (d'Amérique,) Fr.; *Fraserawurzel, Amerikanische Columbowurzel,* G.

The root of Frasera Walteri, *Mich.* (Fr. Caroliniensis, *Walt.*).

Nat. Ord.—Gentianaceæ.

Origin.—This is a tall biennial or triennial herbaceous plant, indigenous to the United States, where it grows in rich and moist soil west of the Allegheny Mountains, from New York southward, and in the Southern States. The plant is smooth, 5 to 10 feet high; the leaves are in whorls of about 6, sessile, entire, oblong, and parallel veined. The yellowish white flowers form a large pyramidal panicle, and bear a large roundish gland in the middle of each corolla lobe; the fruit is a flattened capsule containing several seeds. The root should be collected in the autumn of the second year.

Description.—In general aspect American colombo resembles gentian root, except that it is of a lighter and more distinctly yellow color internally, and of a light orange-brown externally. When dried in transverse slices, the outer layer of the bark projects above the shrunken tissue of the fleshy central portion, and this with the yellow tint gives it a faint resemblance to colombo, from which it is easily distinguished by the absence of the projecting vascular bundles in the interior, and of the radiating zone near the cambium. It is now generally dried in longitudinal slices, the bark overlapping. The tissue upon transverse section is pretty uniform in appearance, the woodbundles being nearly imperceptible in the fleshy parenchyma; the rather thick bark shows two different colored layers, and a dark brown cambium line separates it from the meditullium. When dry it has a slight odor; the odor of the infusion is similar to that of gentian; the taste is sweet and bitter, and free from astringency and aroma.

Constituents.—Frasera root was analyzed by J. W. Douglass (1840), W. R. Higinbotham (1857), and F. W. Thomas (1868), who proved the absence of starch, and the presence of pectinaceous and saccharine compounds in it. Douglass noticed the dark coloration produced in the infusion by ferric salts, and attributed it to tannin. G. W. Kennedy (1873) obtained from the root *gentisic acid* and *gentiopicrin.* American colombo is, therefore, very closely analogous to gentian, from which it appears to differ, chemically, in containing more of the yellow acid and less of the bitter principle than the latter.

Medical Action and Uses.—When fresh it is said to have emetic and purgative properties, and has been compared in its action to rhubarb. The dried root is reputed to have the tonic properties of simple bitters, and may be given in an infusion made with an ounce of the root to a pint of boiling water. *Dose,* one or two fluidounces.

FRAXINUS.—EUROPEAN ASH.

Frêne, Fr.; *Esche,* G.

Fraxinus excelsior, *Lin.* *Nat. Ord.*—Oleaceæ, Fraxineæ.

Description.—The European Ash, which is sometimes cultivated in the United States as a shade tree, attains a height of 120 to 150 feet, has a straight trunk, the flowers polygamous, without calyx or corolla, in lax racemes, and produces a two-celled one-seeded fruit, the apex of which is extended into a long many-nerved wing. *The bark,* which is collected from the branches in spring, is in quills, having a gray or greenish-gray color externally, numerous small gray or brownish-white suberous warts, and a smooth inner surface of a yellowish or yellowish-brown color. It is inodorous, has a bitter, astringent taste, and breaks with a smooth, and in the inner layer, fibrous fracture. *The leaves* are pinnate, composed of 11 or 13 nearly sessile leaflets, which are almost smooth, 2 or 3 inches long, vary in shape between elliptic-oblong and oblong-lanceolate, have a wedge-shaped and entire base, and are sharply serrate above.

Constituents.—The bark contains tannin, the bitter glucoside *fraxin* (see Hippocastanum), and a crystalline principle obtained by Keller by a process similar to that by which salicin may be obtained; it was at first named *fraxinin*, but was recognized as mannit by Stenhouse and Rochleder.

Garot (1853) found in the leaves malate of calcium; Mouchon's *fraxinit* is extract-like, and said to be purgative.

Medical Action and Uses.—No accurate description of the operation of this medicine has been published. Infusions of the leaves are said to be either diaphoretic or diuretic. The bark at one time enjoyed a certain vogue in Europe as a remedy for *intermittent fever*, and there seems to be no doubt that it was often used with success in cases which had proved rebellious to cinchona, so that it may be included in the large class of succedanea for Peruvian bark and its derivatives. The leaves are more or less purgative, and are said to operate like senna; but their more important use appears to have been in the treatment of *gout*. There seems to be conclusive evidence of their efficacy when administered in an infusion made with thirty grains of the leaves in half a pint of water, strained and sweetened, and taken twice or thrice daily. A similar method is reported to be successful in *articular rheumatism*. According to Pliny, serpents will avoid even the shadow of the ash, and he affirms as of his own knowledge that if a snake is inclosed in a circle of ash leaves in the centre of which are burning coals, it will plunge into the fire rather than touch the leaves. A similar fact or superstition exists in regard to the white ash (F. Americana). On the land where it grows no rattlesnake will be found; "and it is the practice of hunters and others having occasion to traverse the woods in the summer months to stuff their boots or shoes with white ash leaves as a preventive of the bite of the rattlesnake." We have several times known this precaution to be taken with full faith in its efficacy.

FUCUS VESICULOSUS, *Lin.*—BLADDER-WRACK.

Quercus marina.—*Sea wrack*, *Kelp-ware*, *Blacktang*, E.; *Fucus* (*Varech*) *vésiculeux*, Fr.; *Blasentang*, G.

Nat. Ord.—Algæ, Fucoideæ.

Description.—It grows on rocky shores of the Atlantic Ocean, attains a length of 2 or 3 feet, and has a flat branching thallus, ½ to 1 inch wide, with the margin entire, and a distinct midrib through its entire length. The vesicles are usually in pairs, separated by the midrib, spherical or oblong in shape, and occasionally attaining the size of a hazel-nut. In the fresh state it is of a brownish-green color, which becomes nearly black on drying. It has the peculiar odor of seaweeds, and a mucilaginous and saline taste.

Allied Species.—FUCUS NODOSUS, *Lin.*, is 4 to 6 feet long, and has a narrower frond or thallus without midrib, and with single vesicles, which are ovate or oblong, and usually large.

FUCUS SERRATUS, *Lin.*, has a veined and serrate frond without vesicles.

FUCUS SILIQUOSUS *Lin.*, s. Cystoseira siliquosa, *Agardh.* The frond is very narrow, 2 to 4 feet long, with short branches, articulated vesicles, and lanceolate flattened sporocarps.

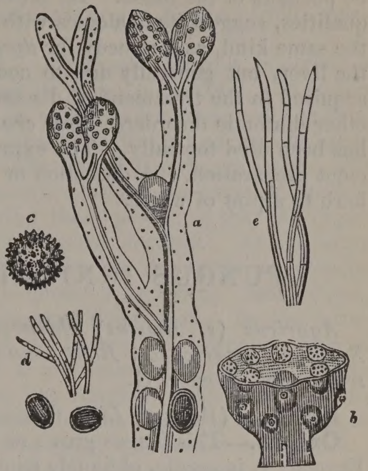
FUCUS NATANS, *Lin.*, s. Sargassum bacciferum, *Agardh*, is the *Gulf-weed* of the Atlantic Ocean, and is often found in immense masses floating in the sea.

The frond is terete, has linear and serrate branches, and globular aculeate vesicles.

Constituents.—These plants are very similar in composition. They contain mucilage, mannit, odorous oil, a bitter principle, and between 14 and 20 per cent. of ash calculated for the dried plant. Gödeschen, James, and others, found the mineral constituents of the bladder-wrack, as collected from different places, to vary to the same extent. Marchand (1865) obtained from the ash of the bladder-wrack 0.719 per cent. of iodine and 0.603 of bromine; from F. vesiculosus nearly the same amount; and from F. serratus 0.834 iodine, and 1.007 bromine.

Medical Action and Uses.—The medicinal virtues of this product depend apparently upon the iodine and bromine which it contains in common with other species of seaweed. It has been applied externally, bruised, to enlarged *scrofulous* glands, and internally it was at one time recommended as a means of lessening *obesity*. It was administered chiefly in a decoction made with from two to four drachms of the plant in a pint of water, and was alleged not to occasion atrophy of the mammæ or testes, while it reduced the fat in a notable degree. For this purpose it had a brief vogue, but is now almost forgotten.

Fig. 77.



Fucus vesiculosus, *Lin.*—*b*, section of a receptacle; *c*, conceptacle; *d* and *e*, filaments and spores.

FUMARIA.—FUMITORY.

Fumeterre, Fr.; *Erdrauch*, *Feldraute*, G.

Fumaria officinalis, *Lin.* *Nat. Ord.*—Fumariaceæ.

Description.—Fumitory is a low annual about twelve inches high, which is common in the fields throughout Europe, and more or less naturalized in most civilized countries. The entire plant is of a glaucous gray-green color; the stem is angular and much branched; the leaves are alternate, finely dissected compound, with spatulate or obovate-oblong, rather acute lobes; the flowers are in terminal and axillary racemes, have acute and sharply-toothed sepals, and a pale red and crimson or purplish corolla which is one-spurred at the base. The fresh plant has a somewhat heavy odor, and a saline, bitter, and rather acrid taste.

Constituents.—Winkler (1831) isolated *fumaric acid*, $C_4H_4O_4$, which had been obtained by Lassaigne (1819) from malic acid, $C_4H_6O_5$; the latter heated to 150° C. (302° F.) is almost completely resolved into fumaric acid and water. Fumaric acid crystallizes in colorless prisms, volatilizes partly unaltered above 200° C. (392° F.), and, when heated with hydriodic acid, or under the influence of nascent hydrogen, is converted into succinic acid. Peschier discovered the alkaloid *fumarina*. Pommier (1853) obtained it by exhausting the fresh herb with water acidulated with acetic acid, and precipitating with ammonia. It is white, crystalline, bitter, not freely soluble in water, but soluble in alcohol. The analysis of Merck proved the presence of the usual constituents of herbs.

Medical Action and Uses.—This is one of many medicines reputed to be purifiers of the blood. Its bitter taste, and its slightly laxative and diuretic qualities, suggest its analogies with dandelion. Its reputation, also, is partly of the same kind, as a remedy for *dyspeptic* derangements attributed to torpor of the liver, but generally due to constipation. But its greatest credit has been acquired in the treatment of diseases of the *skin* depending on scrofulous and other diathetic disorders. For *crusta lactea* a decoction of the plant in milk has been used topically. The expressed juice of the fresh plant is its most efficient preparation. A decoction or infusion may be made with an ounce of the herb to a pint of water.

FUNGUS IGNIARIUS PRÆPARATUS, *P. G.*

Agaricus (s. Boletus) chirurgorum s. igniarius.—*Spunk, Touchwood, Surgeon's agaric,* E.; *Bolet amadouvier, Amadou non-salpêtré,* Fr.; *Feuerschwamm, Zunder,* G.

Polyporus (Boletus, *Lin.*) fomentarius, *Fries.* *Nat. Ord.*—Fungi.

Origin.—This fungus grows on beech and oak trees in Southern and Middle Europe; it is sessile, obliquely triangular, brown-gray externally, and yellowish-brown internally. The hard rind is removed, and the fungus cut into thin slices, which are soaked in water, boiled in weak lye, washed, and beaten with mallets until soft. It is then ready for surgical purposes. For use as tinder it is soaked in a saturated solution of nitrate of potassium.

Description.—Surgeon's agaric is in thin, flat pieces, tasteless, of a faint odor, and rust-brown color, somewhat glossy, very soft and velvety.

Polyporus igniarius and *marginatus*, Lin., yield a similar but harder product.

Surgical Action and Uses.—On account of its combined lightness, elasticity, toughness, and porosity, this substance has long been used to arrest *hemorrhage* from slight wounds, and especially from leech-bites. It should be secured in its place by a bandage or other pressure. When prepared with nitrate or with chlorate of potassium it may be formed into cylinders and used as a *moxa.* Its physical qualities give it a superiority over all other substances to be insinuated between the ulcerated skin and an *ingrown toe-nail.* The success of this treatment depends upon preventing any movement of the parts by means of a narrow strip of adhesive plaster wound around the toe.

FUNGUS MUSCARIUS.

Fly fungus, Fly agaric, E.; *Agaric mouche, Fausse oronge,* Fr.; *Fliegenschwamm,* G.

Amanita muscaria, *Pers.*, s. Agaricus muscarius, *Lin.* *Nat. Ord.*—Fungi.

Origin.—This European fungus grows in autumn chiefly under pine trees; allied poisonous species are met with in most countries. Some species of the same genus are edible.

Description.—The stalk is three to six inches high, and about three-quarters of an inch thick, white. The cap (pileus) is flattish or convex, scarlet or orange-red, more or less covered with white warts, and on the under side with white lamellate gills (hymenium). It has a disagreeable odor, and a burning, acrid taste. Infused with milk, it is used for poisoning flies; hence the name.

Constituents.—The poisonous principle, according to Apoiger (1851), is a crystallizable acid, soluble in ether, and precipitated by acetate of lead. Leteiller (1866) called it *amanitin*, which is brown, amorphous, tasteless, insoluble in ether, soluble in water, and not precipitated by lead salts or gallic acid.

Sicard and Schoras (1865) announced that various toadstools contain a poisonous volatile alkaloid; the volatile alkaloid obtained by Apoiger had a very disagreeable odor, but was not poisonous. Schmiedeberg and Koppe (1869) separated a poisonous alkaloid *muscarina.*

Physiological Action. *On Animals.*—After subcutaneous injection of muscarina in a frog, the heart loses by degrees its power to contract, and at last stands still in diastole. Although it cannot be stimulated mechanically to contract, its power may be restored by atropia, daturia, digitalin, and various other agents. If the animal be already under the influence of atropia, muscarina will not produce its characteristic effects. In mammals large doses increase the frequency of the heart's pulsations while limiting their power, so that the organ grows more and more dilated, and the blood-pressure declines. At the same time, as might be anticipated, the blood accumulates in the lungs and venous system, causing more or less cyanosis, with symptoms of asphyxia. Small doses, on the other hand, quicken without embarrassing respiration. In the latter cases the temperature is somewhat raised; in the former it is lowered. One of the most constant effects is salivation, which is proportioned to the dose administered, sometimes vomiting, tardy diarrhœa, but frequent defecation and increased secretion of urine. The peristaltic action of the bowels is sometimes so vigorous as to be visible through the skin. The pupil is generally contracted.

On Man.—In large doses it occasions violent and fatal symptoms.

A case is on record in which several soldiers who had eaten of this fungus presented the following phenomena: anxiety, burning thirst, oppressed breathing, severe colic, a small and irregular pulse, cold sweats, sunken features, with a cyanotic hue of the nose, lips, hands, and feet; general twitching of the muscles, distension of the abdomen, fetid evacuations from the bowels, delirium, and great anguish until death. It is employed by many Siberian tribes to produce excitement and inebriation; and it imparts to the urine an intoxicating quality which continues for a considerable time after taking it. "A man, for example, may have intoxicated himself to-day by eating some of the fungus; by the next morning he will have slept himself sober; but by drinking a teacupful of his urine he will become as powerfully intoxicated as the preceding day." (Pereira.)

A very interesting case of poisoning by this fungus, which occurred at Calcutta, is related by Dr. Chevers. An accomplished gentleman, of temperate habits, having partaken of some mushrooms at breakfast, went to court, and was surprised to find that he could not control his actions; every thing and person appeared to him ludicrous; he laughed immoderately in open court, and ridiculed, in an absurd way, his superior officer. After some hours he recovered, but was naturally alarmed at his attack, of which he did not suspect the cause. His physician, to console him, promised to return to luncheon, at which, among other dishes, were stewed mushrooms. Of these he ate, and before the meal was finished he became very much excited; every person appeared ridiculous; the most ordinary remark seemed full of fun and wit, and his laughter was immoderate. Every object appeared to him perfectly beautiful. These exaggerated sensations continued for some hours, and were put an end to by the administration of ipecacuanha, which caused him to disgorge a considerable quantity of the fungi still undigested. No after ill effects were experienced. It will be observed that in this narrative there is absolutely nothing to suggest, or to be explained by, the results of the physiological experiments above described. But in the fatal cases above referred to, the cyanotic phenomena correspond to the effects produced in animals by lethal doses of muscaria.

Medical Uses.—At one time this fungus had a doubtful reputation for the cure of *epilepsy;* but it is no longer used in medicine.

GALANGA.—GALANGAL.

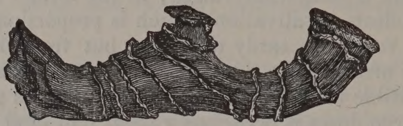
Radix galangæ minoris.—*Galanga*, Fr.; *Galgant*, G.

The rhizome of Alpinia officinarum, *Hance.* *Nat. Ord.*—Zingiberaceæ.

Origin.—The galangal plant resembles a flag, has stems about 4 feet high, and white flowers, veined with red, in terminal racemes. It is indigenous to the island of Hainan in the south of China, and probably also to the adjacent mainland.

Description.—The rhizome appears in commerce in sections about 2 inches long, $\frac{1}{4}$ to $\frac{1}{2}$ inch in diameter, frequently with 1 or 2 short branches. It has externally a rust-brown color, is longitudinally striate, and transversely marked with the short remnants of the leaf sheaths. It is rather tough, breaks with a somewhat fibrous fracture, is internally grayish-brown, and on a transverse section shows the nucleus sheath as a dark-colored circular line, and the tissue containing scattered oil-cells and wood-bundles, the latter being more numerous in the central portion. Galangal has an agreeable aromatic odor, which becomes more prominent on bruising the rhizome, and a pungent taste, somewhat resembling that of ginger.

Fig. 78.



Galangal.

Constituents.—Galangal contains about one-half per cent. of a pale-yellow or brownish-yellow volatile oil, which is lighter than water, and, according to Vogel (1844) has the composition $C_{10}H_{18}O$. The water distilled from galangal contains ammonium carbonate (Vogel). The pungent taste of the rhizome, according to Bucholz, is due to a soft resin which has not been further examined. Brandes (1839) obtained by means of ether a brown oleoresin containing crystals of *kæmpferid*, which, when pure, are yellowish, pearly, tasteless, and inodorous, and are colored by sulphuric acid first yellow, afterwards dark green.

Allied Drug.—ALPINIA GALANGA, *Willd.*, of Java, yields the *greater galangal*, *radix galangæ majoris*, which is rarely seen in our commerce. It is longer and thicker than the preceding, externally brown-red, internally grayish or buff colored.

Medical Action and Uses.—Galangal is an aromatic and, therefore, a local and general stimulant, resembling ginger in its qualities and effects. It was formerly held in high repute as a stomachic for promoting *digestion* and relieving *flatulence.* It was also employed for correcting nausea and preventing *vomiting* due to indigestible food, and also occurring as symptoms of febrile diseases of a typhoid type. Its somewhat acrid taste renders it unsuitable for administration in powder, which may, however, be prescribed in the *dose* of twenty or thirty grains. It is preferably given in an infusion made with an ounce of the bruised root to a pint of water. A tincture is also employed in the *dose* of a fluidrachm.

GALBANUM, *U. S.*, *Br.*—GALBANUM.

Gummi-resina galbanum.—*Galbanum*, Fr.; *Mutterharz*, *Galban*, G.

The gum-resin obtained from Ferula galbaniflua, *Boiss. and Buhse.* Bentley and Trimen, Med. Plants, 128.

Nat. Ord.—Umbelliferæ, Orthospermæ.

Origin.—This plant is indigenous to Northern Persia. The stem is 4 or 5 feet high; the radical leaves are large, triangular, decompound pinnate, and pinnatifid, with the ultimate sections linear and obtuse; the stem-leaves are small; the fruit is somewhat winged near the face of the mericarps, the ribs are prominent and slender, and the oil-tubes solitary in each groove, and absent in the commissure or often there are two narrow ones. The plant, with the one noticed below, was originally (1844) described by Boissier under the name of *Fer. erubescens*, subsequently (1856) as *F. gummosa.*

Fer. rubricaulis, Boiss., grows in Southern, and, probably, also in Northern Persia, and has the leaves with wider segments and the oil-tubes narrower and more numerous than the preceding. *Fer. Schair*, Borszczow, a native of the Khirgise country, yields also a gum-resin similar to galbanum, which, however, does not appear to be collected. The gum-resin exudes spontaneously, and, as far as known, no incisions are made to promote the exudation. It enters commerce chiefly through Russia and from the Levant.

Description.—The best quality of galbanum is met with in tears, varying in size from a pin's head to a pea and larger; sometimes it is soft and semifluid. The tears adhere to one another, forming a more or less compact mass; they are of a reddish-, brownish-, or greenish-yellow color externally, internally white or yellowish, with a waxy gloss, and are somewhat translucent. It has a peculiar, unpleasant, balsamic odor, and a disagreeable, bitter, and acrid taste. Moistened with alcohol, a fine purplish color will be produced on the addition of a little strong muriatic or nitric acid.

Lump galbanum consists sometimes of soft or harder masses, in which some tears are distinctly observed; sometimes a mass is offered, which, from its odor and behavior, seems to be of a different origin.

Constituents.—According to the older analyses by Neumann, Pelletier, and others, galbanum contains 6 to 6.5 per cent. of volatile oil, 20 per cent. of gummy matter, and 60 to 66 per cent. of resin, besides 7 to 14 per cent. of impurities. The *volatile oil* is colorless, turns yellowish and thick on exposure, varies in specific gravity between .88 and .92, has the boiling point 160° to 165° C. (320° to 329° F.), is dextrogyre, and of the composition $C_{10}H_{16}$. The resin is yellowish-brown, soluble in ether, alcohol, and alkalies. On being heated it yields a beautiful indigo-blue volatile oil, which, according to Kachler (1871), consists of a colorless oil, $C_{10}H_{16}$, boiling at 240° C. (464° F.), and of a deep-blue oil, $C_{30}H_{48}O_3$, which boils at 281° C. (538° F.), appears to be identical with the blue portion of the oil of German chamomile, and yields with potassium a hydrocarbon, $C_{30}H_{48}$, the solution of which in much aqueous ether gives with an ethereal solution of bromine an azure-blue color, changing to green and brown. Galbanum resin, treated with fusing potassa, yields several volatile fatty acids, and *resorcin*, the solution of which is colored dark purple by ferric chloride (Hlasiwetz and Barth, 1864).

An aqueous infusion of galbanum, on the addition of ammonia, assumes a blue fluorescence, which disappears again on the addition of an acid. This reaction is due to *umbelliferon*, $C_9H_6O_3$, which may be obtained in colorless needles by heating galbanum with muriatic acid to 100° C. (212° F.), agitating the liquid with ether or chloroform, and evaporating the latter solution. Volatile fatty acids were also found by Moessmer (1861) in the emulsion remaining after distilling off the volatile oil.

Off. Prep.—Emplastrum assafœtidæ, *U. S.;* Empl. galbani, *Br.;* Empl. galbani comp., *U. S.;* Pilula assafœtidæ comp., *Br.;* Pil. galbani comp., *U. S.*

Medical Action and Uses.—Galbanum is generally described as partaking of the virtues both of asafœtida and ammoniac, affecting the nervous system like the former, and acting, like the latter, as a local irritant. Applied to the skin it occasions a papular eruption, and, if the true skin is exposed, causes it to ulcerate. Upon the system generally it probably acts as a stimulant, for in large doses it is said to cause fulness of the head and tension of the pulse. Moreover, its therapeutical virtues are limited to cases that call for stimulation; these are such as the resins and gum-resins are applicable to, and especially *chronic bronchitis, chronic intestinal, uterine, and vaginal catarrh, amenorrhœa,* etc. It is seldom given alone, and hence virtues are apt to be attributed to it that belong to its associated medicines. Thus, in the compound galbanum pill it is united with asafœtida and myrrh. Even for external use it is associated with other irritants (see Emp. galbanum comp.). The *dose* of galbanum is from five to twenty grains. It is best administered in emulsion.

GALEGA.—GOAT'S RUE.

Galega, Rue de chèvre, Fr.; *Geisraute,* G.

Galega officinalis, *Lin.* *Nat. Ord.*—Leguminosæ, Papilionaceæ.

Description.—Goat's rue is found in the countries bordering on the Mediterranean and northward to Central Europe. It has a perennial several-headed root, and an erect stem about 3 feet high; the leaves are furnished with 6 or 8 pairs of lanceolate or ovate-lanceolate, obtuse, and finely muronate leaflets 1 or 2 inches long, and with lanceolate stipules, which are sagittate on one side. The purplish or whitish flowers are in axillary racemes, and produce narrow, almost cylindrical, legumes. The herb is inodorous, and has a mucilaginous and somewhat bitter taste. Its constituents are unknown.

Medical Action and Uses.—Galega was at one time held to be diaphoretic, diuretic, and anthelmintic, and was used as a stimulant in nervous affections of an *hysterical* or *spasmodic* nature, in low *fevers,* and especially in the *plague.* It is said, also, to favor the *mammary secretion.* A native species, G. Virginiana, is said to possess analogous qualities. In Europe galega is no longer used, except in domestic medicine.

GALIUM.—CLEAVERS.

Bedstraw, E.; *Caille-lait, Gallait,* Fr.; *Labkraut,* G.

Nat. Ord.—Rubiaceæ, Stellatæ.

Description.—The following species have been used:—

GALIUM APARINE, *Lin.*, Cleavers, *E.;* Grateron, Rièble, *Fr.;* Klebkraut, *G.* It grows in thickets in North America, Europe, and Northern Asia, has a weak, retrorsely prickly, quadrangular stem, 3 or 4 feet long; linear-lanceolate and mucronate leaves in whorls of 6 or 8, which are prickly roughened on the mid-rib and margin; small whitish flowers and fruits composed of two united one-seeded carpels, which are armed with hooked prickles.

G. TRIFLORUM, *Mich.*, Sweet-scented bedstraw, *E.* It is indigenous to North America, resembles the preceding, but has elliptic-lanceolate slightly rough leaves in whorls of six, three-flowered peduncles, and acquires an agreeable odor on drying.

G. MOLLUGO, *Lin.*, indigenous to Europe, somewhat naturalized in the United

States, has a smooth stem, oblanceolate or oblong-linear, somewhat rough leaves in whorls of 8, and long panicles of whitish flowers yielding smooth fruits.

G. VERUM, *Lin.*, with whorls of 8 linear leaves, compact panicles of yellow flowers and smooth fruits, is a European plant, sparingly naturalized in the United States.

Constituents.—The plants contain either *galitannic* or *aspertannic acid*, both producing green precipitates with iron salts. They likewise contain *citric*, *oxalic*, and *rubichloric acids*, a bitter principle and the common principles of herbs (R. Schwarz, Vielguth). Von Cotzhausen (1876) determined the odorous principle of Galium triflorum to be *coumarin*, to which is also due the agreeable odor of the nearly allied Asperula odorata, *Lin.*, known in France as *aspérule odorante*, and in Germany as *Waldmeister.* The roots of several species of Galium contain red coloring matter resembling that of the allied Rubia tinctorum, *Lin.*

Medical Action and Uses.—This plant has been used in Europe chiefly as a diuretic in *dropsy*, and in *jaundice*, and in treating *scaly skin diseases*, especially of a *scrofulous* nature. It has even been alleged to cure *epilepsy* and *cancer* of the tongue. Notwithstanding the virtues attributed to it at various times, it does not seem to have established its claims to confidence.

GALLA, *U. S.*, *Br.*—NUTGALL.

Gallæ, P. G.; *Galla halepense, vel turcica, vel levantica, vel tinctoria, vel quercina.—Galls*, E.; *Noix de galle, Galle de chêne*, Fr.; *Galläpfel*, G.

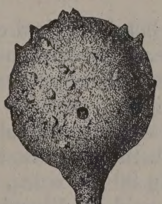
Excrescences on Quercus infectoria, *Olivier*, s. Q. lusitanica, *Webb*, var. infectoria, caused by the punctures and deposited ova of Cynips (Diplolepis, *Latr.*), gallæ tinctoriæ, *Oliv.* Steph. and Church, Med. Bot., plate 152.

Nat. Ord.—Cupuliferæ.

Origin.—The dyer's oak is a small tree, or oftener a shrub 4 to 6 feet high, and is found in the eastern section of the Mediterranean basin from Greece to Persia. The tender bark of the young branches is punctured by the female of the hymenopterous insect named above, and one or more eggs are deposited in the wound. The irritation produced by this operation causes the formation of an excrescence inclosing the larva, which undergoes therein its transformations. The term *gall* is generally used to designate such excrescences formed upon any part of a plant, in consequence of the puncture of an insect.

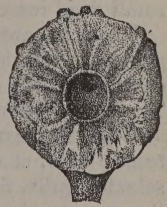
Description.—Nutgalls are nearly globular, about an inch or less in diameter, with a short stipe or a nearly smooth surface or, more frequently, more or less tuberculated in the upper portion. Their color externally is a deep blackish olive-green, which, if the gall remains upon the branch, gradually becomes lighter, and finally of a light yellowish-brown tint, their weight decreasing at the same time. Galls are hard, but are readily broken with a hammer, exhibiting a more or less dense granular fracture which has sometimes a waxy lustre. Internally, they are yellowish or pale brownish-gray, with a central nucleus or cavity, containing either the more or less fully developed insect, or pulverulent fragments of the cellular tissue. In the latter case, the insect has usually escaped through a cylindrical canal which it has bored from the cavity to the surface, the outer aperture being near the middle. The cellular tissue of the nucleus, if still pre-

Fig. 79.



Entire.

Fig. 80.



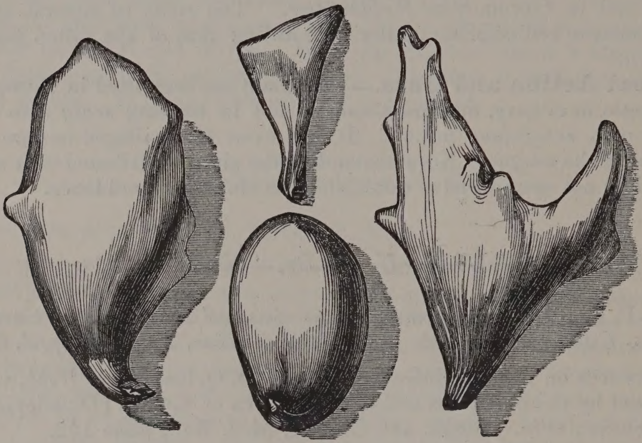
Section.

Nutgall.

sent, is mostly filled with small starch granules, and surrounded by a layer of thickened cells forming a shell, on the outside of which is the cellular tissue containing the tannin. This tissue has often a radiated appearance near the shell, and contains towards the surface small scattered bundles of vascular tissue. Nutgalls are nearly inodorous and have a very astringent taste.

Nutgalls are distinguished in commerce according to their color, the *blue* or *black galls*, of Syria (Aleppo), being preferred. *Smyrna galls* are usually of grayish olive-green, more spongy in texture, and intermixed with *white galls;* the latter are the least valuable. The galls which are produced upon the European and American oaks by different species of Cynips, are mostly of a lighter color and more spongy texture; but all have an astringent taste and contain tannin.

Fig. 81.



Chinese Nutgalls.

Allied Drugs.—CHINESE AND JAPANESE GALLS, although known from a much earlier period, were not a regular article of commerce until Pereira (1844) directed attention to them again. They are produced upon the leaves or leaf-stalks of *Rhus semialata*, Murr., by an insect provisionally named Aphis Chinensis. They are of a very irregular shape, usually thin as if stalked towards the base, much inflated above, irregularly lobed, and with few or many protuberances; they are of a reddish-brown color, but densely covered with a gray down, consist of a thin fragile shell, and contain in the interior numerous small dead insects.

VALONIA are the hemispherical cups of Quercus ægilops, *Lin.*, which is indigenous to Southeastern Europe and the Levant. They are about an inch in diameter, have thick spreading scales, and possess a strongly astringent taste. The cups of our indigenous species are likewise astringent.

Constituents.—The principal constituent of nutgalls is *tannin* or *gallotannic acid*, of which they contain about 60 per cent. Bowman (1869) assayed selected galls, finding 80 per cent., and in white galls only 30.7 per cent. 2 or 3 per cent. of gallic acid are likewise found, together with some sugar, resinous, and albuminous matter, and, as stated before, starch in the nucleus.

Pharmaceutical Uses.—In the preparation of tannic and gallic acids, and for Tinct. gallæ, Unguent. gallæ, *U. S.*, *Br.*, and Unguent. gallæ cum opio, *Br.*

Medical Action and Uses.—From the most ancient times, nutgall has been used in medicine for its astringency. This property is due to gallotannic acid, but the bitter extractive principle of nutgall gives it a tonic action. These qualities account for its efficacy in the treatment of chronic *diarrhœa.* It has been used as an *antidote* to tartar emetic and the vegetable alkaloids; and whatever degree of efficacy it then exerts is probably due to its constringing the stomach and delaying the absorption of its contents. An infusion made with from half an ounce to an ounce of coarsely powdered nutgall in a pint of boiling water, may be given in the dose of a wineglassful three or four times a day, for the purposes referred to; and it may be locally applied to the relaxed mucous membrane of the mouth, throat, vagina, and rectum. An ointment of nutgall is officinal.

GAMBOGIA, *U. S.*—GAMBOGE.

Cambogia, Br.; *Gutti*, P.G.; *Gummi-resina* (*Gummi*) *guttæ, s. gutti, Gutta gamba, Cambodia.—Gutte, Gomme-gutte*, Fr.; *Gummigutt, Gutti*, G.

A gum-resin obtained from Garcinia Hanburii, *Hook. f.* Bentley and Trimen, Med. Plants, 33.

Nat. Ord.—Guttiferæ.

Origin.—A medium-sized tree, with glossy laurel-like leaves, and small yellow diœcious flowers, the pistillate ones being on short pedicels. It was formerly regarded merely as a variety, *pedicellata* of Garc. morella, *Desrousseaux* (s. G. gutta, *Wight;* G. cambogioides, *Royle;* Hebradendron cambogioides, *Graham*), and is indigenous to Siam, Cambodia, and Cochin China. Flückiger and Hanbury observed that the milky juice is secreted in ducts, which are principally located in the middle bark, and to a less extent in the dotted vessels of the alburnum and in the pith. Gamboge is obtained from incisions made into the bark, the yellow latex being collected in the joint of a bamboo, where it is allowed to harden.

Description.—Gamboge is in cylindrical straight or bent sticks, 6 to 8 inches long and 1 to 2 inches in diameter, called pipes; the surface is striated longitudinally from impressions of the bamboo, and occasionally contains some splinters of it. Gamboge breaks easily, with a flattish conchoidal, smooth fracture, of a deep orange-red tint and a resinous lustre; thin splinters are slightly translucent. It yields a light yellow powder, and on being triturated with water a uniform bright yellow emulsion is readily obtained. It is inodorous, but the dust is sternutatory, and it has a disagreeable acrid taste. Inferior qualities of pipe gamboge are of a brown or gray tint, harder, of a dull earthy or irregular fracture, and less inclined to produce a uniform emulsion.

Cake gamboge has been collected in flat vessels, and is met with in irregular lumps, which otherwise resemble pipe gamboge, but are more liable to be adulterated.

Constituents.—Aside from accidental impurities, like cellular tissue, gamboge contains about 4 per cent. of moisture, the remainder being resin and 16 to 20 per cent. of gummy matter which is not identical with gum arabic. The resin is called *cambogic acid*, is soluble in alcohol, ether, and with a deep red color in dilute alkalies, and from the latter solution is precipitated unaltered by acids; its solutions yield a yellow precipitate with lead acetate, and brown ones with iron and copper salts. By fusing it with caustic potassa, Hlasiwetz and Barth (1866) observed the disengagement of vapors having the odor of lemon and melissa, and found in the residue, besides acetic and volatile fatty acids, also *phloroglucin, pyrotartaric* and two other acids. Gamboge is free from starch, and, if adulterated with it, an emulsion made with hot water will turn green by solution of iodine; or it may be recognized in the residue left after treatment with alcohol and cold water.

Off. Prep.—Pilulæ catharticæ comp., *U. S.;* Pil. cambogiæ comp., *Br.*

Physiological Action.—Experiments upon animals with gamboge do not render its operation clear. It produces few symptoms of local irritation, but little evidence of pain, fever, nervous motor derangement, or coma; and not uniformly either vomiting or purging. In man, applied to the raw skin, it acts as an irritant. Internally, in small doses, it appears to increase the glandular secretions; but in large doses causes colic and tenesmus. In doses of three or four grains it occasions liquid stools, with little or no colic. Its purgative virtue appears to reside in its resinous element. When given in small and repeated doses, it is said to cause diuresis. There is no evidence of its having ever produced fatal effects.

Medical Uses.—Gamboge is seldom employed, unless associated with other purgatives. It is reputed to be well adapted for relieving such congested states of the *liver* as arise from malarial causes. In these cases it is usually associated with calomel. As a *hydragogue*, acting by the kidneys as well as the bowels, its merits appear to be well established. For this purpose it should be given in small and repeated doses, such as a grain every hour, dissolved in sweetened water. It is often associated with jalap and with bitartrate of potassium. Its want of taste fits it for use by children. It is sometimes employed as a *vermifuge;* but for this purpose is best administered along with vermicide medicines.

Gamboge is administered in substance, in the average *dose* of from one to five grains. It is most efficient when given mixed with water and sugar. A convenient formula is the following: ℞. Gamboge, gr. x; Carbonate of potassium, ʒj; Cinnamon water, f℥ij.—Mix. S.—Thirty drops three times a day, in water.

GAULTHERIA, *U. S.*—GAULTHERIA.

Folia gaultheriæ.—Wintergreen, Teaberry, Partridgeberry, Boxberry, Checkerberry, E.; *Feuilles de gaulthérie (de palommier), Thé du Canada, Thé de Terre-neuve,* Fr.; *Canadischer Thee, Bergthee,* G.

The leaves of Gaultheria procumbens, *Lin.* (s. G. humilis, *Salisb.;* Gaultiera repens, *Rafin.*). Bigelow, Med. Bot., t. 22; Bentley and Trimen, Med. Plants, 164.

Nat. Ord.—Ericaceæ, Ericineæ.

Origin.—Teaberry is found in cool damp woods, usually in the shade of evergreens, in Canada and the United States. The plant is a small shrub, with a slender creeping stem and ascending branches, about 5 inches high, bearing the alternate evergreen leaves near the summit, axillary, nodding, whitish flowers, and 5-celled berry-like pods, which are inclosed in the bright-red fleshy calyx. The leaves are collected late in summer or in autumn.

Description.—The leaves are short petiolate, about 1½ inch long and ¾ to 1 inch wide, obovate or roundish-oval in shape, with a wedge-shaped base, coriaceous in texture, mucronate and slightly toothed, the teeth having the elongated points appressed to the thickish margin; they are smooth, of a glossy green color above, and paler beneath. The odor is agreeably aromatic, the taste astringent and aromatic.

Constituents.—We are not acquainted with a complete analysis of the leaves. They contain a volatile oil (see *Oleum gaultheriæ*) and tannin. Jefferson Oxley (1872) found, besides grape sugar, gum, coloring matter, and a principle analogous to gallic acid, *arbutin, urson,* and *ericolin,* principles which are likewise present in the leaves of Chimaphila and in Uva ursi.

Medical Action and Uses.—Gaultheria is stimulant and somewhat astringent. It has sometimes been employed as a substitute for Chinese tea in country places, where it is also popularly used as an *emmenagogue* and *galactagogue,* and in chronic *bowel complaints.* In the former cases a hot infusion of the leaves is best; in the latter a cold infusion.

GELATINA.—GELATIN.

Gelatine, Fr.; *Gelatin*, G.

Origin and Preparation.—When bone-cartilage, animal skin, tendons, and ligaments, are boiled for a long time with water, they become soluble therein, and, on cooling, the solution forms a jelly. During the boiling the animal tissues are placed upon a sieve, or perforated diaphragm, which is inserted above the bottom of the boiler. When sufficiently saturated, the solution is drawn off, and allowed to cool, the jelly being then cut into thin cakes, and these are placed upon nettings to dry. When made from carefully selected material (fresh bones) it constitutes the *gelatin* of commerce, known also as *artificial isinglass*. The offal of slaughter-houses and of tanneries yields an impurer gelatin, known as *colla*, s. *colla animalis*, s. *glutinum;* glue, *E.;* colle, colle forte, *Fr.;* Leim, *G.* The United States import annually about 150,000 lbs. of gelatin.

Properties.—Gelatin is met with in commerce in very thin, rectangular, transparent pieces, bearing the impressions of the netting upon which it has been dried; or in smooth sheets, which are either thin and transparent, or thicker, more or less porous and opaque. It is not unfrequently cut into shreds, and the transparent kind is often variously colored. Glue is in similar pieces, but usually thicker, and varies in color between pale-yellowish and dark-brown, or nearly black in the commonest varieties, and has an offensive animal odor, which is more apparent after it has been dissolved in hot water. To be adapted for dietetic or pharmaceutical purposes, gelatin should not alter in color after being digested in hot water, and the solution should be free from smell.

It is to a small extent soluble in cold glycerin, dissolves freely in hot water, forming, on cooling, a tremulous, transparent jelly, and is insoluble in alcohol and ether. Its solution in water is not precipitated by dilute solutions of alum, ferric chloride, or subacetate of lead (distinction from *chondrin*), but yields precipitates with tannin, chlorine water, corrosive sublimate, and platinic chloride. The tissues yielding gelatin likewise unite with tannin, forming leather. Gelatin dissolves in acetic and in dilute mineral acids, the solutions being known as *liquid glue*. When its solution in water is boiled for a long time it loses the property of gelatinizing on cooling. By dry distillation gelatin yields carbonate of ammonium and a number of volatile bases, which are contained in *Dippel's animal oil*. Boiled with solution of potassa, or with sulphuric acid, ammonia, *glycocol* $C_4H_9NO_2$, and *leucin* $C_6H_{13}NO_2$, are obtained among other products.

Composition.—Gelatin, also called *glutin*, consists of about 50 per cent. of carbon, 18 of nitrogen, 6.5 of hydrogen, 25 of oxygen, and 0.5 of sulphur.

Chondrin, which is obtained from the permanent cartilages by boiling with water, has a similar composition, but contains less nitrogen and more oxygen. In addition to the differences pointed out above, it is distinguished from gelatin by being precipitated by acetic and the mineral acids.

Pharmaceutical Uses.—Gelatin is employed as a reagent for *estimating tannin*, a convenient solution for the purpose being made by dissolving about 50 grams of it, together with 8 or 10 grams of alum, in a liter of distilled water; before use, the strength of the solution must be determined with a fresh solution of pure tannin. It should, however, be remembered, that the different tannins require, for complete precipitation, different amounts of gelatin, so that the results obtained are not absolutely correct. The pectic acid of oak bark, according to P. Büchner (1867), is likewise precipitated by a solution containing both gelatin and alum.

Gelatin is used for preparing the ordinary *court plaster* (see p. 516), and for the coating of pills (see *Pilulæ*). Dried in very thin layers it has been recommended, under the name of *devorative* or *folding capsules*, for the administration of powders, the thin sheets being used in precisely the same manner as paper, except that after the introduction of the powder they are permanently closed by moistening the edges, and are swallowed together with the powder, after having been softened by being dipped in water. *Medicated gelatin* is prepared by pouring a concentrated solution of gelatin, in which the medicinal substance has been dissolved, upon a polished and perfectly level surface; the sheet thus obtained is then divided into squares or disks in such a manner that each represents a definite weight of the medicine. *Gelatin capsules* are made by dipping oblong moulds of the desired size and shape into a gelatin solution; after the surface has been sufficiently coated, the capsule, while still pliant, is removed, filled with the powder or liquid, and the orifice closed by a drop of solidifying gelatin; or, for extemporaneous use, an empty capsule is slipped over the open end of another containing the medicine.

Within a few years so-called *medicinal pearls*, containing ether or other liquid, have been introduced. Hager recommends them to be made of gelatin, gum arabic, sugar, and honey, rolled out into sheets, one of which, while still rather soft, is placed upon an iron plate containing suitable cavities, into which the mass sinks; the liquid is then introduced, the orifices are closed by another sheet of the gelatin compound, the whole covered by a second iron plate having depressions exactly corresponding to those of the first, and, after screwing the plates together, their position is reversed. The pearls are finally separated by subjecting the entire arrangement to powerful pressure.

Gelatin has also been used as a base for the preparation of *medicated suppositories*, vaginal as well as rectal, and for *bougies*. The material consists of about three parts of gelatin, which, after having been soaked in water, is dissolved in seven parts of glycerin. The medicating substance should be soluble in the vehicle. Substances containing tannin are evidently not adapted for this mode of medication.

Liquid glue may be made in various ways, either by dissolving glue in acetic acid, or by adding to a strong aqueous solution of glue, nitric acid, equal to one-sixth or one-seventh of the weight of the glue. A solution of glue in spirit of nitrous ether is stated to be very serviceable, particularly if a little caoutchouc has been added to it. A solution of phosphoric acid in water, nearly neutralized by ammonium carbonate, has likewise been recommended for preparing liquid glue.

Medical Action and Uses.—Physiological experiments prove that gelatin alone cannot support animal life; but that it may become nutritious when combined with other substances, as in soup prepared from meat. In the form of calves-feet jelly it is much used during convalescence from acute disease; but its utility probably depends in great part upon the sugar, wine, and spices that season it. It has been given by enema as a lenitive in *ulceration of the rectum;* and a coating of it has been applied to *cutaneous eruptions* to protect them from the air. It is also employed in baths in chronic diseases of the skin to remove the crusts or epidermic scales, or simply to render the skin soft and pliable. For this purpose about a pound of gelatin dissolved by boiling in water is added to the bath when it is used.

GELSEMIUM, *U. S.*—YELLOW JASMINE.

Radix gelsemii.—*Yellow jessamine*, E.; *Racine de jasmin jaune*, Fr.; *Gelber Jasmin-Wurzel*, G.

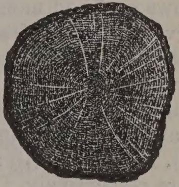
The root of Gelsemium sempervirens, *Ait.*, s. Gels. nitidum, *Mich.*, s. G. lucidum, *Poir.*, s. Bignonia sempervirens, *Lin.* Bentley and Trimen, Med. Plants, 181.

Nat. Ord.—Loganiaceæ.

Origin.—The yellow jessamine is indigenous to the Southern United States, growing in moist woods from Vrginia to Florida and Alabama, and flowering early in spring, from March to May. It has a high climbing stem, with opposite, ovate-lanceolate, entire, smooth and coriaceous leaves, and solitary or axillary clusters of very fragrant flowers, which have a bright yellow, funnel-form, five-lobed corolla, 1 to 1½ inch long, and produce a flattened two-celled fruit containing 4 to 6 winged seeds in each cell. The root and the subterraneous stem are the parts used in medicine.

Description.—The rhizome is about an inch in diameter, is externally brown-yellow, with purplish-brown longitudinal lines, and breaks with a tough fibrous fracture, showing silky bast fibres in the inner bark, a porous yellowish wood, which is traversed by whitish medullary rays and a darker colored central pith. The roots are somewhat thinner, similar in color externally, beset with numerous thin fibres, and marked by irregular longitudinal wrinkles and small scars. A transverse section shows a thin yellowish-brown bark, covering a hard pale yellowish meditullium without a central pith, but radially striate by numerous whitish medullary rays. Fragments of the thin purplish overground stem are occasionally present in the commercial article. The drug has a peculiar heavy aromatic odor, which is more marked when a larger quantity is examined. The taste of the bark is not unpleasantly bitter; that of the wood is but slight.

Fig. 82.



Gelsemium sempervirens, *Ait.*—Transverse section of root.

Constituents.—An analysis made by M. H. Kollock (1855) proved the existence of an alkaloid, *gelseminia*, besides volatile oil, starch and gummy pectinaceous and resinous principles. The existence of the alkaloid was corroborated by C. L. Eberle (1868) and Prof. Wormley (1870); the latter obtained it (1877) by acidulating a concentrated tincture with acetic acid, precipitating the resin by water, concentrating the aqueous filtrate, removing from the solution *gelseminic acid* by ether, liberating the alkaloid by carbonate of sodium, and extracting it by ether or chloroform. It is amorphous, white, intensely bitter, strongly alkaline, and slightly soluble in cold water, in which its salts dissolve quite readily. It has no very characteristic color reactions with concentrated acids; sulphuric acid produces a red color, changing to purple when heated, nitric acid a greenish, and muriatic acid a yellowish color. C. A. Robbins (1876) obtained for it the empirical formula $C_{11}H_{19}NO_2$, and observed that ceroso-ceric oxide imparts to the sulphuric acid solution a rose-cherry red color.

Robbins ascertained also the *gelseminic acid* to be identical with *æsculin*, $C_{15}H_{16}O_9$, a principle present in the bark of the horse chestnut (*Æsculus hippocastanum*, Lin.), in quassia, red saunders, etc. It crystallizes in colorless prisms, is little soluble in cold water and ether, possesses a bitterish taste, and yields with alkalies in extremely dilute solutions a characteristic fluorescence, being yellow in transmitted, and blue in reflected, light, and destroyed by acids. Æsculin is a glucoside, being split by dilute acids into glucose and *æsculetin*, $C_9H_6O_4$, which is colored yellow by alkalies, and dark green by ferric chloride.

Wormley obtained on an average 0.2 per cent. of the alkaloid, and 0.4 per cent. of æsculin. The ash of air-dry root amounts to 4 per cent. (Kollock).

Off. Prep.—Extractum gelsemii fluidum, *U. S.*

Physiological Action. *On Animals.*—Gelsemia induces paralysis both of sensation and motion, sometimes of the one first, and sometimes of the other; lowers the force and rate of the pulse and respiration, reduces the temperature, dilates the pupils, projects the eyeballs, and does not suspend the heart's action until after respiration has ceased. Death is apt to be preceded by intermittent tetanoid convulsions, which cannot be immediately reproduced like those excited by strychnia. One-eighth of a grain given subcutaneously to a strong cat caused death in an hour and a half, with symptoms of great prostration (Wormley).

On Man.—Applied topically to the eye gelsemia dilates the pupil. The characteristic symptoms of excessive and poisonous doses of gelsemium are these: Great prostration and muscular relaxation and incoördination affecting the entire system, and conspicuously paralysis of the upper eyelids and of the lower jaw (after recovery muscular debility continues for several days); the tongue is also affected; in more than one case there have been signs of spasm of the pharynx and larynx, causing extreme distress, and suggesting the phenomena of hydrophobia; the pupils are dilated; vision is double or greatly impaired; the face is congested; the mind usually clear, but in some fatal cases coma exists; the skin is warm and dry, until the approach of death, when it grows cool and moist; the general sensibility is blunted, according to some observers; the respiration is slow, irregular, and gasping, and the pulse is generally stated to be slow, small, feeble, irregular, and intermittent, but other observers declare that it is little or not at all effected. Death takes place through gradual arrest of the respiration, and usually without convulsions. In three fatal cases occurring in adults, the doses of the fluid extract were respectively, f℥j, fʒiij, and fʒij; in three similar cases observed in children the fatal doses were respectively, fʒij, fʒj, and fʒj. After death the blood remains liquid, and is dark colored; the stomach is congested, and the brain rather pale.

Medical Uses.—Gelsemium appears to be one of those too numerous remedies which have been used in a great variety of sthenic febrile diseases, upon no better ground than their power of lowering the pulse and depressing the nervous system. Incalculable mischief has been produced by them, and more is likely to be occasioned by gelsemium in febrile affections. Some of those persons who have most loudly eulogized this agent as an antipyretic, have been at great pains to explain, in opposition to the popular doctrine, that heat is death, and cold is life; that we have only to reduce the fever temperature to the normal standard or below it, to cure febrile disease, and that, therefore, gelsemium will cure fever. Unfortunately for this mode of medical reasoning, gelsemium does not reduce the temperature, except in so far as it threatens to destroy life through its poisonous operation. But such is probably not the reduction that its advocates had in view. Among a host of incongruous diseases which are said to have been "cured" by this agent, the one in regard to which very positive testimony exists, is acute or rheumatic *neuralgia*, especially of the first and second branches of the fifth nerve. For this purpose from *three to ten* minims of the fluid extract, or three times that quantity of the tincture may be given every two hours. The proper *antidote* for poisoning by gelsemium is morphia hypodermically administered.

GENISTA.—DYERS' BROOM.

Dyers' green-weed, Woad-waxen, E.; *Genêt des teinturiers*, Fr.; *Färberginster*, G.

The young branches of Genista tinctoria, *Lin.* *Nat. Ord.*—Leguminosæ, Papilionaceæ.

Description.—Dyers' broom is a low shrub, indigenous to Asia and Europe, and has been naturalized in the eastern part of the United States. The young erect branches are striately angled and have alternate sessile lanceolate entire bright-green leaves with a ciliate margin and one or one and a half inch in length. The bright yellow flowers are in elongated racemes and produce linear flat legumes, each containing from five to eight globular-obovate yellowish seeds. The recent plant, when bruised, has a rather refreshing odor and a mucilaginous, afterwards bitter and acrid taste.

Constituents.—Analyzed by Cadet de Gassicourt, the usual constituents of plants were found; but the principle giving the bitter and acrid taste was not isolated. The volatile oil is of a yellowish-green color, and the yellow coloring matter is stated to resemble that of the *weld* (*Reseda luteola*).

Medical Action and Uses.—The flowers and the seeds are both emeto-cathartic. In Russia dyers' broom was formerly vaunted as a remedy, or rather a prophylactic, for *hydrophobia.* It is hardly necessary to add that the belief in it was groundless. Much better founded was its reputation in *dropsy.* In the early part of the present century the French government published a formula for the cure of dropsy which consisted of the powdered seeds of this plant. It was given in the *dose* of a drachm in six ounces of white wine, followed in an hour by two ounces of olive oil to mitigate its operation.

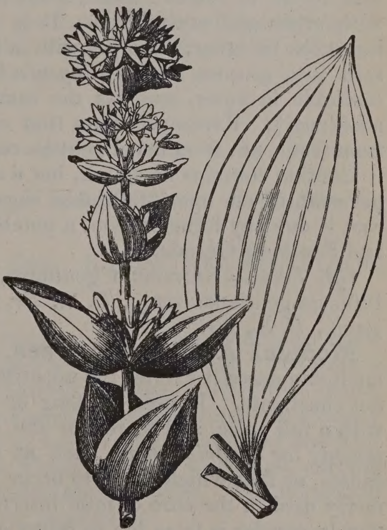
GENTIANA, *U. S.*—GENTIAN.

Gentianæ radix, Br.; *Radix gentianæ*, P. G.; *Radix gentianæ rubræ* (*vel luteæ vel majoris*).—*Gentian root*, E.; *Racine de gentiane* (*de gentiane jaune*), Fr.; *Enzianwurzel*, *Bitterwurzel*, *Rother* (*Gelber*) *Enzian*, G.

The root of Gentiana lutea, *Lin.* Steph. and Church, Med. Bot., plate 132. *Nat. Ord.*—Gentianaceæ.

Origin.—Gentian is indigenous to the mountainous regions of Southern and Central Europe, as far north as Central Germany. It has a thick hollow stem, two to four feet high, opposite, entire, five- to seven-nerved leaves, and axillary clusters of pedicellate flowers with a bright-yellow five-lobed spotted corolla, and producing a one-celled capsule containing numerous seeds.

Fig. 83.



Gentiana lutea.

Description.—The fleshy and branching one-headed to several-headed root attains a length of two to three feet and a diameter of about an inch or less, but appears in commerce always in shorter pieces, the thicker ones being longitudinally sliced before drying. Beneath the abrupt or concave, somewhat conical heads they are closely annulated, the lower portion being deeply wrinkled longitudinally, with an overlapping bark in the longitudinally split pieces. It is of a yellowish-brown color, the surface darker and grayish, the fracture short, of a slight waxy lustre, and with numerous minute brown dots. The transverse section shows a faint radiating arrangement only near the dark cambium line, and a fleshy meditullium, which is about six times thicker than the bark. The root is very hygroscopic, contains 14 to 18 per cent. of water, and is tough and flexible in moist weather. It has a faint, but heavy characteristic odor, which is more prominent in a hot infusion; its taste is sweetish, then intensely bitter, but free from astringency or acridity. Between 30,000 and 60,000 lbs. of gentian are annually imported.

The roots of other European species of Gentiana are occasionally collected with or in place of the one recognized by the Pharmacopœia; they closely resemble the latter, and have the same medicinal properties:—

Gent. purpurea, Lin., with yellowish-purple flowers, is indigenous to the Pyrenees, Alps, Apennines, Norway, and Northern Asia, and has a many-headed (8 to 10), shorter and thinner root which is darker brown internally. *G. pannonica*, Scop., with reddish or blackish purple flowers, indigenous to the mountains of Austria, has a scarcely annulated shorter, thinner, and darker root than the officinal. *G. punctata*, Lin., with straw-yellow purplish punctate flowers, is found in the Alps and eastward to the Balkan mountains; it is likewise many-headed and of a grayish-yellow brown color.

Constituents.—Kromayer (1862) was the first who isolated the pure bitter principle, which in many previous analyses had been obtained in an impure extract-like form. The crystalline *gentianin* of Henry and Caventou (1821) was in 1837 proven, by Trommsdorff and by Leconte, to be a yellow crystalline principle, subsequently named *gentisin*, *gentisic*, and *gentianic acid*, contaminated with some of the bitter matter. On washing the alcoholic extract of gentian with cold water to remove the bitter principle, afterwards with some cold ether to remove fat, and crystallizing the residue from alcohol, *gentisic acid* $C_{14}H_{10}O_5$, is obtained in bright-yellow tasteless crystals, requiring 5000 parts of water, 2000 parts of ether, and nearly 500 parts of cold alcohol for solution; it is soluble in alkalies and by ferric chloride colored deep olive-brown. J. Ville (1877) regards it as a kind of tannin and calls it *gentiotannic acid*. Hlasiwetz and Habermann (1875) obtained from it, by fusion with caustic potassa, *phloroglucin*, *acetic*, and *gentisinic acid*, the latter being $C_7H_6O_4$, and isomeric with protocatechuic acid.

Gentiopicrin $C_{20}H_{30}O_{12}$, the bitter principle of gentian, is contained in the aqueous solution of the alcoholic extract, from which it is absorbed by animal charcoal; this is boiled with alcohol, the solution concentrated, treated with lead oxide to remove color, freed from lead by sulphuretted hydrogen, agited with ether and crystallized. It is very soluble in water and ordinary alcohol, insoluble in ether, dissolves with alteration in alkalies and by dilute acids is split into glucose and *gentiogenin* $C_{14}H_{16}O_5$, which is yellowish-brown, bitter, insoluble in water, and has the same composition as *physalin* (from Physalis alkekengi). Kromayer states that crystallizable gentiopicrin is obtainable only from fresh, not from dried gentian root.

Gentian contains no starch, but a considerable amount of pectin and 12 to 15 per cent. of an uncrystallizable sugar, to which the hygroscopic nature of the root is due; by fermentation, a potable spirit is obtained from it in Switzerland and Southern Germany.

Off. Prep.—Extractum gentianæ, *U. S.*, *Br.;* Ext. gentianæ fluid., *U. S.;* Infusum gentianæ comp., *U. S.*, *Br.;* Mistura gentianæ, *Br.;* Tinct. gentianæ comp., *U. S.*, *Br.*

Medical Action and Uses.—Gentian is a pure and simple bitter. In moderate doses it excites the appetite and strengthens the digestion, and does not constipate. If used too long or too freely it is apt to occasion headache, with a full pulse, and to render the sweat and urine bitter. It is a valuable remedy for *gastric atony*, such as accompanies general debility from various causes, or that which is apt to occur in persons of a gouty habit. It was formerly used in the cure of mild intermittent fevers. The nominal *dose* of gentian in powder is from ten to thirty grains; but it is always prescribed in the form of extract, fluid extract, compound infusion, or compound tincture, all of which are officinal.

GENTIANA CATESBÆI, *U. S.*—BLUE GENTIAN.

Racine de gentiane américaine, Fr.; *Amerikanische Enzian-Wurzel*, G.

The root of Gentiana Catesbæi, *Elliott* (G. puberula, *Mich.*).

Nat. Ord.—Gentianaceæ.

Origin.—Several of the blue flowering gentians of North America are botanically very similar, and some confusion has existed concerning their identity, which is best shown by placing the species and their synonyms together, as at present recognized by Gray. We thus have—

(1) G. puberula, *Mich.;* G. saponaria var. puberula, *Gray's Man., edit. I.;* G. Catesbæi, *Ell.*, and G. Elliottii, *Chapm.*

(2) G. saponaria, *Lin.;* G. Catesbæi, *Walt.*

(3) G. Andrewsii, *Griseb.;* G. saponaria, *Frœl.;* G. fimbriata, *Vahl.*

The first species is indigenous to the States south of North Carolina, and to most States from the Alleghenies to the Mississippi; the second is met with from the mountains of North Carolina to Southern Pennsylvania, and westward to Illinois; the third species is common in the Middle States and northward. We believe that the blue gentian root, as found in commerce, is collected indiscriminately from the above three species.

Description.—The subterraneous part of these plants consists of an indistinctly annulated head about half an inch long, and one-eighth of an inch thick, which, at its base, is usually divided into a number of fleshy, nearly simple rootlets, about three inches or more in length. When dry they are of a pale, brownish color, with a distinct yellow or orange hue, and short and deep longitudinal wrinkles, devoid of fibres, quite brittle, and breaking with a short or somewhat spongy fracture, which is pale yellow. The bark is thick, and the ligneous cord quite thin. The odor and taste are gentian-like. We have found it occasionally mixed with a root of unknown origin, of similar dimensions and appearance, but having a gray hue, a tough fibrous bark, and a sweetish, scarcely bitter taste.

Constituents.—From experiments made with the root we conclude that its constituents are probably identical with those of *G. lutea.*

Medical Action and Uses.—Blue gentian is employed to some extent in popular practice, in the southern portion of the United States, for the same diseases and in the same manner as European gentian.

GERANIUM, *U. S.*—GERANIUM.

Cranesbill root, E.; *Racine de bec-de-grue tacheté, Racine de pied-de-corneille*, Fr.; *Fleckstorchschnabel-Wurzel*, G.

The rhizome of Geranium maculatum, *Lin.* Bigelow, Med. Bot. I. t. 8; Bentley and Trimen, Med. Plants, 42.

Nat. Ord.—Geraniaceæ.

Origin.—This perennial herb is very common in rich woods in most parts of Canada and the United States, and it flowers from April to July. The stem is from one to two feet high; the hairy leaves, when old, become blotched with white, and are palmately 5- or 7-lobed, with wedge-shaped divisions, which are coarsely toothed above; the light purple flowers are in loose terminal umbels; the fruit is long-beaked, with five one-seeded carpels, which separate when ripe, curving upward together with the style which separates from the beak. The horizontal rhizome should be collected late in summer or in autumn.

Description.—It is two to three inches long, a quarter to half an inch in diameter when fresh, little branched, but tuberculated with the remnants of the stems, longitudinally wrinkled, with indistinct nodes, dark-brown externally, red-brown internally. It breaks with a nearly smooth fracture, showing a thin bark, and the small, yellowish, broadly wedge-shaped wood bundles arranged in a circle near the cambium, and inclosing a large central pith. It has no odor; its taste is purely astringent. The rootlets are mostly on the lower side, are much shrunken, fragile, and branched into hairlike fibres.

Constituents.—The analyses of Staples (1829), and Bigelow (1833), indicate, besides tannin, the presence of starch, pectin, sugar, mucilage, etc.

Bowman (1869) found 13 to 17 per cent. of tannin, which has not been further investigated.

Allied Plants.—Geranium Robertianum, *Lin.*, *Herb Robert*, grows in shady thickets and woods in Europe, in the United States and Canada; has an erect branching stem, deeply 3- or 5-divided leaves, with the divisions twice pinnatifid, and the lobes ovate and mucronately toothed, and rose- or purplish-colored flowers. It has a strong, rather unpleasant odor, and a bitterish, saline, and astringent taste.

Erodium cicutarium, *L'Her.* (Geranium, *Lin.*), Storksbill, indigenous to the Levant and Southern Europe, is sparingly naturalized in the United States. It has a low spreading stem, pinnate leaves, with the leaflets sessile and pinnatifid, and pale-reddish flowers. The odor of the bruised plant resembles that of carrot.

Erodium moschatum, *Ait.*, is found near the Mediterranean and in Southern Africa, and resembles the preceding, but has a rather strong, musk-like odor.

Off. Prep.—Extractum geranii fluidum, *U. S.*

Medical Action and Uses.—Cranesbill is a pure astringent, and may be profitably used in the treatment of subacute and chronic *diarrhœa.* A decoction of it in milk is employed in *cholera infantum.* A decoction, made by boiling an ounce of the root in a pint and a half of water to a pint, is sometimes used in *aphthæ* of the mouth and fauces, in relaxed conditions of the *throat*, *vagina*, and *rectum*, to restrain internal *hemorrhages*, and to cure *leucorrhœa*, *gleet*, etc. The *dose* may be stated at from twenty to forty grains of the powdered rhizome; or from one to two fluidounces of the decoction. The fluid extract is officinal.

GEUM, *U. S.*—WATER AVENS.

Radix caryophyllatæ aquaticæ, Radix benedictæ sylvestris.—Racine de benoite aquatique (de benoite des ruisseaux), Fr.; *Sumpfnelkenwurzel, Wasser-Benedikten-Wurzel*, G.

The rhizome with the rootlets of Geum rivale, *Lin.*

Nat. Ord.—Rosaceæ, Dryadeæ.

Origin.—This perennial plant grows in wet meadows and moist woods in hilly localities of North America, from Pennsylvania northward, and is likewise indigenous to Central and Northern Europe and Northern Asia. It has a stem 1 to 2 feet high, with lyrate or interruptedly pinnate root-leaves, and trifoliate or 3-lobed stem-leaves, the leaflets or lobes being obovate or cuneate oblong; the bell-shaped calyx is purplish-brown, the 5 petals are clawed, purplish-yellow, and veined.

Description.—The rhizome is nearly horizontal, 2 to 3 inches long, about $\frac{1}{4}$ inch thick, somewhat branched, tuberculate above from the bases of the stems, and there densely beset with red-brown hairy leaf-sheaths. It is externally blackish-brown, breaks with a rather short and waxy fracture, has a thin purplish-brown bark, brown-gray pith, and small distant light-colored wood-wedges. It has a very faint, somewhat clove-like odor, and a bitterish astringent taste.

Water avens has not been analyzed; its constituents are probably similar to those of the yellow-flowered *Geum urbanum*, Lin., or *avens*, which grows in Europe in woods and shady places, and has an oblique or perpendicular rhizome 1 or 2 inches in length, abrupt below or passing into the main or tap-root; it is hard, dark brown, tuberculate, and beset with dark-brown membranous scales; the numerous thin fibres are pale brown and 3 to 4 inches long; the wood is in 5 or 6 broad and rounded wedges, and incloses a large purplish pith. It has a distinct clove-like odor, and a bitter astringent taste. It is known in Europe as *radix caryophyllatæ.*

Constituents.—Avens, according to Buchner (1844), contains a small quantity of a volatile oil, possessing acid properties, about 3 per cent. of tannin, and a bitter principle which appears likewise to possess acid properties. The remaining constituents, sugar, fat, resin, etc., are not of medicinal importance.

Medical Action and Uses.—Water avens is very like in its action to avens, G. urbanum. Both are very astringent, and more or less tonic. Like other agents with these qualities it is apt to derange the digestion and cause vomiting if too freely given. It has been employed in all forms of disease of the mucous membranes depending upon relaxation and attended with excessive and altered secretions, including atonic *dyspepsia*, *diarrhœa*, *bronchorrhœa*, *leucorrhœa*, etc. It has also been used in chronic *rheumatism*, *scrofula*, slight *intermittent fevers*, and in *menstrual derangements* depending on debility. The *dose* is represented by about thirty grains of the powdered root; but it is best administered in a decoction made by boiling an ounce of the root in a pint of water, which may be given in *doses* of one or two fluidounces.

GILLENIA, *U. S.*—GILLENIA.

Indian physic, *Indian hippo*, *American ipecac*, *Bowman's root*, E.; *Racine de gillénie*, Fr.; *Gillenienwurzel*, G.

The rhizome with the rootlets of Gillenia trifoliata, *Moench* (Spiræa trifoliata, *Lin.*), and of Gillenia stipulacea, *Nutt.* (Spir. stipulata, *Willd.*).

Nat. Ord.—Rosaceæ, Spiræeæ.

Origin.—Both species are perennial herbs indigenous to the United States, the first being found almost exclusively east of the Alleghenies from New York south to Georgia, the other is found from New York westward and southward to Alabama. The plants are 2 to 3 feet high, branched, with nearly sessile trifoliate doubly serrate or incised leaves, and loose corymbs of pale rose-colored or white flowers, the calyx of which is tubular and constricted at the throat, the 5 unequal petals being long linear-lanceolate. The two plants are readily distinguished by their stipules, which, in *G. trifoliata*, are awl-shaped and entire, and in the larger *G. stipulacea* are large, leaf-like, ovate, and incised. The officinal portion is the rhizome and rootlets.

Description.—The rhizome of *G. stipulacea*, which is usually found in commerce, is nearly horizontal, about 1 inch thick, very knotty from the numerous branches and remnants of stems. The larger rootlets are $\frac{3}{8}$ inch thick near the base, tortuous, irregularly branched; the smaller rootlets are undulated, and have a knotty or annulated appearance from the semicircular constrictions of the bark on one side, and the depressions on the opposite side. The rhizome and rootlets of *G. trifoliata* are smaller and less knotty, the rootlets often smooth or indistinctly annulated. Both have a reddish- or grayish-brown color externally, and are hard and very woody, breaking with some difficulty except through the brittle bark. The bark of the rhizome is thin, the wood about 8 times thicker, of a whitish color, with several annual rings inclosing a thin pith, and traversed by fine medullary rays. The bark of the root is of uneven thickness, in its outer layer brownish-red, the inner layer reddish-white, with numerous minute red resinous dots. The odor is very slight; the taste of the bark is bitter, not unpleasant, exciting the flow of saliva; the wood is tasteless.

Constituents.—The various analyses made of gillenia have established the presence of starch, tannin, gum, albumen, fat, and resin, etc. The bitter principle, *gillenin*, not quite pure yet, has been obtained by W. B. Stanhope (1856) in the form of a whitish powder, having a slight odor and a very bitter taste, neutral to test-paper, soluble in water, alcohol, ether, and dilute acids, and colored blood-red by nitric acid. Its watery solution is stated to be precipitated by subacetate of lead, tartar emetic, and potassa, but not by tannin; ½ grain caused much nausea. It was prepared by washing the alcoholic extract with water, treating the residue with very dilute sulphuric acid, adding magnesia, evaporating, and exhausting the dry mass with alcohol.

Medical Action and Uses.—The popular title of American ipecacuanha sufficiently indicates the prominent virtue of this medicine. It is a mild emetic. The *dose* is twenty or thirty grains. The allied species, G. stipulacea, has identical qualities. Gillenin, when pure, will produce nausea and vomiting in *doses* of from one-half to one grain. Injected into the femoral vein of a dog it excited vomiting.

GLECHOMA.—GROUND IVY.

Herba hederæ terrestris.—Lierre terrestre, Fr.; *Gundermann, Gundelrebe*, G.

Glechoma hederacea, *Lin.*, s. Nepeta glechoma, *Benth.*

Nat. Ord.—Labiatæ, Nepeteæ.

Description.—Ground ivy is a creeping and trailing perennial, which is common in Europe and naturalized in various parts of North America. The ascending branches are from 6 to 10 inches long, quadrangular, and have opposite petiolate leaves, which are 1 or 1½ inch long, round-reniform, deeply crenate, green, and underneath often purplish. The blue or purplish flowers are in small axillary clusters, from 2 to 5 in number. The plant has a slight balsamic odor, and a bitter, somewhat acrid, taste.

Constituents.—These are doubtless similar to those of other plants of the same natural order, and comprise volatile oil, resin, etc.

Medical Action and Uses.—Ground ivy is said to act poisonously upon horses and sheep. It has been chiefly used in medicine in the treatment of *chronic bronchitis*, and its virtues in this affection are attested by medical evidence as well as by popular faith. It was at one time reputed to be a cure for consumption, by which was meant not that incurable disease which depends upon tuberculosis, but chronic bronchitis with muco-purulent sputa. It had also some reputation in catarrhal affections of the *urinary* organs, and in atonic *dyspepsia*. Externally the herb has been applied in poultices, or merely in a contused state to indolent ulcers. An infusion may be made with an ounce of the herb to a pint of boiling water, and given in wineglassful doses.

GLYCERINA, *U. S.*—GLYCERIN.

Glycerinum, Br., P. G.—*Glycerine*, E.; *Glycérine*, Fr.; *Glycerin, Oelsüss*, G.

Formula $C_3H_8O_3$. Molecular weight 92.

A sweet principle obtained from fat and fixed oils.

Origin.—Glycerin, which is not found in the free state, except in some rancid fats, exists in combination with the so-called fatty acids, forming compound ethers, which constitute most of the animal and vegetable, solid and liquid, fats. It is formed in small quantities during the fermentation of saccharine liquids. Scheele, who discovered it, in 1779, called it *sweet principle of oils*.

Preparation.—To obtain glycerin, fat must be decomposed into its proximate constituents, either by a caustic alkali, as in the manufacture of soap, or by oxide of lead, as in the preparation of lead plaster, or by the action of water at an elevated temperature under high pressure. The latter process, which was patented in 1854 by R. A. Tilghman, yields the acids of the fat and an aqueous solution of glycerin. Water which has been agitated with recently prepared lead plaster is likewise such a solution, and the liquor from which soap has been separated contains glycerin, saline matters, and various organic impurities, which may be removed by treatment with the necessary precipitants and with charcoal, the solutions being finally evaporated and distilled with steam under pressure.

Properties.—Glycerin is a syrupy liquid having the specific gravity 1.28 at 15° C. (59° F.) (Pelouze); the officinal glycerin has a density of 1.25. It is colorless, inodorous, very sweet, without action upon litmus, and soluble in all proportions in water and alcohol, but not in ether. In contact with the air, glycerin distils only partially unchanged, the greater portion being destroyed with the production of very acrid *acrolein* among the empyreumatic liquids. Its boiling point is 290° C. (554° F.). At a red heat it takes fire and burns without leaving any residue. It dissolves all deliquescent salts, is a solvent for many organic and inorganic compounds which are soluble in water or alcohol, and prevents the precipitation of some salts by alkalies and other reagents. Under certain circumstances, for which continued agitation and a very low temperature appear to be essential, glycerin will congeal into a solid crystalline mass.

Chemically, glycerin is a triatomic alcohol, and forms with acids three series of ethers in which 1, 2, or 3 atoms of hydrogen are replaced by the corresponding number of univalent acidulous radicals. The so-called neutral fats are saturated ethers, like *tripalmitin*, $C_3H_5O_3.3C_{16}H_{31}O$. A similar compound is *nitroglycerin* or *glonoin*, $C_3H_5O_3.3NO_2$, which is obtained on adding glycerin by drops to a mixture of concentrated nitric and sulphuric acids immersed in a freezing mixture, and afterwards pouring into water. Nitroglycerin is a heavy colorless oily liquid, which is insoluble in water, very poisonous, and violently explosive. It forms the basis of *dynamite* and similar explosive mixtures.

When heated with an excess of phosphoric anhydrid, $2H_2O$ are abstracted, and the glycerin is converted into *acrolein*, C_3H_4O, which is a light, very refractive, and volatile oily liquid, the vapors of which are extremely irritating to the eyes.

Glycerin dissolved in water and kept, with yeast, at a temperature of about 25° C. (77° F.) is converted into *propionic acid;* and with chalk and old cheese at 40° C. (104° F.) it yields *alcohol* and *butyric acid.* When slightly diluted with water, and heated to just above 100° C. (212° F.) in the presence of oxalic acid, the latter will be decomposed into *carbonic* and *formic acids.* $C_2H_2O_4$ yields $CO_2+CH_2O_2$; the formic acid may be afterwards obtained by *repeatedly* diluting with water and distilling. Glycerin unites with the alkalies and alkaline earths to compounds soluble in water, the former also in alcohol; the latter are not precipitated by carbonic acid. It unites also with sulphuric and other acids.

Impurities and Adulterations.—Glycerin is now rarely adulterated, but much being prepared for uses in the arts, where purity is not necessary, impure glycerin may at all times be met with in the market. Water, mucilage, glucose, and perhaps cane-sugar syrup would be used as adulterants. The first is detected by the specific gravity of the sample; the others by the brown color produced on mixing the sample with twice its bulk of concentrated sulphuric acid. Since cane-sugar syrup which has been exposed to the light for some time contains appreciable quantities of glucose, glycerin adulterated with either kind of sugar will yield a red precipitate when heated to boiling with a drop of solution of copper sulphate and an excess of potassa.

The impurities may consist of saline matters should the glycerin have not been distilled, or of odorous compounds if insufficiently purified by distillation. The odor becomes apparent on warming the glycerin or rubbing it well upon the hand. Most of these compounds reduce nitrate of silver and produce a more or less deep color when glycerin is diluted with a little distilled water, and after the addition of a few drops of nitrate of silver heated to boiling. The same reagent will detect chlorides by the white precipitate produced. Diluted glycerin should not be colored or rendered turbid on being tested with sulphuretted hydrogen or sulphydrate of ammonium (metallic salts), ammonium oxalate (calcium), or barium chloride (sulphuric or oxalic acid). The presence of butyric acid is readily determined by warming a mixture of glycerin with one-fourth its measure each of alcohol and sulphuric acid, when butyric ether, recognized by its odor of pineapples, will be given off. The most important tests for practical purposes are those with sulphuric acid and nitrate of silver. Goddefroy (1874) has recommended the heating of glycerin in an open crucible to boiling, and then igniting it, when it should burn without diffusing the least smell or leaving the least residue.

Pharmaceutical Uses.—Glycerin forms the base of the officinal *glycerita* (*glycerina*), and is a constituent of a number of officinal fluid extracts; also of Linimentum potassii iodidi cum sapone, *Br.* It is used for preserving pill masses in a plastic condition, and for preventing fermentation and other changes in aqueous liquids containing organic matter in solution.

Medical Action and Uses.—The purest glycerin is irritating on account of the avidity with which it abstracts moisture from the tissues; but commercial glycerin has sometimes a similar defect from containing nitric, sulphuric, or organic acids, and other impurities. It is alleged that glycerin mixed with the food of animals tends to fatten them while it diminishes the proportion of urea excreted. If given in larger doses than can be digested, it may be detected in the urine, but it cannot be recognized in the feces or the sweat. In excessive doses (such as f℥ss for every two pounds and a half of the animal's weight) its effects resemble those of alcoholic poisoning, including the gastric lesions found after death. Injected hypodermically the same symptoms and lesions are produced.

Its richness in carbon suggested its use as medicinal food, and especially as a substitute for cod-liver oil; but, as in so many other instances, a little clinical experience showed the so-called scientific inductions to be untrue. On theoretical grounds, also, it has been used in the treatment of *diabetes*, but without striking advantage, although when the amount of sugar excreted is very small the use of glycerine may cause it to disappear from the urine, at least in its usual form. It has been thought to retard emaciation in this disease. Its medicinal virtues depend almost entirely upon its having no tendency to evaporate, and to its undergoing no change by exposure to the air. Hence it may be advantageously used in all cases in which oil has, from time immemorial, been employed; and, owing to its solubility in water, with more effect. Thus it has been applied, with good results, to the rectum in *dysentery*, to the larynx, trachea, and bronchia (by atomization and inhalation), in various diseases of the *air passages* exciting cough and spasm, or causing their obstruction. Mixed with water or pure, according to circumstances, it forms the best solvent for hardened *cerumen* and epithelial scales, and the best agent for keeping the *tympanum* moist. It has been much used in the treatment of recent *wounds*, but with far less satisfactory results than are obtained by dry dressings that exclude the air. When these cannot be employed, glycerin may be profitably substituted. Its affinity for moisture tends, in certain cases, to limit the secretion of pus by drying and constringing the secreting surface. This is strikingly the case in *leucorrhœa*. The addition of an astringent, tannic acid, for example, increases the efficacy of the glycerin, which should be applied upon a tampon of lint. A similar application may be used for *fissure of the anus*, and for fissured *nipples*. For the latter, however, a mixture of compound tincture of benzoin and glycerin is preferable. *Fissured tongue* is curable by a solution of forty grains of borax in about an ounce of glycerin and four ounces of water. Pure glycerin applied to *carbuncles*, *boils*, and *abscesses* is said to promote their cure; but it is unsuited for application over a large surface, owing to its affinity for the moisture of the air. It allays *itching* in most affections attended with this symptom, and hence is an appropriate ingredient of ointments and washes used in their treatment. To prevent the *laryngeal mirror* from becoming obscured by the condensation of vapor upon its surface, it has been recommended to pass lightly over it a cloth wet with glycerin. *Dryness of the mouth* from fever or any other cause may be lessened by a mixture of glycerin and water far better than by water alone.

The solvent powers of glycerin have suggested the glycerites as officinal forms of certain medicines, but many others are prescribed extemporaneously. A solution of iodide of potassium in two parts of glycerin, with the addition of one part of iodine, makes an almost caustic preparation. A solution of one part of iodine in five parts of glycerin is used as a resolvent of enlarged and indurated glands, as a revulsive over inflamed joints, abscesses, etc. One part of glycerin and eight parts of sulphate of zinc form an energetic caustic. Vaccine lymph may be preserved from decomposition by mixing it with glycerin.

GLYCERITA, *U. S.*—GLYCERITES.

Glycerina, Br.; *Glycerata*, *Glycerolata.*—*Glycerins*, *Glycerols*, E.; *Glycérés*, *Glycerats*, *Glycérolés*, Fr.; *Glycerite*, *Glycerolate*, G.

This class of preparations consists mostly of solutions in undiluted glycerin, which are readily made by trituration in the mortar. Two of the officinal glycerites require different manipulations which will be noticed in the proper place. These preparations were suggested in 1854 by Cap and Garot, and soon after became favorably known and have become much used.

GLYCERITUM ACIDI CARBOLICI, *U. S.*—GLYCERITE OF CARBOLIC ACID.

Glycerinum acidi carbolici, Br.; *Glycerine of carbolic acid*, E.—*Glycérolé d'acide phénique*, *Glycérine phéniquée*, Fr.; *Phenol- (Phenyl-) Glycerit*, G.

Preparation.—Take of Carbolic Acid two troyounces; Glycerin half a pint. Rub them together in a mortar until the acid is dissolved. *U. S.*

Take of Carbolic Acid one ounce; Glycerin four fluidounces. Rub them together in a mortar until the acid is dissolved. *Br.*

Off. Prep.—Aqua acidi carbolici, *U. S.*

Medical Uses.—This is a convenient form for the application of carbolic acid in certain *eruptions of the skin*, such as scabies, prurigo, etc., in which the itching is tormenting.

GLYCERITUM ACIDI GALLICI, *U. S.*—GLYCERITE OF GALLIC ACID.

Glycerinum acidi gallici, Br.—*Glycerine of gallic acid*, E.; *Glycérolé d'acide gallique*, Fr.; *Gallussäure-Glycerit*, G.

Preparation.—Take of Gallic Acid two troyounces; Glycerin half a pint. Rub them together in a mortar; then transfer to a glass or porcelain capsule, and heat gently until the acid is dissolved. *U. S.*

Take of Gallic Acid one ounce; Glycerin four fluidounces. Rub them together in a mortar; then transfer the mixture to a porcelain dish, and apply a gentle heat until complete solution is effected. *Br.*

Medical Uses.—This preparation taken internally has the advantage over gallic acid in substance of being more readily absorbable. The *dose* is from twenty to sixty minims.

GLYCERITUM ACIDI TANNICI, *U. S.*—GLYCERITE OF TANNIC ACID.

Glycerinum acidi tannici, Br.—*Glycerine of tannic acid* (*of tannin*), E.; *Glycérolé de tannin*, *Glycerine tannique*, Fr.; *Tannin-Glycerol*, G.

Preparation.—Take of Tannic Acid two troyounces; Glycerin half a pint. Rub them together in a mortar; then transfer to a glass or porcelain capsule, and heat gently until the acid is dissolved. *U. S.*

Take of Tannic Acid one ounce; Glycerin four fluidounces. Rub them together in a mortar; then transfer the mixture to a porcelain dish, and apply a gentle heat until complete solution is effected. *Br.*

Medical Uses.—This glycerite is not so often used internally as that of gallic acid; but as a local application to *suppurating surfaces* of limited extent it is more efficient, *e. g.*, to the nostrils in chronic *coryza* and *ozæna*, to the *ear* in chronic catarrh, to the *throat* in chronic relaxation of its mucous membrane, etc. It is a useful dressing for certain chronic but irritable cutaneous eruptions, *e. g.*, *eczema*, *impetigo*, *intertrigo*, etc.

GLYCERITUM AMYLI.—GLYCERITE OF STARCH.

Glycerinum amyli, Br.—*Glycerine of starch*, *Glycamyl*, *Plasma*, E.; *Glycéré d'amidon*, *Glycérat simple* (*d'amidon*), Fr.; *Stärke-Glycerit*, G.

Preparation.—Take of Starch one ounce; Glycerin eight fluidounces. Rub them together until they are intimately mixed, then transfer the mixture to a porcelain dish, and apply a heat gradually raised to 240° F., stirring it constantly until the starch particles are completely broken and a translucent jelly is formed. *Br.*

This preparation was introduced into British pharmacy by G. F. Schacht in 1858, and soon after became known in the United States. To obtain a uniform jelly-like mass, the starch should be first rubbed into a fine powder, free from lumps, and then heated with the glycerin until all starch granules are ruptured, and the liquid is thickened to a translucent mass free from white spots.

For the same purpose T. B. Groves (1867) introduced a preparation under the name of *glycelæum*, which, besides glycerin, contains fixed oil; it is made by triturating half an ounce of fine almond meal with one ounce of glycerin, and then incorporating with it three ounces of olive oil, gradually added. The oil may wholly or in part be replaced by volatile oil or oleoresins. The preparation is a soft semi-gelatinous paste, which admits of the further addition of powders, and when mixed gradually with water, forms readily an emulsion.

Medical Uses.—This preparation forms a transparent, unchangeable, and unirritating compound. It has been much used in ophthalmic surgery, especially when medicinal agents were to be applied to the *conjunctiva*. Ordinary ointments are still to be preferred in affections of the eyelids. It answers the purpose of a light poultice in erythema, erysipelas, furuncle, intertrigo, and various other local inflammations of the skin.

GLYCERITUM PICIS LIQUIDÆ, *U. S.*—GLYCERITE OF TAR.

Glycerol of tar, E.; *Glycérolé de goudron*, Fr.; *Theerglycerol*, G.

Preparation.—Take of Tar a troyounce; Carbonate of Magnesium in powder two troyounces; Glycerin four fluidounces; Alcohol two fluidounces;

Water ten fluidounces. Having mixed the glycerin, alcohol, and water, rub the tar in a mortar, first with the carbonate of magnesium, and then with six fluidounces of the mixed liquids gradually added, and strain with expression. Rub the residue in like manner with half the remaining liquid, and strain as before. Repeat the process again with the remaining liquid. Put the residue into a percolator, add gradually the expressed liquids previously mixed, and afterwards a sufficient quantity of water to make the liquid, which passes, measure a pint. *U. S.*

This is essentially the formula proposed by J. B. Moore in 1869. The glycerite is of a rich reddish-brown color, and perfectly transparent when recently prepared, but gradually deposits blackish resinous matter, which should be filtered off.

Medical Uses.—Glycerite of tar is a convenient substitute for tar ointment in pruriginous and squamous affections of the skin.

GLYCERITUM SODII BORATIS, *U. S.*—GLYCERITE OF BORAX.

Glycerinum boracis, Br.—*Glycerine of borax*, E.; *Glycérolé de borax*, Fr.; *Borax-Glycerol*, G.

Preparation.—Take of Borate of Sodium two troyounces; Glycerin half a pint. Rub them together in a mortar, until the borate of sodium is dissolved. *U. S.*

Take of Borax in powder one ounce; glycerin four fluidounces. Rub them together in a mortar until the borax is dissolved. *Br.*

Medical Uses.—In this preparation the glycerin forms a convenient substitute for the honey usually employed along with borax in *aphthous* and other ulcerative affections of the *mouth*, *nipples*, *vulva*, etc., but is probably less efficient. It is more suitable for *pityriasis* of the scalp.

GLYCYRRHIZA, *U. S.*—LIQUORICE ROOT.

Glycyrrhizæ radix, Br.; *Radix liquiritiæ glabræ*, P. G.; *Radix glycyrrhizæ hispanicæ.*—*Licorice root, Spanish liquorice root*, E.; *Réglisse, Bois de réglisse, Bois doux, Racine douce*, Fr.; *Spanisches Süssholz, Spanische Süssholzwurzel*, G.

The root (and underground stem) of Glycyrrhiza glabra, *Lin.*, s. Liquiritia officinalis, *Mœnch.* Woodv., Med. Bot., t. 152; Bentley and Trimen, Med. Plants, 74.

Nat. Ord.—Leguminosæ, Papilionaceæ.

Origin.—This perennial is indigenous to the countries on the northern shore of the Mediterranean and further east to the Caucasus and Northern Persia. A well-marked variety, Gl. glandulifera, *W. and K.*, with the leaves glandular hairy beneath, and the legumes glandular prickly, grows from Hungary eastward through Southeastern Europe and further on into Persia. The typical form is cultivated in England, France, and Germany, and also to a limited extent in the United States. The stout roots penetrate deeply into the ground, while long horizontal rhizomes or runners are produced near the surface. The herbaceous overground stems are about 4 feet high, and have impari-pinnate leaves with oval-oblong mucronate leaflets, which are glutinous beneath, and racemes of white and purplish flowers producing brown legumes containing about 4 seeds. The roots and rhizomes are collected together and assorted before being brought into commerce. About 11,000,000 pounds of liquorice root are annually imported into the United States.

Description.—Liquorice root consists of long cylindrical pieces varying in thickness from ¼ to 1 inch, which are longitudinally wrinkled, covered with a grayish-brown warty cork, and break with a fibrous fracture. Transverse section shows a bark, about one-sixth the diameter of the root in thickness, underneath the cork of the grayish-yellow color of the wood and in its inner layer radiately striate from the long, narrow, and somewhat wavy bast wedges. The woody meditullium consists of tough fibro-vascular tissue, appearing porous from the large vessels, and forming narrow wedges separated from one another by still narrower medullary rays. The rhizome has the same appearance and structure, and, in addition, a thin central pith. Liquorice root has a peculiar odor and a strongly sweet somewhat acrid taste.

RADIX LIQUIRITIÆ MUNDATA S. RUSSICA, RADIX GLYCYRRHIZÆ ECHINATÆ, Russian liquorice root, is generally stated to be obtained from Glycyrrhiza echinata, *Lin.*, which is indigenous to Italy, Southern Russia, and further east to Central Asia. Flückiger and Hanbury presume it to be derived from *Glyc. glabra* var. *glandulifera.* It consists chiefly of the main root, and is about a foot long and 1 to 3 inches thick, often hollow above, usually deprived of the brownish corky layer, and furnished with a light, grayish-yellow, thin bark, covering a more porous wood which is often fissured in the direction of the medullary rays. It has a very sweet taste, and yields a lighter-colored powder than the former kind.

Constituents.—Robiquet (1809) obtained from liquorice root *starch*, *asparagin*, *albumen*, a *resinous oily matter*, to which the slight acrid taste of the root is due, and *glycyrrhizin.* Roussin (1875) found the latter to be present in the root, in combination with ammonia, as *glycyrrhizate of ammonium*, which he obtained pure from the cold infusion by precipitating with sulphuric acid, washing the precipitate well with water, dissolving it in strong alcohol, and adding ether, whereby a blackish mass is precipitated; the clear liquid is then carefully mixed with small quantities of alcoholic solution of ammonia. The precipitate is yellowish, very light, and by evaporating its aqueous solution is obtained in brittle, translucent, shining scales. *Glycyrrhizin*, prepared by the same process, with the exception of the final treatment with ammonia, was found by Gorup-Besanez (1861) to have the composition $C_{24}H_{36}O_9$, to be soluble in alcohol, ether, and hot water, and on boiling with dilute acids, to be split into glucose and a bitter resinous substance named *glycyrretin*, which is insoluble in water, but dissolves in alcohol and alkalies. By fusing it with potassa, Weselski and Benedikt (1876) obtained *paraoxybenzoic acid*, $C_7H_6O_3$.

Allied Drugs.—ABRUS PRÆCATORIUS, *Lin.*, or *Indian liquorice* (Bentley and Trimen, Med. Plants, 77), is a small twining shrub, growing wild and much cultivated in tropical countries, where the bright scarlet seeds, which are marked with a black spot at the hilum, are employed like beads. The long woody root is about ½ inch or less in diameter, externally pale reddish-brown, internally yellowish; it has a thin bark, a peculiar disagreeable odor, and a bitterish acrid flavor, leaving a faintly sweet after-taste (Pharmacographia). In India, it is used in place of liquorice root. Berzelius (1827) found the leaves to contain a sweet principle similar to that of liquorice.

Off. Prep.—Confectio terebinthinæ, *Br.*; Decoct. sarsaparillæ (sarsæ) comp., *U. S.*, *Br.*; Extract. glycyrrhizæ, *Br.*; Extract. glycyrrh. fluid., Extract. sarsaparillæ fluid. comp., *U. S.*; Infusum lini (lini comp.), *U. S.*, *Br.*; Pilula ferri iodidi, *Br.*; Pil. hydrargyri, *U. S.*, *Br.*; Pulv. glycyrrhizæ comp., *Br.*; Syrup. sarsaparillæ comp., *U. S.*

Medical Action and Uses.—Liquorice root is demulcent, laxative, and locally is slightly stimulant; it is supposed to promote the secretions of the congested mucous membrane of the air-passages. The infusion is a useful drink in *febrile catarrhal affections*, especially those attended with much thirst, and in febrile and irritative disorders of the *bowels* and *urinary organs.* In these cases, it is usually prepared with flaxseed, rice, barley, or gum-water. It is said that an infusion of liquorice root may be used by diabetic patients without aggravating the disease. Liquorice root is a constituent of a very excellent laxative prepared as follows: ℞. Senna, liquorice root, of each, ℥ij; Fennel seed, sulphur, of each, ℥j; Refined sugar, ℥vj. Mix, and reduce by trituration to an impalpable powder. *Dose*, a small teaspoonful in half a tumbler of water, at bedtime. Liquorice root is also used to correct the acrid or bitter flavor of certain medicines, such as quinia, colocynth, aloes, quassia, seneka, mezereon, guaiacum, and sal-ammoniac; but for this purpose the extracts and the syrup are more convenient.

GNAPHALIUM.—Life-everlasting.

Pied de chat, Immortelle, Fr.; *Katzenpfötchen, Immerschön*, G.

The flowers and flowering herb of different species of Gnaphalium and allied genera.

Nat. Ord.—Compositæ, Senecionideæ.

Description.—Gnaphalium polycephalum, *Lin.*, grows in fields and woods of North America. It is a woolly annual, with lanceolate nearly entire leaves, and with the numerous ovate and obovate flower-heads in dense corymbose clusters terminating the branches; the involucral scales are dry, scarious, and whitish, the tubular florets yellowish. The plant is quite fragrant, and has a bitterish and aromatic taste.

Gnaph. margaritaceum, *Lin.*, s. Antennaria margaritacea, *R. Br.*, grows in similar localities with the preceding, chiefly northward, and has larger roundish-ovate heads, which are of a pearly whiteness and slight odor.

Gnaph. (Helichrysum, *D. C.*), arenarium, *Lin.*, grows in Europe and Asia. The heads are globular-oblong, $\frac{1}{6}$ inch long, of a lemon- or orange-yellow color and agreeable odor.

Gnaph. dioicum, *Lin.*, s. Antennaria dioica, *Gaertn.*, is indigenous to Europe. The barren flower-heads are hemispherical and whitish, the fertile ones more top-shaped and reddish or purplish. The species is very closely related to Antennaria plantaginifolia, *Hook.*, which is common in North America.

Constituents.—These plants appear to contain a little volatile oil and bitter principle.

Medical Action and Uses.—In Europe, the leaves and flowers of several species, which have, when chewed, an agreeable aromatic and slightly bitter and astringent taste, are used in infusion in chronic *bronchitis* and *diarrhœa*, and in poultices to unhealthy *ulcers*. All the species are employed under similar circumstances. They may be given in an infusion made with half an ounce of the plant to a pint of water.

GOSSYPII RADICIS CORTEX, *U. S.*—Bark of Cottonroot.

Cottonroot bark, E.; *Écorce de racine de cottonnier*, Fr.; *Baumwollen-Wurzelrinde*, G.

The bark of the root of Gossypium herbaceum and of other species of Gossypium.

Nat. Ord.—Malvaceæ.

Origin.—The different species of Gossypium are indigenous to the tropical and subtropical countries of Asia and Africa, and have been cultivated from a very early period, whereby many characteristic varieties have been produced. They are herbaceous or shrubby plants or small trees, with three to five-lobed leaves and showy axillary flowers, having a three-leaved involucre, a cup-shaped calyx, five petals, numerous stamens, and producing a three to five-celled capsule, which opens by as many valves; the numerous seeds are densely covered with long woolly hairs. According to A. W. Chapman, the long staple or Sea Island cotton cultivated in the United States is referred to *Goss. nigrum*, Haworth, and the short staple or upland cotton to *Goss. album*, Haw. The seeds of *Goss. religiosum*, Lin., are invested with a yellow wool. Cottonroot is conical, nearly simple or little branched, hard and woody, and covered with a thin bark which is officinal.

Description.—Cottonroot bark is in bands or quilled pieces, one-half line thick, covered with a brownish-yellow, satiny, very thin cork, by the abrasion of which irregular dull brownish-orange patches appear. The cork forms slight longitudinal ridges, which are often confluent into elongated meshes and marked with black circular dots or short transverse lines. The inner surface is whitish or reddish-white, of a nearly silky lustre, and finely striate in a longitudinal direction by the thin medullary rays. The bast fibres are long and tough, arranged in tangential rows, and are separated without difficulty in very thin layers. The bark breaks with difficulty in a transverse direction, but is readily torn longitudinally. It is without odor, and without taste, with the exception of a very slight acridity and faint astringency. It bears a pretty close resemblance to mezereon bark, except in color and taste.

Constituents.—The bark contains *starch*, and when fresh, according to W. A. Taylor (1876), a *chromogen* which dissolves in alcohol with a pale-yellow color, gradually changing to a bright brownish-red. The same change takes place on keeping the bark for some time, which then yields a red tincture with alcohol. This substance was examined by Prof. Wayne (1872) and W. C. Staehle (1875), who regard it as of a resinous nature. The latter obtained about 8 per cent. of this substance, which is soluble in 14 parts of alcohol, 15 of chloroform, 23 of ether, and 122 of benzole; also in alkalies, from which solutions it is again precipitated by acids. The potassa solution diluted with water is of a sage-green tint. *Glucose* was likewise observed and the aqueous solution of the alcoholic extract contained a principle which gave a purplish-black precipitate with ferric chloride. C. C. Drueding (1877) obtained also a yellow resin soluble in petroleum-benzin, fixed oil, little tannin, and 6 per cent. of ash. (See also Extr. gossypii cortic. fluidum.)

Substitutions.—In 1875 a false cottonroot bark, evidently obtained from the root of a tree, was found in the market; it was one-eighth to one-quarter inch thick, pale-brown to rust-brown in color, covered with a soft fissured cork, inodorous and of a slight astringent afterwards bitterish and acrid taste, and yielded with alcohol a brown tincture. Its origin has not been ascertained.

Off. Prep.—Extractum gossypii radicis fluidum, *U. S.*

Medical Action and Uses.—The only virtue of cottonroot consists in its action upon the uterine system. It is reputed to have long been used by the female negroes of the Southern States for producing abortion. There appears to be little doubt that it acts like ergot upon the uterus, and that it displays its virtues in *dysmenorrhœa* and scanty menstruation, and particularly in *suppression of the menses* produced by cold. It is generally used in the form of decoction, prepared by boiling four ounces of the bark in two pints of water to the reduction of one-half. Of this a wineglassful is given every twenty or thirty minutes as an oxytocic. The fluid extract, which is officinal, is a more convenient form of the medicine, and may be prescribed in the dose of from thirty to sixty minims. Cotton-seed tea is a mucilaginous liquid which forms an appropriate drink in *dysentery*. The seeds have also been recommended as galactagogue, but the evidence of their value in this respect is insufficient.

GOSSYPIUM, *U. S.*, *Br.*—COTTON.

Bombyx, *Lana* (*Lanugo*, *s. Pili*) *gossypii.*—*Coton*, Fr.; *Baumwolle*, G.

The hairs of the seed of various species of Gossypium (see above).

Description.—Cotton consists of narrow thin-walled simple cells, which are about one-half to one and a half inch long, and appear under the microscope as flattened hollow and twisted bands, which are slightly thickened at the edges, finely and spirally striate and nearly cylindrical at the apex. It is without odor or taste, insoluble in the ordinary solvents, but soluble in ammoniacal solution of oxide of copper. It consists of nearly pure cellulose, and yields with nitric acid an explosive nitro-compound (see Pyroxylon), which is used in preparing collodion.

COTTON-SEED OIL.—By expressing the seeds from which the cotton has been removed, a dark-brown red fixed oil, containing a large percentage of albuminous matter, is obtained, which is bleached by treatment with alkalies and with sulphuric acid, and finally obtained of a pale-straw color and of a bland nut-like taste. W. H. Weatherly (1861) states that one bushel of shelled seeds yield about two gallons of crude oil, and that it may be used in some preparations as a substitute for the more expensive almond and olive oils, but not in the preparation of plasters. The oil is colored deep brown-red by concentrated sulphuric acid, and is not solidified when left in contact with solution of mercurous nitrate. Cotton-seed oil is stated to be used for adulterating olive oil, and even to be fraudulently substituted for it.

Surgical Uses.—Cotton has long been employed as a dressing for *burns*, *scalds*, *blisters*, *excoriations*, *erysipelas*, and other superficial inflammations. If the burn, scald, or blister be superficial, there is no better dressing. No other application more speedily and completely allays the pain of the injury. Even when the tissue of the skin is more deeply interested, the dressing is unsurpassed. It should consist of very thin layers of carded cotton, successively applied, and secured by a bandage, and should not be removed until the cure is complete. Carbolized cotton, that is, cotton impregnated with carbolic acid, has sometimes been employed. The fibre has been used as a substitute for lint, and also for sponge, after being thoroughly freed from the unctuous matter which in its natural condition renders cotton inapt for absorbing the secretions. As a dressing for *surgical wounds* cotton is said to be one of the most perfect preventives of *purulent infection*, as well as of prolonged suppuration, if it is properly applied in the manner described above. Washed cotton is especially applicable to this purpose, and is still more efficient if it has been washed in carbolic acid water.

GRANATI FRUCTÛS CORTEX, *U. S.*—POMEGRANATE RIND.

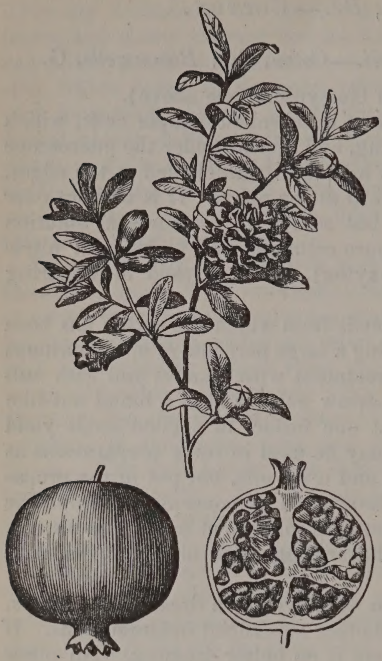
Cortex granatorum, *Cortex malicorii*, *Pericarpium granati.*—*Pomegranate bark*, E.; *Écorce de grenade*, *Cuir de pomme de grenadier*, Fr.; *Granatenschalen*, G.

The rind of the fruit of Punica granatum, *Lin.* Steph. and Church, Med. Bot., plate 57; Woodville, Med. Bot., 190; Bentley and Trimen, Med. Plants, 113.

Nat. Ord.—Granataceæ.

Origin.—The pomegranate is indigenous to Southwestern Asia from Northern India to Palestine; it has been cultivated from remote antiquity, and is now met

Fig. 84.



Punica granatum, *Lin.*

with in all subtropical countries. It is a shrub or small tree with lanceolate or oblong, pointed, entire and shining leaves, bearing one to three large crimson-colored flowers in the axils of the upper leaves, and producing a depressed globose fruit, of the size of an orange, irregularly divided by a transverse dissepiment into two unequal parts, the lower and smaller of which is about three celled, and the upper five to nine celled. The numerous seeds are oblong, irregularly angular from pressure, each invested with a fleshy pink-colored translucent coating. The rind of the fruit and the bark of the root are employed in medicine. The flowers and the sweet acidulous seed-coating are likewise used in oriental countries.

Description. — Pomegranate rind forms irregular curved fragments, which are about one line thick, externally somewhat tubercular and rough, of a brownish color with a yellowish or reddish tint, internally of a lighter color, marked with meshes indicating the depressions caused by the seeds. Some of the pieces are crowned by the thick, tubular, six- to nine-toothed persistent calyx, inclosing the remains of the style and numerous stamens. They break with a short granular fracture, are nearly devoid of odor, and possess a strongly astringent taste.

Constituents.—Examined by Reuss, pomegranate rind was found to contain about 28 per cent. tannin, 21 extractive, and 34 gummy matter. Bowman (1869) obtained 23.8 per cent. of tannin, which gives with ferric salts a blue-black precipitate. Flückiger obtained 5.9 per cent. of ash, calculated for the rind dried at 100° C. (212° F.), also some sugar.

Medical Action and Uses.—Pomegranate rind is an astringent, and, although possessed of some anthelmintic virtues, is employed in a gargle in relaxed states of the *fauces*, and in the treatment of chronic *diarrhœa*, *leucorrhœa*, passive *hemorrhages*, and cancerous and other *ulcers* of the uterus and rectum.

GRANATI RADICIS CORTEX, *U. S.*, *Br.*—BARK OF POMEGRANATE ROOT.

Cortex radicis granati, P. G.—*Écorce de la racine de grenadier* (*de balaustier*), Fr. ; *Granatwurtzelrinde*, G.

The bark of the root of Punica granatum, *Lin.* (See above.)

Description.—The bark of pomegranate root is met with in commerce in curved pieces or quills, 2 to 4 inches long, and scarcely ½ line thick, which are externally of a yellowish-gray color, marked with longitudinal or reticulate corky ridges, or irregular warts, and conchoidal depressions; the inner surface is smooth, finely striate, of a grayish or reddish-yellow color, frequently with fragments of the whitish wood adhering. It breaks with a short, granular fracture, which is of a greenish-yellow hue, and not perceptibly radiate in the inner layer; has no odor, and a purely astringent taste.

Constituents.—The principal constituent is tannin, of which Wackenroder (1824) found about 22 per cent., and which was recognized as peculiar by Stenhouse (1843). By fractional precipitation of the decoction with lead acetate, Ramdohr (1867) obtained some gallotannic acid, which could be converted into gallic acid, and *punico-tannic acid*, $C_{20}H_{16}O_{13}$, which is insoluble in alcohol and ether, reduces silver and alkaline copper solutions, and precipitates gelatin, tartar emetic, and ferric salts, the latter black. When boiled with dilute acids, it is split into sugar and *ellagic acid*, $C_{14}H_6O_8$. Stenhouse did not succeed in obtaining indications of the presence of gallic acid. Boutron-Charlard and Guillemette (1835) isolated *mannit*, which Latour de Trie (1830) had named *granatin*, and Guiart (1831) *granatomannit*. Cenedella (1835) obtained also sugar, mucilaginous and pectin compounds. Tanret (1878) has announced the discovery in the root-bark and stem-bark of an alkaloid, which, in honor of Pelletier, he proposes to call *pelletierina;* it is obtained by mixing the bark with milk of lime, displacing with water, and exhausting the percolate with chloroform. When pure it is colorless, oily, aromatic, and very soluble in water, alcohol, ether and chloroform; it precipitates the salts of most metals, and unites with acids to form crystallizable salts. 4 parts of the alkaloid were obtained from 1000 parts of the bark.

Adulterations and Substitutions.—The bark of the stem or branches, which is reputed to be less active, is often substituted for the root-bark; it closely resembles the latter, but has no conchoidal depressions upon the thinner cork, upon which, however, small lichens are not unfrequently observed. *The bark of boxwood* has an exfoliating corky layer, a yellowish-brown color, and a sweetish-bitter taste; its infusion is not affected by ferric salts. *Barberry bark* is readily distinguished by the bright yellow color of its tissue (see Berberis, p. 282).

Off. Prep.—Decoctum granati radicis, *Br.*

Medical Action and Uses.—The bark of the root has long been celebrated as an efficient *tænifuge* and *tænicide.* Its specific operation upon the system is manifested by giddiness, dimness of vision, drowsiness, faintness, numbness of the limbs, and even convulsions. The bark is most efficient when fresh. It is best administered in a decoction prepared as follows: Take two ounces of the fresh bark hashed, and let it soak overnight in a pint and a half of water, and then by gently boiling reduce it to a pint. Strain off the liquor, expressing the grounds, and give it lukewarm in three doses, at intervals of an hour, before the patient has broken his fast. If the first dose is vomited, the others should still be administered, and will generally be retained. No purgative or other treatment need precede or follow; it is, however, more prudent to administer an ounce of castor oil as soon as the gurgling and colic provoked by the decoction begin to appear. The bark of the trunk and of the branches of medium size has recently been shown to equal the bark of the root in medicinal virtues.

GRATIOLA.—HEDGE-HYSSOP.

Gratiole, Fr.; *Gnadenkraut*, G.

Gratiola officinalis, *Lin.* *Nat. Ord.*—Scrophulariaceæ.

Description.—The stem grows from a creeping rhizome to the height of 6 to 12 inches; has opposite, sessile, lanceolate, finely serrate, three-nerved leaves, and whitish or reddish two-lipped flowers, with yellow hairs in the tube. The plant is inodorous, and has a very bitter, somewhat acrid, taste.

Constituents.—E. Marchand (1845) obtained the white crystalline bitter principle *gratiolin*, which is little soluble in water and ether. Walz afterwards

(1852, etc.) proved it to be a glucoside, splitting under the influence of acids into sugar, into amorphous *gratiolaretin* and scaly *gratioletin.* Walz also isolated the reddish amorphous bitter principle *gratiosolin*, which is soluble in water and alcohol, and is likewise a glucoside. *Gratioloic acid* crystallizes in white scales of a fatty odor.

Physiological Action.—Experiments upon animals and observations upon man show that gratiola is a powerful local irritant, and that when taken internally it causes retching, vomiting, colic, purging, even bloody stools, and inflammation of the stomach and bowels, especially of the rectum. In enema it has occasioned so much pelvic irritation as to excite nymphomania, probably in predisposed persons. In one such case it is reported to have been fatal. In smaller, not purgative, doses it is said to be diuretic.

Medical Uses.—The chief, if not the only, use to which gratiola is applied in medicine is the treatment of *dropsy* by hydragogue purgation, as jalap, colocynth, and elaterium are employed. As it tends only to remove the dropsical effusion, and not its organic cause in the kidneys, heart, liver, etc., the chief point to be regarded is that the effects of the medicine should not be so violent as to induce the patient's collapse. Like other drastics, gratiola has been employed in the treatment of insane *melancholy* and in *mania;* and also to expel *intestinal worms.* For the last purpose the infusion has been used as an enema, prepared with half a drachm of the root in half a pint of water. As a drastic purgative the *dose* may be stated at from ten to twenty grains.

GRINDELIA.—GRINDELIA.

Nat. Ord.—Compositæ, Asteroideæ.

Description.—This genus consists of herbaceous or suffruticose perennials which are indigenous to the western part of North America and to Mexico. They are characterized by their heads being many-flowered; the ray-florets yellow, ligulate and pistillate; the disk-florets tubular, five-toothed and perfect; the involucre hemispherical, with the scales imbricated in many rows, often with squarrose tips; the receptacle flat and alveolate, and the akenes smooth and crowned with a pappus, consisting of a few rigid deciduous awns. The following species have attracted attention:—

GRINDELIA ROBUSTA, *Nutt.*—It is a polymorphous species, very smooth, pale, usually stout, with the leaves varying from broadly spatulate or oblong to lanceolate, the upper ones being often clasping, with a heart-shaped base; obtuse at the apex, and more or less sharply serrate. The akenes are from one to three-toothed at the apex, and have 2 or 3, rarely 5, awns for the pappus. The variety *latifolia* is the robust and broad-leaved form, the leaves being often 3 to 4 inches long. The variety *angustifolia* has rather fleshy and narrower leaves, the upper ones being nearly entire, and all narrowed at the base. The variety (?) *rigida* is more glutinous, the leaves rigid and coriaceous, some of them sharply serrate. All these plants have the tips of the involucral scales at length rigidly spreading. The plant is common along the Pacific coast and inland on the mountains.

GR. HIRSTULA, *Hook. and Arn.*, is pubescent or tomentose; the stem often reddish or purplish, the leaves varying between spatulate, oblong, and lanceolate, the upper ones clasping. It is met with along the coast northward to Puget Sound.

GR. GLUTINOSA, *Dunal*, is said to be introduced in sandy ground near the coast of California. It is glabrous, has the leaves rounded at the apex, the involucral scales with short tips, and the pappus of 5 to 8 rigid awns, with thin serrulate edges.

GR. SQUARROSA, *Dunal*, is found from Arctic America southward to California, Texas and Nebraska, and is very common on the plains. It is glabrous and viscidly resinous; the leaves rather rigid, glaucous and punctate, varying between spatulate-lanceolate and oblong, the upper ones sessile, partly clasping, rather obtuse, and finally toothed; the involucral scales with very long reflexed, squarrose, subulate points.

The plants have a balsamic odor, and a pungently aromatic and bitterish taste.

Constituents.—As far as may be judged from the sensible properties, these species contain volatile oil and resin, the latter not unfrequently coating the involucre and leaves, rendering them glutinous; hence the name *gum plant* commonly applied to them. A *fluid extract* may be prepared from it, using strong alcohol as the menstruum.

Medical Uses.—The herb of this plant is reported to be useful in *whooping cough* and *bronchitis*, and of singular efficacy in *asthma*. We have been informed of several cases occurring in aged persons, in which half a teaspoonful of the fluid extract afforded almost instantaneous relief. The *dose* for a child two years old is stated to be ten drops every two hours of the fluid extract. It is added that no unpleasant symptoms have been observed after large doses. Definite accounts of its action and uses are still wanting. It is alleged that the tincture or fluid extract of G. squarrosa has been used topically in cases of poisoning by rhus toxicodendron.

GUAIACI LIGNUM, *U. S.*, *Br.*—GUAIACUM WOOD.

Lignum guajaci, P. G.; *Lignum sanctum* (*vel benedictum, vel vitæ*).—*Lignum vitæ*, E.; *Bois de gayac* (*de gaïac*), Fr.; *Guajakholz, Pockholz, Franzosenholz*, G.

The heart-wood of Guaiacum officinale, *Lin.* Steph. and Church, Med. Bot., plate 90; Bentley and Trimen, Med. Plants, 41.

Nat. Ord.—Zygophyllaceæ.

Origin.—This, and the allied *Gua. sanctum*, Lin., are indigenous to the West Indian Islands and to the northern coast of South America. The former is about 40 feet high, has evergreen pinnate leaves with 2, rarely 3, pairs of smooth oval and obtuse leaflets, blue flowers, and 2-celled capsules, each cell containing one black seed. *G. sanctum* is smaller, has leaves with 4 or 5 pairs of oblong mucronulate leaflets, and a 4- or 5-celled fruit with red seeds. The wood of both species consists of heavy dark-colored heart-wood, surrounded by a yellowish zone of sap-wood, which is generally relatively broader in the second species.

Description.—The heart-wood is of a brown color, turning olive-green on exposure, and is composed of alternately darker and lighter zones, which form incomplete circles, and resemble annual rings, the tissue being well filled with resin. The central pith is quite indistinct, the medullary rays are very fine, the vessels scattered. The wood is very heavy, of specific gravity 1.3, hard, tenacious, and splitting very irregularly, caused by the much-interwoven wood-bundles. In the shops it is usually seen in the form of raspings and shavings, which should be free or nearly so from the lighter sap-wood. Guaiacum wood has a slight aromatic odor, which is more apparent on warming or rubbing it, and a somewhat acrid taste. The shavings acquire a dark blue-green color on being moistened with nitric acid or other oxidizing agents.

Constituents.—The wood contains from 20 to 25 per cent. of resin, which is the most important constituent, and yields about 3 to 4 per cent. of aqueous extract.

Off. Prep.—Decoct. sarsaparillæ (sarsæ) comp., *U. S.*, *Br.*; Syrup. sarsaparillæ comp., *U. S.*

GUAIACI RESINA, *U. S.*, *Br.*—GUAIAC.

Resina guajaci, P. G.; *Guaiacum.—Guaiacum resin*, E.; *Résine de gaïac*, Fr.; *Guajakharz, Guajak*, G.

The resin of the wood of Guaiacum officinale, *Lin.* (See Guaiaci lignum.)

Origin.—The resin is obtained partly as a natural exudation or from incisions, partly by setting fire to a billet of the wood which has been grooved or pierced lengthwise near the centre, the resin, as it melts, running from the opening.

Description.—The resin is in separate or agglutinated tears, varying in size from $\frac{1}{4}$ to 1 inch in diameter, or more generally in irregular masses, intermixed with fragments of wood and bark. It is of a greenish- or reddish-brown color, brittle, breaks with a somewhat conchoidal fracture having a glassy lustre, and is transparent in thin splinters. It yields a whitish powder, which turns rapidly green on exposure to the air, has the specific gravity 1.2, fuses at about 85° C. (185° F.), emitting an agreeable odor, suggesting that of vanilla, and at a higher temperature gives off irritating vapors. Its taste is not strong, but distinctly acrid. The resin is soluble in caustic potassa, and in nearly all the ordinary solvents for resins, except carbon bisulphide, benzol, and oil of turpentine. The solutions, as well as the powder, are colored green or blue by nitric acid, chlorine, ferric chloride, and other oxidizing agents; the same color is produced by ozone, and upon the inner surface of the paring of a raw potato. Guaiacum resin should be soluble in alcohol, leaving but a slight residue. Sometimes it is very impure, containing as much as 16 per cent. of wood and bark.

Constituents.—On boiling guaiac resin with milk of lime, *guaiacic acid* and *guaiac yellow* are dissolved. If the residue is treated with hot alcohol, the tincture evaporated, and this residue dissolved in hot solution of caustic soda specific gravity 1.3, the sodium salt of *guaiaretic acid* will crystallize on cooling, and the mother-liquor contains *guaiaconic acid* and *beta resin*, which, after the removal of the alkali, are separated by ether, in which the former only is soluble.

Guaiacic acid, $C_{12}H_{16}O_6$, was discovered in guaiac wood by Thierry (1841), and is present in very minute quantity; it crystallizes in white needles, is sublimable and soluble in water, alcohol, and ether. *Guaiaretic acid*, $C_{20}H_{26}O_4$, discovered by Hlasiwetz (1859), crystallizes in warts and scales, is of a faint vanilla odor, and is soluble in alcohol, ether, chloroform, benzol, etc., and sparingly soluble in cold water and ammonia. *Guaiaconic acid*, $C_{38}H_{40}O_{10}$, discovered by Hadelich (1862), is light brown, amorphous, insoluble in water, benzol, and carbon bisulphide, easily soluble in alcohol, ether, chloroform, and acetic acid; it acquires a transient blue color with oxidizing agents. Hadelich's *guaiacbeta resin* is a red-brown powder; his *guaiac yellow*, which was first noticed by Pelletier, has a bitter taste, and forms pale-yellow octohedra, which dissolve in oil of vitriol with a handsome blue color, and in alkaline liquids with a deep-yellow color. Hadelich obtained about 70 per cent. of guaiaconic acid, 10 per cent. each of guaiaretic acid and beta resin, and nearly 4 per cent. of gum, the remainder being the other constituents, including some impurities and 0.8 per cent. of ash.

On subjecting guaiaretic acid to dry distillation, a thick yellow oil is obtained consisting of *guaiacol*, $C_7H_8O_2$, which is a colorless oil of agreeable odor, forming with alkalies crystallizable salts; *guaiacene*, C_5H_8O, which is thin, oily, of a bitter almond odor and hot aromatic taste; and *pyroguaiacin*, $C_{19}H_{22}O_3$, which crystallizes in inodorous and tasteless scales, is colored green by ferric chloride, and is probably the substance to which guaiac resin owes its behavior towards oxidizing agents. By dry distillation guaiac resin yields *creosol*, $C_8H_{10}O_2$, in addition to the decomposition products mentioned; it and the allied guaiacol are colored green by caustic alkalies, and blue by alkaline earths; both have been observed in creasote. (See page 466.)

Off. Prep.—Mistura guaiaci, *Br.;* Pilul. antimon. comp. (hydrarg. subchlor. comp.), *U. S., Br.;* Tinctura guaiaci, *U. S.;* Tinct. guaiaci ammoniata, *U. S., Br.*

Physiological Action.—Guaiacum was for a long time regarded as a diaphoretic, because the syphilitic patients to whom its decoction was largely administered, and who were placed in conditions favorable to diaphoresis, sweated abundantly. It appears to be a stimulant whose action may be artificially directed to the skin. In excessive and concentrated doses it excites a burning pain in the throat and stomach, vomiting, purging, palpitation, congestion of the head, confusion of mind, and giddiness. These effects are produced by the decoction of the wood, and cannot, therefore, be due to the resin, which is insoluble in water; but from its strong taste and smell, it can hardly be without action upon the economy, and is, probably, like its congeners, a vascular stimulant.

Medical Uses.—Guaiacum is most renowned for the cure of constitutional *syphilis*, and the records of its use during nearly three hundred years were accepted as true until the scepticism of the nineteenth century condemned it. The vain and frivolous methods of using it which prevailed in recent times fully account for its want of success in the hands of modern physicians. While it was in vogue, the treatment by it was serious. The patient was obliged to observe a very strict regimen, to drink enormous quantities of a stronger and of a weaker decoction of the wood, to live upon a very sparing and simple diet, and in every manner to promote perspiration. The question of its efficiency has a very subordinate interest since the introduction of iodide of potassium. Like other vascular stimulants, guaiacum resin has been found efficient in promoting menstruation in all atonic conditions of the uterine system, and hence in *dysmenorrhœa* as well as in *amenorrhœa* of that origin. For the same reason, doubtless, it is a valuable remedy for chronic muscular *rheumatism.* For these purposes the ammoniated tincture is to be preferred. In simple *tonsillitis* and in *diphtheria* it is alleged to be very efficacious; but the former disease gets well spontaneously, and the evidence of the value of guaiac in the latter is inconclusive.

Guaiacum wood is prescribed only in decoction (see Decocta), simple or compound, of which the latter is most efficient. The resin may be given in doses of from ten to thirty grains. The guaiacum mixture (Br. Ph.) is a convenient form for its administration.

When the red coloring matter of the blood is brought into contact first with tincture of guaiacum and then with peroxide of hydrogen, the guaiacum is instantly turned blue. In the testing of suspected stains in this manner "it will be safe to say that if there is no bluing of the guaiacum resin in the presence of the peroxide, the mark or stain is not owing to blood." (*Taylor.*)

GUANO.—Guano.

Origin.—Guano consists of the partially decomposed excrements of the penguin and other sea-birds, which congregate in large numbers on the barren and uninhabited islands on the western coast of South America, and in other localities. It is principally exported from the islands off the coast of Peru.

Description.—It is in the form of crystalline or amorphous masses, or more frequently of an irregular powder having a grayish or pale-brown color, and an offensive, usually ammoniacal odor. Its spec. grav. is about 1.64; its reaction is mostly alkaline, though occasionally acid. It contains hygroscopic water varying between 6 and 20 per cent., which is expelled by the heat of a water-bath; when exposed to a higher temperature it blackens and burns, leaving a white ash varying in amount between 25 and 38 per cent.

Constituents.—The organic constituents of guano are chiefly *uric acid*, *ammonium urate*, and various oxalates. The chief inorganic constituents are phosphates of calcium, magnesium, and the alkalies, some sulphates, chlorides, and a very little sand; occasionally also ammonium carbonate. B. Unger (1845) discovered in guano the alkaloid *guania* $C_5H_5N_5O$, which has since been proved to exist also in the pancreatic juice of mammals; it forms a white crystalline powder which is insoluble in water, alcohol, ether, and ammonia, but soluble in acids and in potassa solution.

In estimating the value of guano as a manure, the amount of the following constituents, besides moisture and ash, is determined: ready-formed ammonia (present as ammonium salts), latent ammonia (generated in the soil from nitrogenous compounds), uric acid, and phosphates.

Medical Action and Uses.—Under the singular delusion that the ammonia in guano possesses some special mode of action different from that of officinal ammonium compounds, this substance was mixed with potter's clay, and used as a dressing for several *diseases of the skin*, and afterwards in baths and lotions. But it speedily exhibited the irritating effects proper to the salts of ammonia in common use, and is now quite abandoned. It will almost exceed belief that this bird-dung should have been introduced into a syrup and administered internally.

GUARANA.—Guarana.

Pasta guarana, P. G.—*Guarana*, Fr., G.

The powdered and prepared seeds of Paullinia sorbilis, *Martius*. Bentley and Trimen, Med. Plants, 67. *Nat. Ord.*—Sapindaceæ.

Origin.—Paullinia sorbilis is a climbing shrub, with pinnate leaves, composed of five oval-oblong toothed leaflets; small flowers in narrow spicate panicles, and pyriform beaked capsules containing one to three shiny blackish-brown subglobular seeds. It is indigenous to the northern and western provinces of Brazil.

Preparation.—The dry seeds are powdered, moistened by water or by exposure to the dew, and then kneaded into a kind of stiff paste, which is formed into globular or cylindrical masses; these are well dried near a fire, or by exposure to the sun.

Description.—Guarana is met with in subglobular, cylindrical, or elliptic cakes, which have an uneven surface, are hard, of a reddish-brown color, somewhat lighter internally, and breaking with an uneven, slightly glossy fracture. It has a peculiar slight odor, and an astringent and bitter taste.

Constituents.—Martius found guarana to contain starch, gum, a greenish fat, tannin which precipitates iron salts dark green, and a crystalline substance, *guaranin*, which was afterwards proved to be identical with *caffeina* (page 308), by Martius and by Berthemot and Dechastelus (1840). The latter obtained 4 per cent., Stenhouse 5.07 per cent. of caffeina. Saponin and volatile oil are likewise present in guarana.

Allied Plants.—Paullinia cupana, *Kunth*, which grows near the Orinoco River, has flattish, convex seeds; these are mixed with cassava and water, and subjected to fermentation, yielding a saffron-yellow liquid, which is used as a beverage.

Pharmaceutical Uses.—Kennedy (1876) proposed a *fluid extract of guarana* to be made as follows: 16 troyounces of guarana in moderately fine powder are moistened with a portion of a mixture composed of 8 fluidounces of strong alcohol and 4 fluidounces each of glycerin and water. The mass is packed in a glass percolator, the remainder of the mixture poured on, and the whole macerated for twenty-four hours, when it is displaced with diluted alcohol until exhausted. The first 12 fluidounces of the percolate are reserved, and the weaker portion evaporated to 4 fluidounces, and mixed with the reserved portion.

Physiological Action.—Among the conclusions drawn from his experiments by Mantegazza are these: that guarana, by its tannin, tends to retard putrefaction; that, like caffeine, it first excites frogs, then impairs their power of coördination, and ultimately throws them into spasms; and that it slows the action of their hearts. In various warm-blooded animals it produced similar effects, but it rendered the rabbit only somewhat dull and languid, and in dogs occasioned a sort of intoxication and excentricity of movement. According to the same authority, in man it gives rise to gayety, restlessness, increased quickness of perception and mental activity, wakefulness, a slight fall in the pulse-rate, impaired appetite, and vesical irritation. Like others, he associates guarana in the same category with maté, coffee, and tea, giving it the first place as a promoter of cerebral action. It is curious to contrast these definite and striking results with those of Dr. Macdowall, of West Riding Insane Asylum, Eng. He experimented upon himself and two male attendants, and it soon became evident to him that even in very large doses its effect upon the body in a state of health is almost, if not quite, inappreciable. It does not even cause constipation. In large doses it appears to dispel drowsiness after a late dinner, just as tea and coffee do.

Medical Uses.—The curative powers of this agent when first introduced appeared to be not less wonderful than in the case of other new remedies. It was a specific for diarrhœa and dysentery, gonorrhœa, leucorrhœa, and passive hemorrhages; was lauded as a stomachic tonic, and even put forward as remarkably efficacious in lumbago. Of all these virtues of the drug none survive; and the only affection in which it continues to be found useful is one which its congeners, tea, and especially green tea, and coffee, have never lost the reputation of relieving, *headache.* The particular forms of headache in which it is useful are the nervous sick headache which recurs frequently in the same person, and especially in females at the menstrual periods, and that which follows a debauch, when the head throbs, and the eyes are bloodshot. Like the other more popular remedies, guarana gradually loses its power over these attacks, and even appears to render them more frequent and severe. It may be administered in substance in the dose of from fifteen to sixty grains in powder; but in this form it is repulsive, and the doses mentioned are better given in infusion. The most efficient preparation is, however, the alcoholic extract dissolved in alcohol to form a tincture, in the proportion of one part to thirty. From two to five grains of the extract may be given at a dose. A fluid extract and a syrup have been made, and are convenient forms for administration.

GUTTA PERCHA, *U.S.*, *Br. Add.*—GUTTA PERCHA.

Gutta taban.—Gutta percha, Fr., G.

The concrete exudation, obtained by incisions, of Isonandra gutta, *Hooker.* Loudon's Journal of Botany, 1848.

Nat. Ord.—Sapotaceæ.

Origin and Preparation.—The taban is a stately tree, 60 to 80 feet high, with few branches, with evergreen oblong or obovate, entire, glossy, and underneath brownish leaves and small white flowers aggregated in little clusters near the top of the branches. It is common in the jungles of the Malay peninsula and of the Malayan Archipelago; it is now extinct in Singapore, having been destroyed in the collection of the juice. To obtain the gutta percha, the tree is felled, and circular incisions are made through the bark at distances of 6 to 12 inches along the whole trunk, from which the milky juice slowly exudes, and hardens on exposure. The yield from one tree is stated to be from 6 to 10 pounds; others claim a yield of over 20 pounds. Several other sapotaceous trees yield similar products.

Description.—Gutta percha is grayish or yellowish, frequently of a red-brown color, from fragments of bark and other impurities. It is hard and rather horny, in thin pieces somewhat flexible, between 45° and 60° C. (113° to 140° F.) sufficiently soft to be rolled into sheets, and quite plastic near the temperature of boiling water. Its specific gravity is about 0.98, but heavier than water after the removal of all air cavities (Payen). It is insoluble in water, alcohol, and fixed oils, dissolves in boiling ether, in chloroform, benzol, carbon bisulphide, and oil of turpentine. If purified by treatment with water and hydrochloric acid, and then repeatedly dissolved in boiling ether and washed with cold ether and alcohol, a fine white powder is obtained, of the composition $C_{20}H_{32}$, which is probably the composition of the recent juice (Baumhauer, 1859). It absorbs and combines with oxygen from the air, yielding an amorphous resin $C_{20}H_{32}O$, and a crystalline one $C_{20}H_{32}O_2$, which are contained in commercial gutta percha sometimes to the amount of 20 per cent. Subjected to dry distillation, various gases, water, and volatile acids are obtained, and two oils, one yellow, the other red-brown, both of the composition $C_{10}H_{16}$.

Pure gutta percha is inodorous and tasteless; ignited it burns with a bright flame.

Off. Prep.—Liquor gutta-perchæ, *U. S.*, *Br.*

Surgical Action and Uses.—The qualities which render this substance of value in the surgical and mechanical treatment of diseases, are its flexibility when warm, its firmness at ordinary temperatures, and its solubility in menstrua which do not alter its essential qualities. The facility with which it is bent and moulded, when warm, adapts it for use in making splints, whose size, shape, and weight can readily be changed. It has, in a great degree, supplanted the old and costly carved splint, to which, indeed, it is in all respects superior. Its lightness, firmness, smoothness, and unalterable character render it admirably adapted for the manufacture of syringes, specula, bougies, pessaries, stethoscopes, etc. Like collodion, the solution of gutta percha in bisulphuret of carbon or in chloroform may be used to retain the edges of incised *wounds* in apposition; and also as a protective of the *abraded skin* against mechanical injury or the *absorption of poisons*. The solution in chloroform, which is officinal, is a very convenient agent for protecting portions of the skin from the air, while it exerts a slight degree of compression which is modified by the elasticity of the film formed by the dried solution. It has been used with more or less advantage in the treatment of *lepra* and *psoriasis*, to prevent pitting in *smallpox*, and to limit the efflorescence in *erysipelas;* but the results are not conclusive of its utility. Gutta percha is also used as a convenient vehicle with which to incorporate certain caustics, as potassa and chloride of zinc, with the purpose of limiting and mitigating their action.

HÆMATOXYLON, *U. S.*—LOGWOOD.

Hæmatoxyli lignum, Br.; *Lignum Campechianum*, P. G.; *Lignum cœruleum.*—*Bois de Campêche*, *Bois d'Inde*, *Bois de sang*, Fr.; *Blauholz*, *Campecheholz*, G.

The heartwood of Hæmatoxylon Campechianum, *Lin.* Woodv., Med. Bot., plate 17. Bentley and Trimen, Med. Plants, 86.

Nat. Ord.—Leguminosæ, Cæsalpineæ.

Origin.—The logwood is indigenous to the shores of the Gulf of Campeachy and to other parts of Central America; it has been introduced into, and perfectly naturalized in Jamaica, St. Domingo, and other West Indian islands. The tree is 30 to 40 feet high, has many spreading crooked branches, alternate leaves with 4 pairs of obcordate leaflets, small yellow flowers in lax racemes, and two-seeded legumes. The tree is felled when about ten years old, the bark and light-colored sap-wood are removed, the red heart-wood alone entering commerce.

Description.—Logwood is met with in logs about three feet long, which, from exposure, are externally of a blackish-purple or red, internally of a brown-red color. Irregular concentric circles of darker and lighter red color, resembling annual rings, are observed upon cross-section; the vessels are distinct to the naked eye, the medullary rays very fine. The wood is heavier than water, specific gravity about 1.06, has a slight odor and a sweetish and astringent taste. In the shops, it is found in the form of chips and ground into a coarse powder, upon both of which a greenish lustre (*hæmatein*) is often observed.

Constituents.—Analyzed by Chevreul (1812), it was found to contain a little volatile oil, brown extractive containing tannin, fatty or resinous and glutinous matter, and a crystalline substance which he named *hæmatin*, but which is now more properly called *hæmatoxylin*. According to Erdmann (1842), it is best obtained from powdered extract of logwood, by mixing it with much sand and exhausting with ether; the ether is mostly recovered by distillation, and the residue mixed with some water and crystallized, a little sulphurous acid or solution of a sulphite being added to prevent oxidation; the yield is about 12 per cent. When pure, hæmatoxylin is $C_{16}H_{14}O_6$, and crystallizes with 1 or $3H_2O$ in colorless or pale yellow prisms, which have a strongly sweet taste of liquorice, acquire a red color on exposure to the light, and are freely soluble in hot water, in alcohol, and ether. The aqueous solution is slightly precipitated by solution of isinglass, and produces with baryta solution, lead acetate and copper salts white or grayish precipitates, which rapidly turn blue. Ammonia dissolves hæmatoxylin, the solution being rose-red, then purple, and finally blackish-red; the fixed alkalies produce similar solutions, and the color ultimately becomes yellowish-brown. The blackish ammonia solution contains *hæmatein-ammonia*, from which acetic acid separates *hæmatein*, $C_{16}H_{12}O_6$; this is soluble in alcohol and hot water, slightly so in ether, and forms a blackish-violet crystalline powder, having a green metallic lustre. Hæmatein-ammonia causes, in a warm solution of a small amount of alum and with ferric chloride, deep violet precipitates, with lead acetate, a brown one.

Off. Prep.—Decoctum hæmatoxyli, Extractum hæmatoxyli, *U. S.*, *Br.*

Medical Action and Uses.—Logwood is mildly astringent, and has been reputed to possess tonic virtues. It darkens the feces, sometimes turns the urine of a blood-red color, and gives it a sweetish taste. It constipates less than the pure astringents. It is used to check *diarrhœas*, *hemorrhages*, and *sweats;* its mildness renders it appropriate for infantile diarrhœas. Externally, it is said to display antiseptic and healing qualities in the treatment of *gangrenous* and *ill-conditioned sores.*

HAMAMELIS.—WITCH-HAZEL.

Hamamelis virginica, *Lin.* *Nat. Ord.*—Hamamelaceæ.

Description.—The witch-hazel is a shrub, from six to ten feet high, growing in damp woods and thickets in Canada and the United States. It has a rather crooked stem with flexuose branches which are covered with a smooth brown bark, the older bark being brown-gray and somewhat fissured, and internally whitish and smooth. The leaves are alternate, about four inches long, oval or obovate, slightly heart-shaped at the base, wavy-toothed on the margin, and, at least when young, stellately pubescent. The flowers are in clusters of three or four, with an involucre of three ovate leaflets, have a four-cleft calyx and four long linear, greenish-yellow petals, and appear in September and October, the nut-like two-celled and two-beaked capsule containing two black oily edible seeds, not ripening until September the next year.

The bark and leaves have been medicinally employed; the former has a bitter, astringent, and somewhat pungent taste; the latter are astringent and bitter.

Constituents.—H. K. Bowman (1869) ascertained the bark to contain 8.10 per cent. of tannin, which was determined by means of gelatin.

Medical Action and Uses.—The accounts published of the remedial virtues of witch-hazel seem to be as hard to accept as the popular faith in it as an infallible divining rod. Yet through the extravagant statements concerning it there runs a thread of reason; for all the conditions it is said to relieve are those of morbid excitement, such as *inflammations*, *congestions*, and *hemorrhages*, and even the action of the gravid uterus in threatened *miscarriage*. To the tannin it contains, and to a peculiar bitter principle, some of its alleged sedative virtues may be attributed. It was used by the American aborigines in decoction as a wash, and also in a poultice, for various local swellings and inflammations, including hemorrhoids and ophthalmia; and when the negro slaves endeavored to produce abortion by means of cotton root, miscarriage is said to have been prevented by the use of hamamelis. It may be used in a decoction made with an ounce of the bark to a pint of water, and given in wine-glassful doses every three or four hours, or oftener, according to the urgency of the case. We have known a decoction or infusion to be used as a lotion with apparent benefit in *crusta lactea*. A fluid extract is prepared of which the dose is a fluidrachm, diluted; and an ointment may be made with this extract evaporated to dryness, or with the fresh bruised bark boiled in lard. The last is used in hemorrhoids.

HEDEOMA, *U. S.*—HEDEOMA.

American pennyroyal, E.; *Herbe de pouliot américain*, Fr.; *Amerikanischer Poley*, G.

The leaves and tops of Hedeoma pulegioides, *Pers.* (Cunila pulegioides, *Lin.*, Ziziphora pulegioides, *Desf.*). Barton, Med. Bot., t. 41. Bentley and Trimen, Med. Plants, 200.

Nat. Ord.—Labiatæ, Satureieæ.

Origin.—Pennyroyal is an annual herb indigenous to North America from Canada, south through the United States. It grows in barren and sandy fields, on hills, and along the open border of woods, always in dry places.

Description.—It has an erect, obscurely quadrangular, branched and hairy stem, about ten to twelve inches high; opposite, shortly petioled, oblong ovate and obscurely serrate leaves, which are about one-half inch long and glandular dotted on the lower side, and axillary cymules of about three flowers. The calyx is tubular ovoid, hairy in the throat and somewhat two-lipped; the upper lip divided into three lanceolate teeth, the two lower teeth subulate. The corolla is small, not much exceeding the calyx, pale-blue, with purplish spots, two-lipped, the upper lip erect and emarginate, the lower lip spreading and nearly equally three-lobed. It has two sterile and two fertile somewhat exserted stamens, a bifid style, and produces four small smooth akenes at the base of the persistent calyx. It has a strong aromatic mint-like odor and a warm and pungent taste.

Constituents.—Its virtues depend upon the volatile oil (see Oleum Hedeomæ). Its other constituents are probably those generally found in plants of this natural order.

Mentha pulegium, Lin. (*Pulegium vulgare*, Mill.), the European pennyroyal, is a perennial herb, found in moist sandy localities in Central and Southern Europe. It has an ascending branching stem, oval obtuse and crenately serrate leaves, many-flowered axillary cymes, forming globular whorls and a purplish-colored four-lobed corolla. It resembles the former in odor, while the taste is somewhat bitter and acrid.

Hedeoma piperita, Benth., *Hed. Drummondii*, Benth., and some other species are found near the Rocky Mountains, and may possess similar properties.

Medical Action and Uses.—Hedeoma is an aromatic stimulant. It may be prescribed for the same purposes as other medicines of its class, *e. g.*, to relieve flatulent *colic* or *painful digestion*, to correct the nauseating or griping operation of certain purgatives, etc. For these purposes it is less eligible than mint, anise, etc. In the form of hot infusion it is much used to dissipate the congestions tending to diarrhœa and to inflammations of *throat* or *bronchia*, also in muscular rheumatism, etc., and, in conjunction with the hot hip- and foot-baths, to bring on retarded or suspended *menstruation*. An infusion made with half an ounce of the plant to a pint of water, may be given in the *dose* of two fluidounces or more, every hour.

HELENIUM.—Sneezeweed.

Helenium autumnale, *Lin.* *Nat. Ord.*—Compositæ, Senecionideæ.

Description.—The sneezeweed or *sneezewort* is an herbaceous perennial which is common in damp places in the United States, from Maine to Florida and Texas and westward to California and Oregon. It is of a grayish-green color, nearly smooth, three to five feet high, has a branching quadrangular, winged stem, and lanceolate serrate leaves which are pointed above and narrowed towards the base. The flower-heads are rather large, numerous, and have the involucral scales in two rows, the outer one foliaceous and reflexed; the ray-florets are ligulate, drooping, yellow, veined, and obtusely three-toothed at the apex. It flowers in August and September. The plant has scarcely any odor, and possesses a very bitter taste.

Constituents.—It was analyzed by F. J. Koch (1874), who found the usual principles met with in herbs. It contains but little tannin; the bitter taste is due to a principle which was obtained in an amorphous condition, is soluble in ether, alcohol, and boiling water, and on being boiled with dilute sulphuric acid, is resolved into sugar and an amorphous bitter substance having an acid reaction.

Allied Plants.—Hel. parriflorum, *Nutt.*, indigenous to Georgia, has lanceolate, nearly entire, scarcely decurrent leaves, and smaller flower-heads than the preceding.

Hel. tenuifolium, *Nutt.*, has numerous linear or filiform entire leaves and small flower-heads. It is found in the Southern United States from Georgia westward to Louisiana and Arkansas. The properties of these two species appear to be similar to those of the first.

Medical Action and Uses.—Common sneezewort is so called on account of the acrid qualities of its flowers and leaves, which when dried and powdered have been used as an errhine. H. tenuifolium is said to be very poisonous to animals, producing in them muscular twitchings, passing into violent convulsions, and terminating in death. In four negroes it produced spasms with more or less delirium and loss of consciousness (Galloway).

HELIANTHEMUM, *U. S.*—Frostwort.

Herbe de heliantheme de Canada, Fr.; *Canadisches Sonnenröschen*, G.

The herb of Helianthemum canadense, *Michaux*, s. Cistus canadensis, *Lin. Nat. Ord.*—Cistaceæ.

Frostwort, or *rockrose*, is a perennial herb indigenous to dry and rocky hills and sandy or gravelly soil of Canada and the United States south to Florida.

Description.—The rigid slender stem is about 12 inches high, has alternate elliptic or linear lanceolate entire leaves, which are nearly an inch long and woolly beneath. The flowers are of two kinds: the earlier ones, appearing in June, are solitary, stalked, with five unequal hairy sepals, and the same number of large yellow petals which unfold in sunshine only once. Somewhat later smaller apetalous and nearly sessile flowers make their appearance in axillary hoary clusters. The fruit is a three-valved one-celled capsule, which is shorter than the calyx, and contains few brown seeds. The herb, which varies much in habit, is inodorous, and has a bitterish astringent taste.

A closely allied species, *Hel. corymbosum*, Mich., is mainly distinguished by the petal-bearing and apetalous flowers being in crowded cymes near the top of the branches, the former being on elongated, filiform stalks. It grows from New Jersey southward, near the coast, in similar localities with the former.

It has received the names of *frostwort* and *frostweed* from the crystals of ice which shoot from the cracked bark of the base of the stem during freezing weather in autumn.

Constituents.—Frostwort has not been analyzed. It seems to contain tannin and a bitter principle.

Medical Uses.—The bitter, astringent, and slightly aromatic taste of this plant may explain its alleged utility in *scrofula*, *diarrhœa*, and secondary *syphilis*. A strong decoction of it is apt to produce vomiting, but is employed as a gargle in sorethroat, especially as it occurs in scarlatina, and also as a wash for prurigo. An extract is prepared which may be given in the dose of two grains.

HELIANTHUS.—Sunflower.

Helianthe, Grand soleil, F.; *Sonnenblume*, G.

Helianthus annuus, *Lin.* *Nat. Ord.*—Compositæ, Senecionideæ.

Description.—The sunflower is indigenous to tropical America, and cultivated in most civilized countries, in many of which it has become naturalized or grows spontaneously. It has a straight stem, from 10 to 15 feet high, which contains a large white pith. The leaves are alternate, petiolate, 10 inches long, broadly ovate or heart-shaped, three-ribbed, serrate and rough. The flower-heads are from 8 to 12 inches in diameter, with bright yellow ligulate ray-florets, and a flat brownish disk. The akenes are obovate-oblong, somewhat quadrangular, flattened, varying in color between whitish and black, at the base embraced by the chaff, and crowned with a very deciduous pappus of two chaffy scales. On being triturated with water, the kernels yield a bland emulsion.

Constituents.—Wittstein (1876) obtained from the fresh plant deprived of the fruit, 1.9 per cent. of ash, nearly two-thirds of which were carbonate of potassium, and from the fruit between 16 and 28 per cent. of fixed oil. The oil is pale yellow, limpid, bland, has the sp. gr. 0.962, and dries slowly on exposure to air. The kernels contain also, according to Ludwig and Kromayer, *helianthic acid*, $C_7H_9O_4$, which reacts dark green with ferric salts, is soluble in water and alcohol, and not precipitated by gelatin or ferrocyanide of potassium. The dried pith, according to John, contains 9 per cent. of potassium nitrate.

Allied Plants.—The numerous species of this genus have yellow flowers, rough, and frequently opposite leaves, and generally possess little odor. The following is occasionally cultivated for culinary purposes :—

Helianthus tuberosus, *Lin.*—Jerusalem artichoke, *E.*; Tompinambour, *Fr.*; Erdartischocke, *G.* Indigenous to Brazil. The tubers are thick, oblong, externally reddish, internally white, and resemble the artichoke in flavor, but are less pleasant. Examined by Braconnot, Payen, and others, they were found to contain 76 to 77 water, 14.7 sugar, 1 to 3 per cent. albumen, etc.

Medical Uses.—Sunflower is scarcely a medicinal agent. The oil may be used for many of the purposes of olive oil; the seeds for fattening poultry, and, after expression of the oil, for cattle; the pith of the stalk for making moxas; and the growing plant for drying damp soils, on account of its remarkable power of absorbing water.

HELLEBORUS, *U. S.*—BLACK HELLEBORE.

Raxix hellebori nigri, Radix melampodii.—*Ellébore noir,* Fr.; *Schwarze Nieswurzel, Weihnachtswurzel, Winterrose,* G.

The rhizome with the rootlets of Helleborus niger, *Lin.* Woodville, Med. Bot. 169; Bentley and Trimen, Med. Plants, 2.

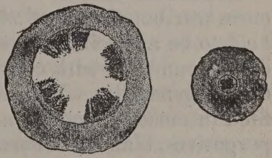
Nat. Ord.—Ranunculaceæ, Helleboreæ.

Origin.—Black hellebore, also called *Christmas rose*, is a native of Europe, and is met with in mountainous woods from Southern Germany and Central France southward to Italy and eastward to Greece. It flowers in winter, from December to March. The plant is acaulescent, has coriaceous, smooth, pedately seven to nine-lobed leaves, pale green, mottled with red, petioles and flower-stalks, and bears a single flower with five large white or pinkish sepals, and ten or more small greenish petals. The fruit consists of five to nine follicles, having the black shining seeds in two rows.

Description.—The rhizome, with branches, has an irregular knotty appearance, is 1 to 3 inches long, $\frac{1}{4}$ to $\frac{1}{2}$ inch thick; the branches annulate from leaf-sheaths, and terminating with a concave, or when more recent with a convex, scar. The numerous rootlets are long, but being very brittle, are always more or less broken off in the commercial article, about $\frac{1}{10}$ inch thick, longitudinally wrinkled, and like the rhizome of a brown-black color. The transverse section of the rhizome shows a thick brownish-gray bark occupying about one-sixth of the diameter, a somewhat thicker whitish pith, and 6 to 10 small wedge-shaped wood-bundles placed in a circle and separated by broad medullary rays. The rootlets have a thick bark, and a central slightly pentagonal or hexagonal wood. In the dry state, black hellebore has scarcely any odor; its taste is sweetish, then bitterish acrid.

In several European countries the rhizome and roots of Helleborus viridis, *Lin.*, are officinal and considered to be more efficacious. They are gathered together with the radical leaves, in the autumn or in early spring, before flowering; the leaves serve merely for identification, and are to be removed when used. The plant, which is indigenous to Central and Southern Europe, and grows wild on Long Island, produces its greenish flowers in March or April, and has pedately seven-lobed radical leaves with the lobes lanceolate acute and serrate. The rhizome is smaller, about 2 inches long and $\frac{1}{4}$ inch thick, above knotty, from the numerous stem-remnants, and annulate by the leaf-scars; the numerous nearly simple rootlets are 4 inches long, brittle, and usually broken off in the commercial article. In color, odor, and taste it resembles black helle-

Fig. 85.



Helleborus viridis, *Lin.*—Transverse section of rhizome and root.

bore. The transverse section of the rhizome shows a woody ring consisting of 4 broad and short wedges, each consisting of several smaller ones, and separated from one another by broad medullary branches, and inclosing a large pith. The rootlets have a thick bark and a central obtusely four-branched ligneous cord.

Constituents.—The two rhizomes appear to have the same constituents. Aside from those more generally met with, like resin, gum, etc., they contain *helleborin* $C_{36}H_{42}O_6$, discovered by Bastick (1852), and *helleborein*, $C_{26}H_{44}O_{15}$, discovered by Husemann and Marmé (1865); the latter principle is more abundant in black, the former in green hellebore. On exhausting the concentrated tincture with hot water, and filtering from the resin and oil, helleborin will crystallize; it is very poisonous, scarcely soluble in cold water, little so in ether and fixed oil, and freely soluble in alcohol and chloroform; its alcoholic solution has a burning taste, and it yields grayish amorphous and tasteless *helleboresin*, $C_{30}H_{38}O_4$, on being boiled with solution of zinc chloride. *Helleborein* is obtained from the decoction by precipitating with basic lead acetate, then with sodium sulphate, and finally with tannin; the latter precipitate is decomposed by oxide of lead, the dry mass exhausted with alcohol, the tincture concentrated and mixed with ether. It forms colorless nodules of minute needles, is readily soluble in water, less so in alcohol, and insoluble in ether, and has a sweetish taste and a poisonous action. Boiling with dilute acids converts it into sugar and greenish amorphous and tasteless *helleboretin*, $C_{14}H_{20}O_3$.

Hellebore contains no tannin; an organic acid present is probably identical with aconitic acid.

Adulterations.—Green hellebore, which should not be confounded with *veratrum viride*, is considerably higher in price than the black, and not often met with in the American market. The black hellebore of commerce is often mixed with the rhizomes and roots of other, mainly ranunculaceous plants, the most frequently occurring being *Actæa spicata*, Lin., which was formerly known as *Radix Christophorianæ s. aconiti racemosi;* the rhizome has a close resemblance to cimicifuga (see page 99), but merely the dimensions of black hellebore; its rootlets have the woody column arranged in four rays. The rhizome of *Adonis vernalis*, Lin., is subconical, almost simple, tufted above, not annulated, and has brittle rootlets with a cross-shaped wood. At one time we observed a black, forked, monocotyledonous rhizome of unknown origin offered as black hellebore.

Off. Prep.—Extractum hellebori, Tinctura hellebori, *U. S.*

Physiological Action.—Experiments on animals show that, however introduced into the system, hellebore is a violent gastro-intestinal irritant, producing vomiting and purging, with copious bilious evacuations, and killing through exhaustion and convulsions. On man, small and repeated doses of hellebore produce liquid alvine evacuations, and increase the menstrual and hemorrhoidal flows. In larger doses it causes vomiting, colic, spasm of the throat, thirst with heat in the abdomen, and exhaustion, cold sweats, and collapse with spasms. In the fatal cases reported nothing is said of its having purged.

Medical Uses.—The reputation of this medicine rests chiefly upon the cures attributed to it of *mania* and *melancholy*, for which it was, in some sort, held to be a specific. Possibly it may have been useful in cases of mental disorder connected with constipation and congestion of the liver and the abdominal organs generally. Yet the form of insanity which it seems most to have benefited in modern times is acute mania with febrile excitement. Like all drastic purgatives, black hellebore is sometimes curative of *amenorrhœa* either of the congestive or the atonic form; and is often a palliative of *ascites* by removing more or less of the dropsical fluid through the bowels. For this purpose it is inferior to jalap. The *dose* of the powdered root, as a purgative, is from five to twenty grains. A decoction may be prepared by boiling sixty grains of the bruised root in a pint of water; of which a fluidounce may be given every two or three hours until it operates.

HEMIDESMI RADIX, *Br.*—HEMIDESMUS ROOT.

Indian sarsaparilla, Nunnari, E.; *Racine de hemidesmus,* Fr.; *Hemidesmus-Wurzel,* G.

The root of Hemidesmus indicus, *P. Br.* (Periploca indica, *Willd.;* P. emetica, *Retz.;* Asclepias pseudo-sarsa, *Roxb.*). Wight, Icon. Plant., Ind. Orient., ii. p. 594; Bentley and Trimen, Med. Plants, 174.

Nat. Ord.—Asclepiadaceæ.

Origin.—This slender climbing shrub is a native of the Indian peninsula, in all parts of which it grows in uncultivated places. It has opposite entire leaves, varying between linear-lanceolate and ovate, the broadest being on the upper branches; axillary clusters of small purple flowers, long linear follicles and numerous seeds with tufts of slender hairs.

Description.—The root is met with in pieces about 6 inches long and $\frac{1}{4}$ to over $\frac{1}{2}$ an inch thick, cylindrical, tortuous, longitudinally wrinkled, and transversely fissured, forming annulations. It is covered with a thin dark-brown corky layer, followed by a whitish mealy thin bark, containing in its inner layer scattered laticiferous vessels. The cambium line is dark, wavy, and the wood yellowish, with narrow medullary rays, which are best observed in the thin roots. Hemidesmus root has an agreeable odor, suggesting that of tonka, and a sweetish, slightly acrid, not unpleasant taste.

Constituents.—The root contains starch, and in the suberous layer some tannin. Scott (1843) obtained a stearopten by distillation with water. Its other constituents are unknown.

Off. Prep.—Syrupus hemidesmi, *Br.*

Medical Action and Uses.—In India, whence it was introduced into England, this medicine has some reputation for efficacy in the constitutional disorders supposed to be benefited by sarsaparilla. But its syrup, which is also officinal, is, like the syrup of sarsaparilla, chiefly used as a flavoring ingredient of mixtures.

HEPATICA, *U. S.*—LIVERWORT.

Herbe de hépatique, Fr.; *Edelleberkraut,* G.

The leaves of Hepatica triloba, *Chaix* (Hep. nobilis, *Moench;* Anemone hepatica, *Lin.*).

Nat. Ord.—Ranunculaceæ, Anemonideæ.

Origin.—A perennial, acaulescent herb, flowering in March and April, and indigenous to Europe, and North America south to Georgia, growing in shady woods. The flowers are on villous scapes 4 to 6 inches long, and have a three-leaved involucre, and 6 to 9 petal-like, blue or purplish, or sometimes white sepals. The radical leaves are the portion used.

Description.—The leaves are subcoriaceous, smooth, dark-green, and shining above, paler beneath, broadly heart-shaped or somewhat kidney-shaped in outline, and divided into three lobes, which are obtuse or rounded (*Hep. Americana,* De C.), or pointed (Hep. acutiloba, *De C.*). A similar distinction is also observed in the involucral leaves, the two forms being probably mere varieties of one species, the acute-lobed preferring a northern exposure. The leaves are inodorous, and have an insipid, slightly astringent, and bitterish taste.

Constituents.—As far as may be judged from the sensible properties, liverwort does not appear to contain any important characteristic principle. Mucilage, sugar, and a small amount of tannin are present.

Medical Action and Uses.—It passes for being tonic and deobstruent. It once had a transient vogue in the treatment of chronic *bronchitis* and *phthisis.* But its medicinal value is very small, and hardly entitles it to a place in the materia medica.

HERACLEUM.—COW-PARSNIP.

Heracleum lanatum, *Lin.* *Nat. Ord.*—Umbelliferæ, Orthospermæ.

Description.—The cow-parsnip, also called *masterwort*, is a woolly perennial herb, growing from 5 to 10 feet high in most of the northern and middle parts of the United States, westward to the Pacific. The root is many headed, fleshy, nearly simple, or composed of many thinner branches, half an inch or less in diameter, brownish-yellow externally, white internally, with a rather thick bark, containing resin-cells. The leaves are large, ternately dissected, on very broad and sheathing petioles, the segments often 10 inches long, the middle one usually three-lobed. The umbels are from 12 to 15 inches broad, with an involucre of oblong lanceolate leaves, and involucels composed of 5 or 8 lanceolate, slender, acuminate leaves. The flowers are white. The fruit is one-third of an inch long, oval, flattened on the back, broadly winged on the margin, each mericarp with 5 slender ribs, the lateral ones being close to the margin, and in the upper half with 6 clavate oil tubes, two of which are on the commissure. All parts of it have a rank odor and a pungently acrid taste. The root, leaves, and fruit have been employed.

HERACLEUM SPHONDYLIUM, *Lin.*, the cow-parsnip of Europe and Northern Asia, is a similar but smaller plant, and possesses similar properties.

Constituents.—These plants appear to contain volatile oil and resin; their acrid principles have not been investigated.

Medical Action and Uses.—In their fresh state the leaves applied to the skin may produce vesication, and have been used as counter-irritants. Some of the European species are still more irritant, and contain a juice which has been applied to warts as an escharotic. The American plant has been used in *epilepsy* apparently depending upon gastro-intestinal irritation. It was given both in substance and in infusion, and was thought to correct *dyspeptic* disorder. A drachm of the root, or its equivalent in infusion, may be taken several times a day.

HEUCHERA, *U. S.*—ALUM ROOT.

Racine d'heuchère d'Amérique, Fr.; *Amerikanische Sanickel-Wurzel*, G.

The root of Heuchera americana, *Lin.* *Nat. Ord.*—Saxifragaceæ.

Origin.—This is a perennial herbaceous plant, with a tuft of orbicular-heart-shaped, slightly lobed, and crenately-toothed hairy leaves, and glandular hairy scapes about 2 feet high, bearing loose panicles of small flowers with short, white, narrow petals and exserted stamens and styles. It is common in rich woodlands of the United States from the New England States west to Wisconsin and the Mississippi and south to Georgia. It flowers in June, and the root is probably best collected in September.

Description.—The root is about 6 inches long, about $\frac{1}{2}$ inch thick, with several short cylindrical heads terminating with a concave scar, tapering, and somewhat branched below and beset with some thin radicles. In its fresh state it is fleshy; when dry, irregularly shrivelled, tuberculate, the brittle fibres usually broken off. It is externally of a purplish-brown color, has a thin bark, and a thick meditullium of a pale reddish, sometimes brownish, tint, and breaks with a short, somewhat spongy or granular, not fibrous, fracture, often showing internal cavities. It is inodorous, and has a strongly astringent, slightly bitterish taste. The rootlets agree with the main root in color and taste, but have a thick bark and thin spongy centre.

Constituents.—The root has not been fully analyzed. H. K. Bowman (1869) found it to contain from 18 to 20 per cent. of tannin.

It is not unlikely that the root of *Heuchera villosa*, Mich., and probably other species, may possess virtues similar to those of the officinal.

Medical Action and Uses.—Alum root, as its name implies, is astringent. In decoction it is sometimes used in domestic medicine as a remedy for *diarrhœa* and *menorrhagia*, and as an application to *ulcers*, *hemorrhoids*, etc.

HIERACIUM.—HAWKWEED.

Épervière, Fr.; *Habichtskraut*, G.

Nat. Ord.—Compositæ, Cichoraceæ.

Description.—The following species have been used:—

HIERACIUM VENOSUM, *Lin.* *Rattlesnake-weed.*—It is a perennial herb, common in dry woods and plains of North America, with oblong-obovate, purple-veined, entire, and scarcely petiolate radical leaves about 2 inches long, and with a naked or one-leaved smooth scape about 18 inches long, bearing a loose paniculate corymb of yellow flower-heads, which have slender peduncles, a nearly cylindrical involucre, and linear akenes with a tawny, fragile, bristly pappus. The plant is inodorous, and has a somewhat bitter and acrid taste.

HIER. GRONOVII, *Lin.*, likewise a North American species and growing in similar localities, has a wand-like simple stem which is leafy and hairy below. The leaves are petiolate, lance- or obovate-oblong; the peduncles slender and, like the involucre, glandular-pilose. The akenes are tapering at the summit. This and the next species are sometimes used for toothache.

HIER. SCABRUM, *Lin.*—It is stouter than the preceding, rough hairy, more branched; the involucre glandular-hirsute, and the akenes not taper-pointed.

HIER. PILOSELLA, *Lin.* Piloselle, Oreille de souris, *Fr.;* Mäuseöhrchen, *G.*—A European plant with white hairy leaves about an inch long, and a hairy, naked, or one-leaved scape. Its taste is bitter and astringent.

HIER. MURORUM, *Lin.* Pulmonaire des Français, *Fr.;* Gelbes Lungenkraut, *G.*—It has ovate, pale green, sometimes spotted radical leaves, and a hairy, few-leaved stem about 3 feet high, bearing several yellow flower-heads. Its taste is slightly bitter and astringent. It has been used as a vulnerary and in pectoral complaints.

Medical Uses.—Although hawkweed has been used in several diseases, such as scrofula and chronic catarrh, its chief claim to notice rests on its reputed power of curing the bites of venomous snakes. The late Dr. Griffith in his *Medical Botany* relates the following: "Some years ago a person brought a collection of rattlesnakes to this city, and professed to be in possession of a certain cure for the symptoms arising from their bite, which he offered to divulge for a moderate compensation. This being paid him, he suffered himself to be bitten several times, and, after the poisonous effects had displayed themselves, was completely relieved by taking a few ounces of the decoction of a plant which was identified as *Hieracium venosum.* The same snake was suffered to bite a small puppy, which died from the poison in about five hours. These experiments were made in the presence of a number of distinguished medical and scientific persons."

HIPPOCASTANUM.—HORSECHESTNUT BARK.

Cortex hippocastani, Cortex castaneæ equinæ.—*Écorce de marronnier (chataignier) d'Inde*, Fr.; *Rosskastanienrinde*, G.

From Æsculus hippocastanum, *Lin.*

Nat. Ord.—Sapindaceæ, Hippocastaneæ.

Origin.—The horsechestnut is a well-known stately tree which is a native of Persia and Northern India, but is at present cultivated as an ornamental tree, and grows spontaneously in many countries of the temperate and sub-tropical zones. The bark of the smaller branches is the part employed. The seeds, which have a bitter and acrid taste, contain a large quantity of starch, which may be obtained pure by prolonged washing with water.

Description.—The bark is thin, externally of a gray color, has some small scattered warts, and shows opposite leaf-scars, which have the lower rounded margin marked with 5 or 7 small warts. The inner surface is smooth and whitish, the internal color brownish. The inner bark is rather tough, breaks with a fibrous fracture, has a slight odor, and a bitter astringent taste.

Constituents.—The tannin of horsechestnut bark colors iron salts green. Besides some fat, chlorophyll, and other common compounds, the bark contains *æsculin*, $C_{15}H_{16}O_9$, and *fraxin (paviin)*, $C_{32}H_{36}O_{20}$, both principles being inodorous, of a slight bitter taste, and showing a blue fluorescence when dissolved in water, particularly in the presence of alkalies. Æsculin is obtained by precipitating the decoction with solution of alum and excess of ammonia, evaporating the filtrate to dryness, exhausting the residue with boiling strong alcohol, and recrystallizing. It forms small white needles containing $2H_2O$, which are insoluble in ether, and have an acid reaction upon litmus. On boiling with dilute acids it is split into glucose and *æsculetin*, $C_9H_6O_4$, which dissolves in alkalies with a golden-yellow color, and colors ferric salts dark green. Baryta solution produces the same decomposition, and then yields *glucinic*, *apoglucinic*, and *æsculetinic acids*. Fraxin is obtained by precipitating the alcoholic tincture with an alcoholic solution of acetate of lead, diffusing the precipitate in water, decomposing by sulphuretted hydrogen, evaporating over sulphuric acid to dryness, and removing the tannin by washing with ice-cold water; it dissolves in alkalies with a yellow color, colors ferric chloride green, and then produces a lemon-yellow precipitate.

The integuments of the seeds contain some æsculin and *quercitrin*, which are likewise present in the flowers, but the leaves contain yellow *queræscitrin*. The cotyledons contain, besides starch, some fixed oil, *Oleum hippocastani*, which was obtained by Genevoix (1859) to the amount of $\frac{1}{10}$ per cent. by extracting with ether; it is of a yellow color, has a turnip-like odor, and congeals near the freezing point of water. *Argyræscin* and *aphrodæscin* are two amorphous acrid bodies, discovered by Rochleder (1862), which are insoluble in ether, soluble in alcohol, and yield with water solutions foaming like saponin; the latter is precipitated by baryta water, and boiled with alkalies yields butyric and amorphous *æscinic acids;* the former is a glucoside.

ÆSCULUS PAVIA, *Lin.* *Red buckeye.*—E. C. Batchelor (1873) obtained from the testa tannin, 3 per cent. of resin, a tasteless crystalline principle, and coloring matter. The cotyledons were found to contain 5 per cent. of greenish-brown fixed oil, 2½ per cent. cane-sugar and syrup, and a brownish, bitter, and acrid glucoside, different from argyræscin and apparently poisonous.

Medical Uses.—It is asserted that the bark of the branches, and also the æsculin obtained from it, have cured *periodical fevers* in which even quinia failed. The same statement is made respecting numberless bitter vegetable products. It is also stated that æsculin will cure *neuralgia*. These medicines are of little value. A decoction may be prepared with one or two ounces of the bark in a pint of water, boiled for ten minutes. *Dose*, a wineglassful. Æsculin may be given in doses of five or more grains.

HIRUDO, *Br.*—LEECH.

Hirudines, P. G.—*Sangsue*, Fr.; *Blutegel*, G.

Sanguisuga medicinalis, *Savigny*, and Sang. officinalis, *Sav.*
Class Vermes; *Ord.* Annulata; *Subord.* Apoda; *Family* Hirudinea.

Description.—Leeches are invertebrate animals with an elongated, roundish, or somewhat flattened body, which has numerous transverse wrinkles, and is generally attenuate towards both ends; the posterior one always terminates by a broad and muscular disk, by means of which the animal fastens itself upon objects. The blood-sucking leeches have their anterior end or head likewise terminated by a narrower disk, in the centre of which is placed the mouth containing three jaws, which are provided with two rows of numerous-pointed teeth, and are mutually inclined at an acute angle, so as to make a triangular incision through the skin. Respiration is carried on through small apertures or *stigmata*, arranged in two rows on the abdominal surface, and found at every fifth ring. Leeches are hermaphrodites, but mutually impregnate each other. Several pairs of testicles are located in the fore and middle part of the body; the filiform penis is projected from an abdominal orifice about one-third distant from the head, and the female organs with two ovaries have their aperture or vagina five rings below the penis. The ova are deposited near the edge of the water, invested with a kind of a jelly or mucus, which contracts into a capsular or cocoon-like body, having a spongy appearance, and containing about 10 or more eggs. Leeches are aquatic animals, and swim with a vertical undulating motion.

Sang. medicinalis, Sav. (*Hirudo medicinalis*, Lin.), has the back of an olive-green color and marked with six longitudinal pale rust-colored stripes, which are mostly spotted with black. The belly is greenish-yellow, more or less spotted with black, occasionally to such an extent that the prevailing color is black. The animal is indigenous to Central and Northern Europe, and is known in commerce as the *Swedish* or *German leech.*

Sang. officinalis, Sav. (*Hirudo provincialis*, Carena).—The back is green or blackish, marked with six longitudinal rusty-red stripes, dotted with black. The belly is olive-green, unspotted, but marked with a black stripe on each side. This leech is indigenous to the southern part of Europe, and is known in commerce as the *Hungarian leech.* There are several varieties of this species, differing from one another by modifications of the dorsal stripes.

Several other species of Sanguisuga are found in Southern Europe and occasionally employed, but are not an article of commerce. Leeches are generally kept in ponds by the wholesale dealer and even cultivated in this manner. They are usually transported imbedded in moist turf.

The *American leech*, Hirudo decora, *Say*, which draws less blood, is sometimes employed. Its back is of a dark green color, and marked with one row of orange-brown, and two lateral rows of black spots; the belly is of a light orange-brown color spotted with black.

Preservation.—Leeches require some attention to keep them healthy and in good condition. They are kept in clean river water, in a glass jar covered with a linen cloth, and put in a shady place which is free from ammoniacal and other noxious vapors. The temperature is best kept between about 10° and 20° C. (50° and 68° F.), sudden changes being carefully prevented. As soon as the water begins to get turbid or colored, the leeches should be placed in clean water of the same temperature, and the jar well cleaned from the slimy deposit, which is caused by the transparent epidermis being thrown off every four or five days. To facilitate its removal, some material is often put into the jar through which the leech may draw itself, and which, by retaining this slime, will tend to keep the water clean; charcoal, pebbles, clay free from lime, moss, and Irish moss have been recommended and found advantageous for the purpose, and apparatuses have been constructed in which leeches may be kept on a bed of material which permits of a frequent renewal of the water without handling the leeches. If they are kept in moist earth, turf, or clay, this should be examined from time to time and dead animals removed. The water should be changed at least once a week, and oftener in warm weather. It will be observed that the conditions for the preservation of leeches are pure air, pure water, and a pretty uniform temperature. Leeches are subject to several diseases which may become epidemic, and are recognized by an excessive separation of mucus, ulcerations, tumors, or a flaccid appearance of the body; when thus attacked, they should be at once removed from the healthy ones, and placed in a separate vessel in clean water upon a layer of charcoal.

Medical History.—Leeches have been used from time immemorial in Asia, but particularly in Bengal, where they are considered the best means of local depletion. They are especially preferred for Rayahs, for women and timid persons, and for the very young and very old (Wise). In Greek medicine, they were not apparently known until a late date; the first mention of them being made by Themison, who lived in the century preceding the Christian era. They are scarcely alluded to by Pliny, who flourished a century later in Rome; but subsequently their uses are described by all the Latin and Arabian medical writers, as well as the mode of applying and preserving them, and the accidents that may occur from their getting into the throat or stomach.

Medical Action and Uses.—Depletion by leeches is by no means identical with taking blood by venesection, even in its action upon the general system, for the rapidity of the loss in the one case, and its slowness in the other, render the effects quite different; in the former, the impression is direct and sudden, in the other, indirect and gradual. In their local actions, the difference is still more evident, for while in the one case the whole of the blood is despoiled to make a limited and local impression, in the other, the effect is produced by a very small loss of blood. It must be remembered that the circulatory apparatus is not a mere hydraulic machine, but that the bloodvessels, and especially the capillaries, are endowed with vital contractility which may be modified within a limited area and excited by a local irritation. All active congestions and inflammations are, in their origin, local diseases, and are therefore more or less amenable to local treatment, of which one of the most powerful forms is the abstraction of blood, the essential pabulum of all inflammatory processes. Hence the utility of leeches in inflammations in whose immediate neighborhood these animals can be applied; it is not so intelligible when they operate upon the surface of the body immediately over inflamed organs which have no direct communication with the skin, as in pneumonia, metritis, gastritis, enteritis, meningitis, etc. The mere loss of so small a quantity of blood as they abstract from the general circulation, does not appear to be a satisfactory explanation. The superiority of leeches over cups, as means of local depletion, consists not only in the advantages referred to above, but also in their being applicable to various parts to which cups could not be applied, as the eye, the mouth, the anus, vagina, etc.

Large leeches should be used only when blood is to be freely abstracted, and when the part is not very sensitive or exposed. The wounds they make are apt to be ecchymosed and to leave visible scars. Small leeches are always preferable for application to the face and neck, for the reasons just given, and also because the bleeding from their wounds is more easily controlled. The number to be used will depend upon the size of the leeches, the quantity of blood to be abstracted, and the vascularity of the part. The part to which the leeches are to be applied should be thoroughly washed with warm water, and even with hot water, if it is not sufficiently vascular. Sometimes a hot poultice is applied to stimulate the skin. In order to induce the animals to bite, it is customary to moisten the part with sugared water or milk, or to rub it with a piece of raw meat; or the leecher pricks the part with a fine needle and smears the blood over the skin; or he draws from his own finger a drop of blood for this purpose. A common method of applying leeches to a free surface is to put them in a small tumbler or wineglass, and invert it over the part. Others place the creatures in a cup, and direct them, as they crawl over its edge, to the part where they should bite. For application to the nostril, throat, or vagina, the leech may be inclosed in a tube open at either end.

A healthy leech of medium size will draw from one to two fluidrachms of blood, and as much more will usually flow after the leech has fallen. When a strong and rapid impression is to be made by leeches, the number applied at once should be considerable; but when a slow but continuous action is desired, a succession of them may be used. This is often desirable in cases of traumatic and other inflammations within the cranium. It is an ancient custom, instead of applying many leeches, to apply only one or two, or a comparatively small number, and when they are nearly gorged to puncture their bodies near the tail with a needle or fine lancet, when they will often continue to draw blood indefinitely. In any case, the punctures will continue to bleed if they are kept sponged with warm water. Sometimes there is a difficulty in stopping the flow of blood, particularly if the wound is in the epigastrium, the neck, or some other part where firm pressure cannot readily be made. The various hæmostatics may here be applied, several of them being of common use in domestic medicine, such as scraped lint, burned rag, agaric, cobweb, powdered rosin, India rubber softened by heat, vinegar and water, etc. If these fail, or, in their stead, a saturated solution of alum in hot water may be applied on lint, while the liquid is hot; or lint saturated with a solution of perchloride of iron, or of tannic acid; or the lunar-caustic pencil, reduced to a fine point, may be inserted in the wound; or, finally, the point of a red-hot knitting-needle may be used in the same way. In all these cases, the action of the hæmostatic should be aided by pressure with the hand, or with a small clamp or pincers made for the purpose, or by passing a needle through the skin, including the wound and surrounding it with a ligature in the form of a figure of eight.

Small leeches are sometimes taken in drinking water, and attach themselves to the fauces or pharynx, and have even penetrated into the larynx and fatally obstructed it. A strong gargle of salt and water usually suffices to make them quit their hold, and vinegar will have the same effect. These liquids have been used, as also has wine, when leeches have been swallowed; but the creatures would probably be unable to live under the action of the gastric juice. In some cases, and especially when the leech has entered the larynx, its presence has been discovered by the laryngeal mirror; and in one case, at least, laryngotomy had to be performed for its removal.

When leeches have been gorged with blood, they are not, if left to themselves, fit to be used again for several months. But by placing them in a weak solution of salt and water, or of vinegar and water, they may be made to disgorge the blood they have swallowed, and they soon regain their vigor if they are then placed in fresh water. They may also be emptied of their blood by stripping them. Such leeches are more subject to disease, and they should be kept separate from the others.

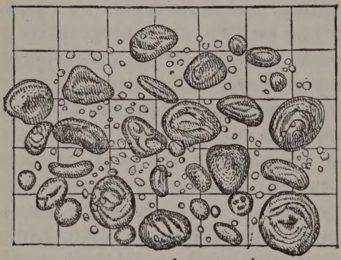
HORDEUM, *U. S.*—PEARL BARLEY.

Hordeum decorticatum, Br.; *Hordeum perlatum.—Orge perlé*, Fr.; *Perlgerste, Perlgraupen*, G.

The husked seeds of Hordeum distichon, *Lin.* *Nat. Ord.*—Graminaceæ.

Origin.—Barley is probably indigenous to Western Asia, and has been cultivated from a very early period. It is now raised in most parts of the temperate zones, and in Europe within the Arctic Circle. Besides the two-rowed or long-eared barley, *Hord. vulgare*, Lin., or spring barley, and *H. hexastichon*, Lin., or six-rowed barley, are the principal species cultivated. The fruit of these species is used indiscriminately in the preparation of malt, and, when in suitable mills deprived of the integuments and rounded at the ends, constitutes the officinal pearl barley.

Fig. 86.



BARLEY (HORDEUM)

Starch granules.

Description.—Pearl barley is nearly globular, of a white color and mealy appearance, with the exception of a groove in which fragments of the integuments are present. The larger pearls still contain externally a layer of gluten; the smaller ones consist altogether of the mealy albumen, and are formed of a cellular tissue filled with starch granules, which resemble wheat starch, and are made up of small and large grains with few intermediate ones. They are irregularly circular or elliptical in shape, with the nucleus or hilum rarely perceptible, and the layers indistinct. Pearl barley is inodorous, and has an insipid taste.

Constituents.—The average of the various analyses made by different chemists gives to barley 60 to 68 per cent. *starch*, 12 to 16 per cent. of *protein compounds*, consisting of gluten and albumen, 2 to 3 per cent. of *oil*, the same of *ash*, 10 to 14 per cent. of *moisture*, and 8 to 12 per cent. of *cellulose.* Lermer (1863) found in exsiccated barley also 6.6 per cent. of *dextrin*, and traces of tannin and bitter principle; and Lintner (1868) a little cholesterin. Proust's *hordein* was proven by Braconnot and Guibourt to be a mixture of cellular tissue, starch, and gluten. Beckmann's (1855) *hordeic acid* is evidently a fatty acid liberated by the oil of vitriol used in its preparation.

Off. Prep.—Decoctum hordei, *U. S.*, *Br.*

Medical Uses.—From the earliest times barley has been used not only as food, but to prepare drinks for the sick, especially in febrile diseases and in pulmonary and urinary disorders. It is now seldom employed externally, but continues to be given internally, and for the same purposes as of old. The addition of honey makes barley-water more efficient in *bronchial affections* and *sore throat;* forms of preparing it are given under Decoctum hordei.

HUMULUS, *U. S.*—HOPS.

Lupulus, Br.; *Strobili humuli s. lupuli.—Hop*, E.; *Houblon*, Fr.; *Hopfen*, G.

The strobiles of Humulus lupulus, *Lin.* Steph. and Church, Med. Bot., plate 41.

Nat. Ord.—Urticaceæ, Cannabineæ.

Origin.—The hop is distributed over a great portion of the northern temperate zone, and has been introduced into Brazil and Australia. It grows in hedges and thickets, and is indigenous to North America, where it is particularly common in the northern and western regions, and is found in the Sierra Madre range of Colorado at an altitude of 10,000 feet; it is met with also in Middle and Southern Siberia and throughout the greater portion of Europe. In many countries it is extensively cultivated. It is a perennial, producing rough, long, and twining stems, which have the leaves mostly opposite, heart-shaped, and 3 to 5 lobed. The staminate flowers are in short racemes, and the pistillate flowers in densely leafy cone-like spikes upon different plants; these spikes or strobiles are the parts used.

Description.—The strobiles are ovate in shape, 1 to 1½ inch long, and consist of a grayish, hairy, zigzag-shaped somewhat glandular axis, to the angles of which the enlarged leafy bracts and scales are attached; these are obliquely ovate, membranous, parallel-veined below, reticulately veined above, and at the base glandular and surrounding a subglobular akene, which is likewise covered with numerous yellow and shining glands (*lupulin*). Hops are of a yellowish-green color, of an agreeable aromatic odor, and of a bitter, aromatic, slightly astringent taste. When kept for some time, hops acquire a brownish color, and an unpleasant odor from the formation of some valerianic acid; these changes are prevented, or at least retarded, by exposure to sulphurous acid gas, and the color of brown hops is to some extent restored by the same means.

For an account of the culture of hops in the United States, consult papers by W. H. Ramsey in *Amer. Journ. Pharm.*, 1875, p. 241, and E. G. Bissel, 1877, p. 538. In the fiscal year 1875–1876, over 83,000 lbs. of hops were imported into the United States; in the following year only 20,177 lbs.

Constituents.—Besides the principles contained in the yellow glands (see Lupulina), hops contain about 4 per cent. of *tannin*, which, according to R. Wagner, resembles moritannic acid. Bissell (1877), however, found its behavior to mineral acids entirely distinct, and noticed that only a small portion of it is precipitated by gelatin. Bowman (1869) obtained by means of this reagent 3.67 per cent. of tannin. Hops, entirely freed from lupulin, gave to Bissell, with water, a neutral distillate, having an odor distinct from those of hops, and containing mere traces of organic matter; the extract was but slightly bitter. Hops contain 0.8 per cent. of volatile oil (R. Wagner, 1853), between 9 and 18 per cent. of resin (Siewert, 1870), some trimethylamin, and a volatile alkaloid, *lupulina*, having a conia-like odor (Griessmayer, 1874). Sacc (1876) asserted that hops contain a peculiar fermentative principle, which was disproven by Soxhlet and Pasteur (1876). C. G. Wheeler (1865) found hops to contain 1.7 per cent. of nitrogen, and to yield 7 to 10 per cent. of ash, in which potassa, lime, phosphoric acid, and silica predominate.

Off. Prep.—Extractum lupuli, *Br.;* Infusum humuli (lupuli), Tinctura humuli (lupuli), *U. S.*, *Br.*

Physiological Action.—Experiments on animals do not indicate the existence of a narcotic principle in hop, but clearly a sedative one, in that under the use of hop the pulse-rate is diminished. Like other bitters, hop tends to invigorate digestion. Lupulin in moderate doses has the same effect, and in large ones causes abdominal pain and constipation. It certainly calms disordered nervous action, and in this manner favors sleep; but there is no evidence to show that hop, when given to persons in health or free from pain, has distinctly shown narcotic properties. The apparently direct influence of the hop pillow in causing sleep is one which it shares with all odorous flowers, and is due to the essential oil which the strobiles contain.

Medical Uses.—The association in hop of a bitter tonic with a direct sedative of abnormal nervous action, renders it peculiarly fitted to relieve those numerous cases of *dyspepsia* which are due to abuse of the stomach, when it is both irritated and exhausted. Hence at one time it was celebrated in the treatment of atonic *gout*, a disease in which those conditions are prominent.

These qualities also explain its reputation in the treatment of the forms of constitutional derangement which exist in *scrofula* and *rickets*, when anæmia, glandular swellings, cutaneous eruptions, and dropsy, especially of the abdomen, are present. Hop tea is one of the best remedies for *delirium tremens;* it tends to restore its tone to the irritated and exhausted stomach, and directly to allay the characteristic nervous excitement of the attack. In various affections attended with genito-urinary irritation, as *priapism, seminal emissions, nocturnal incontinence of urine*, and *irritable bladder*, its influence is often most salutary. As an external application to relieve the pain of *abscesses, spasms, toothache, colic, bruises*, etc., hop is a most excellent application. It may be incorporated in a poultice, or the strobiles, inclosed in a bag, may be moistened with hot water, vinegar, or alcohol, and applied to the painful part. The infusion of hop is the best preparation for internal use, although so much more bulky than the tincture or the fluid extract of lupulin. A pure and strongly hopped beer contains all the virtues of this agent; but ordinary malt liquors are too often fraudulently adulterated to deserve this praise.

HURA.—SAND BOXTREE.

Sablier, Fr.; *Sandbüchsenbaum*, G.

Nat. Ord.—Euphorbiaceæ.

Description.—The following species have attracted some attention:—

HURA CREPITANS, *Lin.*, indigenous to the West Indies, Central and some portions of South America, and known there as *ajuapar.* It is a straight tree, about 70 feet high, with long petiolate, cordate-ovate and serrate smooth leaves; pendulous ovate staminate catkins, erect dark red or purple pistillate flowers, and depressed globular, twelve to eighteen-celled capsules, which, when ripe, break with some violence, scattering the roundish flattened seeds, which have an agreeable sweetish taste. The tree contains a very acrid milk juice. The leaves, steeped in oil, are used in rheumatic complaints.

HURA BRASILIENSIS, *Willd.*, known in Brazil as *assacou* or *ussacu*, resembles the preceding in appearance and properties, but has oblong catkins. The thick, hard, grayish, inodorous and slightly acrid bark, *casca de assacou*, is employed in South America.

Constituents.—Boussingault and Rivero (1825) ascertained that one of the acrid principles of the milk juice is oily and volatile, the other is crystallizable; the other constituents found were malates, nitrates, etc. Bonastre found in the integuments of the seeds much coloring matter, tannin, and gallic acid, and in the kernel fixed oil, soluble in alcohol, solid fat, albumen and salts.

Medical Action and Uses.—Like several other euphorbiaceæ it is a powerful irritant, and taken internally in large doses occasions violent vomiting and purging. For these reasons, probably, it is used as an anthelmintic. Applied to the skin in decoction it causes irritation and even vesication. In its native country, Brazil, it is much used in the treatment of leprosy, but there is no evidence of its having cured the disease. It is given in the form of a decoction, made by boiling half an ounce of the bark in a pint of water to half a pint. Baths made with a saturated infusion of the bark are also used. It is almost unnecessary to add that neither this medicine nor any other ever cured leprosy, and that the use of a drastic medicine like hura cannot fail to hasten the inevitable progress of the disease.

HYDRANGEA.—HYDRANGEA.

The root of Hydrangea arborescens, *Lin.*

Nat. Ord.—Saxifragaceæ, Hydrangeæ.

Origin and Description.—The wild hydrangea grows near the banks of rivers, preferring rocky places, from Pennsylvania westward to Illinois and southward. It has a pale brown, internally whitish, woody and much branching root, which is of a sweetish and pungent taste. The stem is about 6 feet high, and has a grayish, or on the branches a light reddish-brown bark, which is detached in thin concentric layers, from which circumstance the shrub is known as *seven-barks*. The leaves are opposite, nearly smooth, ovate, pointed, rounded or slightly heart-shaped at the base, and serrate on the margin. The flowers, which appear in July, are in flat cymes, whitish, the marginal ones often sterile and radiant, with 4 or 5 petals, and stamens twice that number. The fruit is a two-celled and two-beaked capsule, containing numerous seeds.

Constituents.—Nothing is known about the principles to which the medicinal properties of the root might be due. Laidley's analysis (1850) merely proved the presence of the common vegetable principles, gum, starch, resin, etc.

Medical Uses.—We are told that hydrangea root was employed by the Cherokee Indians for the relief of calculous complaints, and that when duly administered to persons suffering from urinary concretions in the kidneys and bladder, it provokes their discharge. We are also informed that in overdoses it occasions vertigo, oppression of the chest, etc. In regard to the first statement, it may be remarked that recent confirmation of it is wanting; and in regard to the second, that it would present the singular case of a medicine at once diuretic and narcotic. Further information upon the subject is desirable.

HYDRARGYRI CHLORIDUM CORROSIVUM, *U. S.*—CORROSIVE CHLORIDE OF MERCURY.

Hydrargyri perchloridum, Br.; *Hydrargyrum bichloratum corrosivum*, P. G.; *Hydrargyrum muriaticum corrosivum, Hydrargyrum corrosivum sublimatum, Hydrargyri bichloridum, Sublimatus corrosivus, Sublimatum corrosivum, Mercurius sublimatus corrosivus, Chloruretum (Chloretum) hydrargyricum.—Perchloride of mercury, Corrosive sublimate, Bichloride of mercury*, E.; *Deutochlorure de mercure, Sublimé corrosif, Chlorure mercurique*, Fr.; *Ætzendes Quecksilberchlorid, Ætzender Quecksilbersublimat*, G.

Formula $HgCl_2$. Molecular weight 271.

Preparation.—Take of Mercury twenty-four troyounces; Sulphuric Acid thirty-six troyounces; Chloride of Sodium eighteen troyounces. Boil the mercury with the sulphuric acid, by means of a sand-bath, until a dry white mass is left. Rub this, when cold, with the chloride of sodium in an earthenware mortar; then sublime with a gradually increasing heat. *U. S.*

Take of Sulphate of Mercury twenty ounces; Chloride of Sodium dried sixteen ounces; Black Oxide of Manganese in fine powder one ounce. Reduce the sulphate of mercury and the chloride of sodium each to fine powder, and having mixed them and the oxide of manganese thoroughly by trituration in a mortar, put the mixture into an apparatus adapted for sublimation, and apply sufficient heat to cause vapors of perchloride of mercury to rise into the less heated part of the apparatus which has been arranged for their condensation. *Br.*

Both processes are essentially alike, mercuric chloride being formed by the mutual decomposition of mercuric sulphate (freshly made by the first formula) and sodium chloride: $HgSO_4 + 2NaCl$ yields $HgCl_2 + Na_2SO_4$. By heat, mercuric sulphate is partly decomposed (see Hydrargyri sulphas), and the product of the above process is thereby apt to become contaminated with mercurous chloride or calomel; to prevent such a result, the British Pharmacopœia directs the addition of some binoxide of manganese, which, reacting with some of the sodium salt, generates chlorine sufficient to reconvert any mercurous into mercuric salt. On conducting the vapors into a large chamber, they are condensed in the form of a heavy white crystalline powder.

Properties.—Corrosive sublimate forms colorless prismatic crystals, or, more generally, heavy white crystalline masses. It has the density 5.4, and, when heated, fuses and sublimes without leaving any residue. It has a disagreeable metallic taste, and dissolves in about 2 parts of boiling water and 16 parts of water at the common temperature (Poggiale); also in 3 parts of alcohol and 4 parts of ether. When exposed to the light, its aqueous solution is decomposed with the precipitation of calomel and the liberation of hydrochloric acid; the decomposition is prevented by the presence of free hydrochloric acid or of ammonium chloride. The aqueous solution yields yellow precipitates of mercuric oxide with lime-water (see Lotio hydrargyri flava), or potassa solution, a white precipitate of ammoniated mercury with ammonia, and a white curdy one of silver chloride on the addition of nitrate of silver. Phosphorous and sulphurous acids separate calomel from the solutions; hypophosphorous acid and stannous chloride produce the same change, but when in excess and heated, liberate metallic mercury. The salt is soluble without decomposition in sulphuric, muriatic, or nitric acid, and cystallizes again on cooling.

Tests.—Corrosive sublimate should volatilize without leaving any residue (absence of fixed impurities), and be completely soluble in water or alcohol (absence of calomel). It often contains traces of arsenic, which are probably derived from the sulphuric acid with which the sulphate was prepared; this may be readily detected by mixing the solution with an excess of potassa solution, adding some zinc and heating, the test-tube being covered with filtering paper moistened with a drop of solution of silver nitrate; the appearance of a black spot indicates arsenic. J. G. Smith (1877) found in some samples $\frac{1}{10}$ per cent. of the impurity.

Pharmaceutical Uses.—Corrosive sublimate is employed in making Hydrarg. iodidum rubrum, Hydrarg. oxidum flavum, Hydrargyrum ammoniatum, *U. S.*, *Br.;* Liquor hydrarg. perchlor. and Lotio hydrarg. flava, *Br.*

Physiological Action. *On Animals.*—A solution of one part of this salt in a thousand of water destroys the life of plants, leeches, and fish immersed in it. Introduced into the connective tissue, it is absorbed and occasions the same symptoms and lesions of gastro-intestinal inflammation as if it had been given by the mouth. These symptoms include pain, thirst, vomiting of mucus and blood, and death by convulsion or exhaustion. The gastric lesions vary from slight redness to complete softening; similar ones may be found in the intestine, and especially in the rectum.

On Man.—Poisoning by corrosive sublimate may be produced by its external application as well as by its being taken internally. A solution of it applied to the unbroken skin has repeatedly caused symptoms of poisoning, such as an acrid taste in the mouth, irritation of the œsophagus, vomiting, epigastric pain, constriction of the chest, and a small and irregular pulse. When the skin is not whole, the same and more aggravated effects arise, including those of severe local irritation; and the absorption of mercury is proved by the salivation that ensues, and sometimes by the deposit of mercury upon articles of gold worn next the skin. Poisonous doses of this salt cause constriction and severe burning pain in the fauces, œsophagus, and stomach, with retching and the vomiting of mucus, bile, and blood; the abdomen grows painful under pressure, there is tenesmus, and sometimes bloody stools. There are also intense thirst, a quick, frequent, and small pulse, labored breathing, a cold and clammy skin, and scanty or suppressed urine. Death may occur within a few hours, or may be delayed for several weeks. If recovery takes place, the stomach and bowels remain irritable for a long time. After death from this poison, the stomach is contracted, and the mucous membrane of the œsophagus, stomach, and small intestine occasionally is injected, and sometimes ulcerated. Excessive doses convert the gastric mucous membrane into a soft pulp. Smaller, but not fatal doses present the above symptoms in a milder form and degree, and sometimes, although rarely, cause salivation. Indeed, of all mercurial compounds, this one is least apt to salivate, when taken by the stomach. The presence of a large proportion of table-salt in the food is said to prevent in a great degree the absorption of the bichloride, while a moderate proportion of salt promotes its absorption.

Medical Uses.—Corrosive sublimate has never lost the pre-eminence which it shared with calomel of being the best internal remedy for *syphilis.* In general, it is found not to salivate unless given in doses of at least half a grain twice a day, and even in smaller doses it should be guarded by association with some syrup, bitter extract, or opium, and taken directly after meals. To prevent its decomposition in solution it should be associated with muriate of ammonia, in the proportion of one grain of the bichloride to five grains of the latter salt. To this solution alcohol should be added in the proportion of one part to ten. It is preferable to prescribe as many daily doses of the medicine as the patient takes meals, in order to lessen the chances of gastro-intestinal irritation. In appropriate quantities this preparation is undoubtedly the best in infantile syphilis. About one-ninetieth of a grain should be given in solution three times a day, and generally prescribed in a syrup, or mixed with one when administered. If diarrhœa occurs it should be corrected by diminishing the frequency or the size of the dose, and by adding to it a minute proportion of laudanum. Baths of the bichloride have been used to cure syphilis, and with very great success; they are not apt to salivate, but the irritation of the skin they occasion renders them objectionable. The salt has also been employed hypodermically, but it is not more efficacious in this manner than when given internally, and the inconvenience of repeating the operation, and the severe local effects produced by it, have caused the method to be abandoned.

In various diseases of the *skin*, solutions of corrosive sublimate are useful topical applications; but the strength of the preparation should be carefully regulated, and none should be used if the skin is broken. A solution of fifteen grains of the salt in a pint of water, or, still better, in two fluidounces of dilute alcohol, and fourteen fluidounces of water, forms a very efficacious lotion in many cases of *acne*, especially in the form which affects the nose of certain women at their menstrual periods; in *chloasma;* in the discolorations of the skin which go under the general name of *freckles*; in *prurigo pudendi* as a palliative, and in *pityriasis* usually as a cure. *Malignant pustule* is said to be more efficiently than by any other method treated with corrosive sublimate applied to the raw surface of a crucial incision made through the hardened tissues. *Ozæna*, especially of syphilitic origin, is benefited by the injection into the nostrils of weak solutions of the bichloride, containing one or two grains to the ounce of water, or by a weaker solution applied with the nasal douche. In chronic vaginal *leucorrhœa* a similar application is sometimes useful.

In the subacute and chronic forms of muscular as well as articular *rheumatism*, a very gentle but sustained mercurial lotion will sometimes put an end to the lingering stiffness of the joints. For this purpose very minute doses of the bichloride, in compound syrup of sarsaparilla, will be found appropriate. In chronic rheumatic *arthritis* it is said that baths of the bichloride, and compresses wet with solutions of the salt, have sometimes produced cures of this intractable disease. It is recommended that a full bath should contain from three to eight drachms of the salt. The many possible dangers from the use of so large a quantity of a poisonous liquid should condemn its use, especially when its utility is so questionable.

HYDRARGYRI CHLORIDUM MITE, *U. S.*—MILD CHLORIDE OF MERCURY.

Hydrargyri subchloridum, Br.; *Hydrargyrum chloratum mite*, P. G.; *Hydrargyri chloridum, Hydrargyrum chloratum* (*muriaticum*) *dulce, Mercurius dulcis, Calomelas, Chloruretum* (*Chloretum*) *hydrargyrosum.—Subchloride* (*Protochloride*) *of mercury, Calomel*, E.; *Protochlorure* (*Sous-muriate*) *de mercure, Calomèle*, Fr.; *Quecksilberchlorür, Calomel*, G.

Formula Hg_2Cl_2 (or HgCl). Molecular weight 471 (or 235.5).

Preparation.—Take of Mercury forty-eight troyounces; Sulphuric Acid thirty-six troyounces; Chloride of Sodium eighteen troyounces; Distilled Water a sufficient quantity. Boil, by means of a sand-bath, twenty-four troyounces of the Mercury with the Sulphuric Acid until a dry white mass is left. Rub this, when cold, with the remainder of the mercury, in an earthenware mortar, until they are thoroughly mixed. Then add the chloride of sodium, and, having rubbed it with the other ingredients until globules of mercury cease to be visible, sublime the mixture into a large chamber so that the sublimate may fall in powder. Wash the sublimed matter with boiling distilled water until the washings afford no precipitate with water of ammonia, and dry it. *U. S.*

Take of Sulphate of Mercury ten ounces; Mercury seven ounces; Chloride of Sodium dried five ounces; Boiling Distilled Water a sufficiency. Moisten the sulphate of mercury with some of the water, and rub it and the mercury together until globules are no longer visible; add the chloride of sodium, and thoroughly mix the whole by continued trituration. Sublime by a suitable apparatus into a chamber of such size that the calomel, instead of adhering to its sides as a crystalline crust, shall fall as a fine powder on its floor. Wash this powder with boiling distilled water until the washings cease to be darkened by a drop of sulphide of ammonium. Finally, dry at a heat not exceeding 212° F., and preserve in a jar or bottle impervious to light. *Br.*

Both formulas direct mercuric sulphate, which is freshly prepared in the first part of the first process, to be mixed with the requisite quantity of mercury, to form mercurous sulphate, Hg_2SO_4, and afterwards with chloride of sodium. On heating the mixture reaction takes place between the two salts, resulting in the production of mercurous chloride which sublimes, and sodium sulphate which remains behind; $Hg_2SO_4+2NaCl$ yields $Hg_2Cl_2+Na_2SO_4$ If these vapors are cooled and condensed in a small space, white or yellowish-white crystalline masses would be obtained, which should be finely powdered. To avoid this operation, the Pharmacopœias direct the condensation to be effected in a large chamber, whereby a fine crystalline powder is obtained; it is condensed in a similar form, but still finer and as a still softer powder, by injecting steam into the condensing chamber while the sublimation is in progress. Calomel prepared in this way has been made officinal in the German Pharmacopœia, under the title of *Hydrargyrum chloratum mite vapore paratum*. Water being at the same time condensed, it will hold any corrosive sublimate in solution which may have sublimed with the vapors of calomel. It is for the purpose of removing the same impurity that the ordinarily condensed calomel requires to be washed with water as long as mercuric chloride is dissolved, which is indicated by the filtrate producing a white turbidity with ammonia, or a black one with sulphydrate of ammonium. A current of cold air injected into the condensing chamber will precipitate the calomel vapors as a soft powder in a manner similar to that produced by steam.

Very finely divided calomel is obtained by gradually adding a not too concentrated solution of mercurous nitrate to a solution containing an excess of sodium chloride, digesting the mixture for a short time, and washing the precipitate thoroughly with water. Wöhler (1854) proposed to reduce corrosive sublimate in solution by sulphurous acid, and by warming the mixture. Good results, and nearly the theoretical quantity of calomel, are obtained, according to Sartorius (1855), if the corrosive sublimate has been dissolved in 80 parts, or, according to Stein (1857), in 45 parts of water. Concentrated solutions yield only one-half the mercury as calomel.

Properties.—Calomel is a heavy, fine, and smooth white powder, which, under the microscope, is observed to consist of minute needle-shaped crystals; but when prepared by levigating the crystallized mass, it forms irregular fragments of crystals. Its density is about 7.0, but varies somewhat as prepared by different processes. When heated, it sublimes completely without previous fusion. It is insoluble in water and other simple solvents; but boiled with water it is slowly decomposed into metallic mercury and mercuric chloride. Solutions of the fixed alkalies and alkaline earths decompose it with the formation of soluble chlorides and black mercurous oxide Hg_2O (see Lotio hydrargyri nigra); ammonia water also colors it black, but the resulting compound has the composition NH_2Hg_2Cl. Moist calomel is reduced to the metallic state by many metals either in the cold or on being warmed, soluble chlorides and metallic mercury being formed. Boiling nitric or sulphuric acid dissolves calomel with disengagement of nitric oxide or sulphurous acid vapors and the production of mercuric chloride and nitrate or sulphate. Boiling concentrated hydrochloric acid dissolves mercuric chloride and leaves mercury; in the diluted state and heated in contact with the air, mercuric chloride is slowly dissolved without separation of mercury. Calomel left in contact with solution of ammonium chloride is gradually converted into mercuric chloride, which dissolves; the decomposition occurs more rapidly with a concentrated solution and at a somewhat elevated temperature. Potassium and sodium chlorides have a similar effect, but react more slowly. Chlorine water converts calomel into corrosive sublimate. With potassium iodide a green powder is produced containing mercurous iodide. When triturated with impure sugar, some corrosive sublimate is formed.

Tests.—Calomel should volatilize without leaving any residue (absence of fixed impurities). Heated with potassa solution it should turn black without evolving the odor of ammonia (absence of ammonium compounds). Agitated with warm water or alcohol, the filtrate should not be colored by sulphuretted hydrogen, nor yield a white precipitate with silver nitrate (absence of mercuric chloride). Agitated with diluted acetic acid, the filtrate should not be affected by sulphuretted hydrogen or silver nitrate (absence of ammoniated mercury).

Off. Prep.—Lotio hydrarg. nigra, *Br.;* Pilul. antimonii comp. (hydrarg. subchlor. comp.), *U. S.*, *Br.;* Pilul. catharticæ comp., *U. S.;* Unguent. hydrarg. subchlor., *Br.*

Physiological Action.—The action of calomel does not materially differ from that of uncombined mercury (see Hydrargyrum); it is, however, rather more irritating, and in excessive doses may cause active vomiting and purging. It is a remarkable fact that dogs cannot endure, without experiencing hypercatharsis, a third of the doses of calomel which are administered to the youngest children (Bretonneau). No mercurial is more apt to occasion salivation. This and other effects are by no means constantly proportioned to the dose of the medicine; and since it is certain that it must first undergo solution before it can either act locally or be absorbed, the mode in which these results are brought about has been variously stated and explained. The prevalent hypothesis regarding this point is that the alkaline chlorides convert the calomel into corrosive sublimate, rendering it soluble and absorbable, an opinion which, considering the poisonous properties of that compound, seems irrational.

The cholagogue action ascribed to mercury was an invention of the British physicians in India, who long accepted the doctrine that large doses of calomel diminish the vascularity of the gastro-duodenal mucous membrane, and dissolve the inspissated mucus investing it and obstructing the gall-ducts; and that small doses of the medicine are absorbed, and through the blood promote the secretion of bile. But a careful repetition of their experiments proved that large doses of calomel, as well as small doses, lessen the biliary secretion, and that among purgative medicines mercury in every form is the very one that tends least to augment the discharge of bile. It seems to be agreed that all purgatives, whether they increase the biliary secretion and excretion or not, tend to hurry forward the bile through the intestinal canal, and thereby prevent its reabsorption after combination with the results of gastric digestion. In this manner mercury becomes a cholagogue, not by stimulating the liver to increased secretion, but by carrying off the bile already secreted, preventing its reabsorption, and thereby diminishing whatever evils may arise from an excessive amount of bile in the liver and in the system generally. It has long been believed that a proof of the cholagogue action of calomel is to be found in the darker color of the stools during its administration, which have hence been called "calomel stools," and although one or two experimenters have recently reached the same conclusion, yet the more probable opinion is that the color in question is due to the presence of subsulphide of mercury in the dejections, and that even the natural brown color of the feces is produced, not by the bile, which is all reabsorbed in the small intestine, but by a special excretion of the colon. On the whole, the most probable conclusion upon this subject is expressed in these words: "Calomel is not a cholagogue, but diminishes the secretion of bile."

Medical Uses.—When the cure of *syphilis* was believed to depend upon the profuseness of the mercurial salivation established, calomel was generally employed to produce that effect. But at the present day this action of calomel, along with its tendency to purge, has caused it to be less frequently used than formerly. If prescribed at all, it should be in very small and repeated doses, and the frequency of its administration determined by its effects upon the mouth, the bowels, and the course of the disease. These remarks apply to indurated chancres as well as to secondary symptoms.

Much has been written both for and against the use of calomel in *typhoid fever*, but a careful study of its history seems to show, 1, that it is most useful when given in the forming stage of the disease and in purgative doses; and, 2, that it is peculiarly mischievous in all cases which tend to assume an ataxic or an adynamic type. In other words, it is to be placed, in relation to typhoid fever, in the same category as other purgatives, among which the salines have been proved to be eminently useful in the first period of the disease. It is very probable that calomel, acting as a purgative, assists in removing the poisonous material from the bowel, and possibly tends to neutralize it if it be a ferment; while, owing to its imperfect solubility, the medicine may serve as a protective to the mucous glands of the small intestine. It has been recommended to administer calomel in small and repeated doses, and so as slightly to affect the gums, about the height of the disease, when the tongue grows dry, the abdomen tympanitic, and the mind dull; but if we know anything about the nature of these symptoms, it is that they are signs of increased exhaustion of the nervous system and poisoning of the blood, and, therefore, the very last to be treated by a medicine which tends directly to aggravate those conditions. The period at which these phenomena appear, only to subside again in three or four days, in the natural course of the disease, is the one in which the medicine is supposed to be indicated, and the reason assigned for its use probably results, therefore, from an error of observation.

At one time calomel was held to be a specific in *yellow fever;* according to some if given in large doses, according to others if given in small doses intended to produce its constitutional effects. Experience has condemned both methods as not only useless, but injurious. The same may be said, but not so absolutely, in regard to *remittent fever;* the necessity of "unloading the portal circulation," which purgative doses of calomel were supposed to effect, does not now appear so imperative as it did to the theorists of thirty or forty years ago; but the gastro-duodenal inflammation with the engorged state of the liver are undoubtedly allayed by alvine evacuants, among which calomel is one of the best because it is one of the least irritating, particularly if followed by copious saline draughts in divided portions. The constitutional action of calomel in this disease is no longer sought by judicious physicians.

During the last century, and, indeed, until within a few years, calomel has been used by English and American physicians in all *inflammatory* diseases, with complete faith in its efficacy. Borrowed originally from the treatment of acute hepatitis in hot climates, it was applied in England to a totally different order of diseases, plastic inflammations, and gradually came to be regarded as a specific in most of them. Subsequently this empirical practice was supposed to find a rational justification, when it appeared that mercury diminished the coagulability of the blood by lessening the proportion of its fibrin, and, still later, when it appeared that the medicine directly diminished the proportion of red globules in the blood. The former effect was probably, indeed, only a consequence of the latter. But, although it seemed to be proved that mercury thus restricted inflammatory action and its consequences, it was not proved that their restriction by this means was necessary to cure the disease, and it was even rendered probable that the antiphlogistic use of calomel involved more danger than advantages. Extensive observation has now demonstrated that, with one or two possible exceptions, inflammatory affections may be cured quite as rapidly, and much more safely and agreeably, without mercury than with it, while the dangers involved in the antiphlogistic use of the medicine are so serious as to condemn it whenever a safer remedy can be substituted for it.

Of acute inflammations, for whose treatment calomel has been long supposed essential, may be mentioned *pericarditis*, *endocarditis*, *pleurisy*, *pneumonia*, *peritonitis*, *meningitis*, and *hepatitis*. It is now apparently determined that none of these diseases require calomel for their cure, and that most of them are aggravated by it. In regard to peritonitis, it may be added that as the disease is never idiopathic, at least in adults, and never primary unless traumatic, pathology confirms what clinical observation demonstrates, that mercury is unsuited to its cure. Acute hepatitis is not now, as formerly, indiscriminately treated by calomel in tropical climates, where alone it is frequently observed. The use of mercurial, as of other purgatives, appears to be beneficial in the early stage of the disease, but not through its specific operation. There are good grounds for suspecting that in hot climates its repeated administration in divided doses leads to the formation of abscess of the liver. Meningitis, like peritonitis, is always a secondary disease when not traumatic; depending upon a specific poison in epidemic cerebro-spinal meningitis, upon the rheumatic poison in another class of cases, upon tubercle in a third, etc. In no form of meningitis is calomel of any avail unless it may be in certain exceptional cases of the tubercular variety; although it must be confessed that diagnostic difficulties obscure the subject, still, in the present state of our knowledge, mercury stands next to iodine in the promise of doing good. Calomel is worse than useless in acute articular *rheumatism;* it neither mitigates the disease nor prevents its complications. In certain cases of subacute and chronic rheumatism involving the ligaments of the joints, rendering the latter stiff and painful on motion, a course of very small doses of calomel will sometimes act beneficially. But more advantage may be derived from iodide of potassium. In *metritis*, both acute and chronic, calomel and opium are generally administered with supposed advantage. In diseases of the *kidney*, whether acute or chronic, mercury is a mischievous medicine. *Iritis*, although it may, in its simple form, recover without mercury, is more readily cured by calomel and opium internally, and mercurial ointment with extract of belladonna or instillation of atropia, topically. Syphilitic iritis should always be treated by the internal use of calomel, if not by mercurial inunctions.

In *jaundice* depending upon engorgement of the liver or upon obstruction of its ducts with thick bile, saline purgatives are the appropriate remedies, but the English custom of first administering calomel or blue pill prevails in this country. It is very doubtful whether the mercurial renders the purgative treatment more efficient. It can do no harm as an occasional remedy, but is very mischievous if habitually taken.

Among mucous inflammations, *pseudomembranous laryngitis*, or true croup (and not diphtheria, which is a totally different affection), is treated by calomel internally, and by mercurial inunctions, in the belief that, under its operation, exudation-matter will form less densely and adhere less tenaciously, and hence be rejected by coughing or by vomiting more readily. The question of their efficacy is difficult to solve, for the cases of the disease differ widely among themselves in the thickness and tenaciousness of the membrane, and in the extent of its deposit. But in a disease with such fatal tendencies even a doubtful remedy should not be rejected. In *syphilitic laryngitis*, which is generally ulcerative, calomel, or mercury in some form, is indispensable. In acute *dysentery* calomel has been used as a purgative, and in small or so-called alterative doses. There appears to be no doubt that in the sthenic form of the disease purgative doses of calomel, if given in the forming stage, will modify the course of the disease just as salines, rhubarb, and ipecacuanha will. There is no reason to attach any special importance to calomel as such. Its virtue resides chiefly in its mild evacuant and substitutive action. In this disease calomel, in small or fractional doses, is most useful when associated with ipecacuanha, and least so when combined with opium. The advantage of the latter treatment consists mainly in its negative virtue of protecting the patient from perturbative measures. It is most suitable when the acute stage has begun to decline, and after a judicious evacuant treatment has mitigated the severity of the attack. A similar remark is, perhaps, justifiable in regard to the calomel treatment of epidemic *cholera*. The huge doses of the drug which were originally used by the British East India surgeons have long ago been condemned, as well as the other elements of their crude therapeutics. If calomel has shown any special virtues in epidemic cholera it has only been when it was administered in doses of one or two grains every five or ten minutes, with one or two drops of laudanum in each of the first few doses. Knowing, as we do, the utter loss by the stomach of its absorbing function in this disease, the method in question really amounts to a negative treatment, and this, it is pretty well settled, is more efficient than any of the active methods which have prevailed. The hostile influence of mercury upon the lower forms of animal life explains the propriety of using calomel purges in some cases of *lumbricoid worms*. But the possibility of its poisonous action on the system renders it less eligible for this purpose than other direct vermicides.

In an ointment (calomel ʒj, lard ℥j) calomel is sometimes used locally in the treatment of limited *scaly eruptions;* and in powder it has been used to destroy *maggots* infesting wounds in hot weather. In the latter form, also, it has been applied to *ulcers of the cornea*, but is not strongly to be recommended for this purpose.

Administration.—Calomel is most conveniently given mixed with a little syrup, or inclosed in wafers. As a purgative *dose* from five to twenty grains may be administered. Children require larger doses, in proportion to their age, than adults. To produce the constitutional action, of which the first sign is usually a metallic taste in the mouth or soreness of the gums, one or two grain may be given three times a day, with an eighth of a grain of opium; but still smaller doses, more frequently repeated, as a tenth or the twelfth of a grain every hour, will affect the system more promptly.

HYDRARGYRI CYANIDUM, *U. S.*—CYANIDE OF MERCURY.

Hydrargyrum cyanatum (borussicum), Mercurius cyanatus s. borussicus, Cyanuretum hydrargyricum.—Cyanuret of mercury, E.; *Cyanure (Bicyanure, Prussiate) de mercure*, Fr.; *Cyanquecksilber, Quecksilber-Cyanid*, G.

Formula $HgCy_2$ or $Hg(CN)_2$. Molecular weight 252.

Preparation.—Take of Ferrocyanide of Potassium five troyounces; Sulphuric Acid four troyounces and one hundred and twenty grains; Red Oxide of Mercury in fine powder, Water, each a sufficient quantity. Dissolve the ferrocyanide of potassium in twenty fluidounces of water, and add the solution to the sulphuric acid, previously diluted with ten fluidounces of water, and contained in a glass retort. Distil the mixture nearly to dryness into a receiver, containing ten fluidounces of water and three troyounces of red oxide of mercury. Set aside two fluidounces of the distilled liquid, and to the remainder add, with agitation, sufficient red oxide to destroy the odor of hydrocyanic acid. Then filter the solution, and, having added the reserved liquid, evaporate the whole in a dark place, in order that crystals may form. Lastly, dry the crystals, and keep them in a well-stopped bottle, protected from the light. *U. S.*

Hydrocyanic acid is prepared as the first step by acting upon potassium ferrocyanide with sulphuric acid. (See Acid. hydrocyanicum, page 49.) On agitating it with mercuric oxide, a combination is effected resulting in the production of mercuric cyanide and water; $2HCy+HgO$ yields $HgCy_2+H_2O$. Should an excess of mercuric oxide be present, it will combine with the cyanide to mercuric oxycyanide, $HgO.HgCy_2$, which is converted into cyanide by the addition of the reserved portion of hydrocyanic acid; an excess of the latter does not change the nature of the product.

This is not the only process, but the most convenient one, by which mercuric cyanide may be obtained. On boiling pure ferrocyanide of iron with mercuric oxide, mercuric cyanide enters into solution; and on boiling potassium ferrocyanide with a proper quantity of mercuric sulphate, a complex reaction will take place, resulting finally in the production of metallic mercury and of a solution containing mercuric cyanide, potassium sulphate, and ferric sulphate, to be separated by crystallization; $7HgSO_4+2K_4FeCy_6=Hg+6HgCy_2+4K_2SO_4+Fe_23SO_4$.

Properties.—Mercuric cyanide is in colorless or white quadrangular prisms, which are soluble in eight parts of water and about twenty parts of alcohol, but quite sparingly soluble in absolute alcohol. The aqueous solution is not decomposed by nitric or dilute sulphuric acid, but hydrochloric acid liberates hydrocyanic acid, recognizable by its odor, and mercuric chloride remains in solution. The aqueous solution is not precipitated by alkalies or nitrate of silver; but yields a black precipitate with sulphuretted hydrogen. The salt has a bitter metallic taste, is blackened by exposure to the light, and when carefully heated is decomposed into mercury and cyanogen, which is inflammable, burning with a purplish flame. When rapidly heated, black paracyanogen remains behind, and in the presence of moisture carbonic acid and ammonia are evolved besides hydrocyanic acid.

Tests.—Mercuric oxycyanide, if present, is sparingly soluble in cold water, and the solution imparts a brown color to turmeric paper.

Medical Action and Uses.—Cyanide of mercury is a violent irritant poison, producing also extreme prostration and local cyanosis, and death by exhaustion. It has been used in the treatment of syphilis, but no sufficient reason appears for retaining so dangerous a preparation among officinal medicines. Twenty grains of it caused death in ten days, and two grains a severe illness which lasted for three weeks.

HYDRARGYRI IODIDUM RUBRUM, *U. S.*, *Br.*—RED IODIDE OF MERCURY.

Hydrargyrum biiodatum rubrum, P. G.; *Deutoioduretum* (*Biniodidum*) *hydrargyri*, *Mercurius iodatus ruber*, *Ioduretum hydrargyricum.*—*Biniodide of mercury*, E.; *Deuto-iodure* (*Bi-iodure*) *de mercure*, *Iodure mercurique*, Fr.; *Rothes Jodquecksilber*, *Quecksilberjodid*, G.

Formula HgI_2. Molecular weight 454.

Preparation.—Take of Corrosive Chloride of Mercury a troyounce; Iodide of Potassium a troyounce and one hundred and twenty grains; Distilled Water a sufficient quantity. Dissolve the corrosive chloride of mercury in a pint and a half, and the iodide of potassium in half a pint of distilled water, and mix the solutions. Collect the precipitate upon a filter, and, having washed it with distilled water, dry it with a gentle heat, and keep it in a well-stopped bottle. *U. S.*

Take of Perchloride of Mercury four ounces; Iodide of Potassium five ounces; Boiling Distilled Water four pints. Dissolve the perchloride of mercury in three pints, and the iodide of potassium in the remainder of the water, and mix the two solutions. When the temperature of the mixture has fallen to that of the atmosphere, decant the supernatant liquor from the precipitate, and, having collected the latter on a filter, wash it twice with cold distilled water, and dry it at a temperature not exceeding 212° F. *Br.*

Mercuric chloride and potassium iodide, when mixed in the proportion of the weights of one molecule of the former to two of the latter salt, decompose each other into mercuric iodide, which precipitates, and potassium chloride, which remains in solution; $HgCl_2 + 2KI$ yields $HgI_2 + 2KCl$. Both Pharmacopœias use the two salts in the proportion of 4 to 5, which is a slight excess of the potassium salt over the theoretical quantity, but is generally necessary in practice, owing to the small percentage of impurities always present in commercial iodide of potassium. By mixing the two solutions cold, the new compound is separated in the form of powder, but when the hot solutions are mixed and slowly cooled, beautiful crystals are obtained. In either case the yield should not be less than 50 per cent. over the weight of the corrosive sublimate used.

Properties.—Mercuric iodide is a scarlet-red powder or is in brilliant crystals; on being heated it turns yellow, fuses near 240° C. (464° F.) to an amber-colored liquid, and sublimes to bright yellow tabular crystals, which, after cooling, are again converted into the prismatic or octahedral red crystals. The salt is very sparingly soluble in cold or hot water, little so in ether, and freely in hot alcohol, from which it crystallizes on cooling. The solutions are colorless, and are partly decomposed by potassa solution, a portion of the mercury being deposited as mercuric oxide; the remainder forming a soluble iodide of potassium and mercury. When a hot solution of potassium iodide is saturated with mercuric iodide, and then allowed to cool, one-third of the latter salt crystallizes on cooling; the remainder is obtained, on further concentration, as yellow prisms, which are soluble in alcohol and ether, but are partly decomposed by water. The crystals are *mercuric potassium iodide*, $2(KI.HgI_2)3H_2O$, more generally known as *iodohydrargyrate of potassium*, and are likewise formed on adding mercuric chloride to an excess of potassium iodide.

Impurities, if present, are readily detected by the residue left on subliming the salt (red oxide of lead and other non-volatile compounds), and on dissolving it in hot alcohol (vermilion, etc.).

Pharmaceutical Uses.—The observation of Nessler (1856) of the effect of ammonia upon such solutions, has resulted in the discovery of a very delicate reagent for minute quantities of ammonia or ammonia salts, known as the

NESSLER REAGENT.—It is made by dissolving 50 grams of potassium iodide in a little boiling distilled water, and adding to it, carefully, sufficient boiling hot concentrated solution of mercuric chloride until the red precipitate formed is no longer redissolved on agitation; the liquid is decanted and filtered, and the filtrate mixed with 200 grams of potassa dissolved in a small quantity of water; when cold the mixture is diluted to the measure of one liter by the addition of distilled water. It will be observed that this is a solution of mercuric-potassium iodide in caustic potassa. On the addition of ammonium salt this is decomposed by the potassa, ammonia is liberated and reacts now with the double iodide and another portion of the potassa, resulting in the formation of brown insoluble dimercur-ammonium (NHg_2) iodide, potassium iodide, and water, as will be seen from the equation $NH_3 + 2(KI.HgI_2) + 3KHO = NHg_2I + 5KI + 3H_2O$. If the ammonia is present in minute quantity, the color is best observed by looking through the column of the liquid contained in a tall test-tube and placed on white paper.

Winckler (1830), Von Planta (1846), and Groves (1858), observed the behavior of solutions of the double iodide upon solutions of vegetable alkaloids, which led F. F. Mayer (1862) to the adoption of a tenth normal solution, now known as

MAYER'S SOLUTION.—It is prepared by dissolving 13.546 grams of mercuric chloride and 49.8 potassium iodide in sufficient distilled water to obtain one liter of liquid. The test is applied in acidulated aqueous solutions, since ammonia would also be precipitated if an alkaline liquid was used. One cubic centimeter of this test liquid precipitates of

Aconitia	0.0267 grams.	Conia	0.00416 grams.	Quinia	0.0108 grams.
Atropia	0.0145 “	Morphia	0.020 “	Quinidia	0.0120 “
Brucia	0.0233 “	Narcotina	0.0213 “	Strychnia	0.0167 “
Cinchonia	0.0102 “	Nicotina	0.00405 “	Veratria	0.0269 “

The end of the precipitation is determined by filtering a few drops of the liquid tested upon a watch-crystal, and by placing a small drop of the test solution alongside, allowing the two to run together. For colorless solutions, which are free from chlorides, etc., an excess of the test liquid may be used, and the excess determined in the filtrate by a standard solution of silver nitrate.

Off. Prep.—Liq. arsen. et hydrarg. iodidi, *U. S.;* Unguent. hydrarg. iodidi rubri, *Br.*

Medical Action and Uses.—Biniodide of mercury is a powerful irritant poison. Two grains of it taken with a drachm of iodide of potassium caused violent gastric pain, coma, stertor, opisthotonos, and convulsion. As an internal remedy it is superfluous, and dangerous unless very cautiously used. It may, however, be given in constitutional *syphilis* in a solution of iodide of potassium, and in the dose of one-sixteenth of a grain, cautiously increased. As a caustic, it has been applied to the treatment of *lupus*, but is inferior to other substances used for this purpose.

HYDRARGYRI IODIDUM VIRIDE, *U. S.*, *Br.*—GREEN IODIDE OF MERCURY.

Hydrargyrum iodatum flavum, P. G.; *Hydrargyrum iodatum, Hydrargyri iodidum (vel proto-ioduretum), Ioduretum hydrargyrosum.—Yellow iodide of mercury, Mercurous iodide*, E.; *Proto-iodure de mercure, Iodure mercureux*, Fr.; *Quecksilberjodür, Gelbes Jodquecksilber*, G.

Formula Hg_2I_2 (or HgI). Molecular weight 654 (or 327).

Preparation.—Take of Mercury a troyounce; Iodine three hundred grains; Stronger Alcohol a sufficient quantity. Mix the mercury and iodine in a mortar, and, having added half a fluidounce of Stronger Alcohol, triturate the mixture until the ingredients are thoroughly incorporated. Stir the mixture occasionally, and, at the end of two hours, triturate again, with considerable pressure, until it is nearly dry. Then rub it up with stronger alcohol, gradually added, until it is reduced to a uniform, thin paste; and, having transferred this to a filter, wash it with stronger alcohol until the washings cease to produce a permanent cloudiness when dropped into a large quantity of water. Lastly, dry the iodide in the dark with a gentle heat, and keep it in a well-stopped bottle, protected from the light. *U. S.*

Take of Mercury one ounce; Iodine two hundred and seventy-eight grains; Rectified Spirit a sufficiency. Rub the iodine and mercury in a porcelain mortar, occasionally moistening the mixture with a few drops of the spirit, and continuing the trituration until metallic globules are no longer visible, and the whole assumes a green color. The product thus obtained should be dried in a dark room on filtering paper, by simple exposure to the air, and preserved in an opaque bottle. *Br.*

Mercury and iodine are contained in mercurous iodide very nearly in the proportion 8 : 5, as directed by the United States and German Pharmacopœias; this gives a slight excess of mercury, amounting to less than 2.5 per cent. of the weight of the iodide. The French Codex directs the proportion 5 : 3, insuring a still greater excess of mercury. The proportion used by the British Pharmacopœia is that of the atomic weights of the two elements. On bringing iodine and mercury together, they unite, forming mercurous or mercuric iodide, according to the proportions employed. It appears, however, that a portion of mercuric iodide is always formed, and being poisonous, requires to be removed or reduced to mercurous iodide by long trituration. The former is the course adopted by the Pharmacopœias, the British excepted, the removal being accomplished by washing the product with alcohol. Le Canu (1877) states the washing to be unnecessary if the mercury is first finely divided by trituration with a little alcohol before the iodine is added in small portions. But even in this case we would prefer the subsequent employment of alcohol to insure the absence of the red iodide.

It has been repeatedly proposed to prepare mercurous iodide by double decomposition of calomel or other mercurous salt with iodide of potassium; the results, however, are never satisfactory, since, by the action of the potassium salt, some red iodide is formed and metallic mercury liberated. (See a paper in *Amer. Journ. Pharm.*, 1857, p. 11.)

Properties and Tests.—Mercurous iodide which has not been washed with alcohol is dark green; but having been freed from the red iodide by either hot or cold alcohol it is greenish-yellow. On exposure to the light red iodide is formed, it turns dark green and finally black, the decomposition being accelerated by moisture. When heated it turns red-brown, and finally sublimes, yielding mercury and red crystals of mercuroso-mercuric iodide $Hg_2I_2.2HgI_2$, which become yellow on cooling. Mercurous iodide is almost insoluble in water and entirely insoluble in alcohol and ether; when treated with alcohol, the filtrate on being dropped into water should produce only a very faint cloudiness, and on evaporation should leave only a minute trace of red iodide. Fixed impurities, if present, remain behind if a portion is heated to redness in a porcelain crucible.

Medical Action and Uses.—Green iodide or protiodide of mercury is chiefly used in the treatment of constitutional *syphilis*, and is preferred above other preparations by several eminent syphilographers. It should be given in doses of from three-quarters of a grain to one grain three times a day, and gradually increased until these doses are trebled, or more, provided that neither salivation nor diarrhœa occurs. It is less apt than calomel to produce these effects. The following formula is much employed: ℞. Protiodide of mercury, Extract of lettuce, each 45 grains; Extract of opium, 15 grains; Confection of roses, 90 grains. Mix, and divide into sixty pills. One, two, or three to be taken daily.

HYDRARGYRI OXIDUM FLAVUM, *U. S.*, *Br. Add.*—YELLOW OXIDE OF MERCURY.

Hydrargyrum oxydatum via humida paratum, P. G.; *Hydrargyrum oxydatum præcipitatum (vel flavum).—Precipitated oxide of mercury*, E.; *Oxyde de mercure jaune (précipité)*, Fr.; *Präcipitirtes (Gelbes) Quecksilber-Oxyd*, G.

Formula HgO. Molecular weight 216.

Preparation.—Take of Corrosive Chloride of Mercury four troyounces; Solution of Potassa seventeen troyounces; Distilled Water a sufficient quantity. Dissolve the corrosive chloride of mercury in five pints of distilled water, and mix with the solution of potassa; after the precipitate has subsided, pour off the supernatant liquid, and wash with distilled water until the washings cease to be affected by a solution of nitrate of silver. Then dry the precipitate on bibulous paper, in a dark place, and preserve it in bottles, protected from the light. *U. S.*

Take of Perchloride of Mercury four ounces; Solution of Soda two pints; Distilled Water a sufficiency. Dissolve the perchloride of mercury in four pints of distilled water, aiding the solution by the application of heat, and add this to the solution of soda. Stir them together; allow the yellow precipitate to subside; remove the supernatant liquor by decantation; thoroughly wash the precipitated oxide on a calico filter with distilled water, and finally dry it by the heat of a water-bath. *Br.*

On mixing solutions of mercuric chloride and potassa or soda, an alkaline chloride, water, and mercuric oxide are formed, the latter being precipitated; $HgCl_2 + 2HKO$ yields $2KCl + H_2O + HgO$. The alkali must be in excess, lest some mercuric oxychloride would be precipitated with the oxide, and it is advisable to pour the mercuric solution into the alkali. The German Pharmacopœia directs boiling solution of soda.

Properties and Tests.—It is a heavy, smooth, yellow or reddish-yellow powder, which on exposure to light becomes dark in consequence of partial reduction to mercurous oxide, and when heated assumes a red color. When mixed with a solution of oxalic acid, it forms white mercuric oxalate (difference from red oxide). Heated with an alcoholic solution of mercuric chloride it speedily turns black from the formation of an oxychloride; red mercuric oxide slowly undergoes a similar change (Roucher). It should be completely volatilized by heat, or leave only a very minute residue.

Off. Prep.—Unguent. hydrarg. oxidi flavi, *U. S.*

Medical Uses.—This preparation is only used as an external remedy to stimulate indolent *ulcers*, especially of venereal origin, and as an application to granular and ulcerated conditions of the *eyes*. It is applied, chiefly, in an ointment, which is officinal.

HYDRARGYRI OXIDUM RUBRUM, *U. S.*, *Br.*—RED OXIDE OF MERCURY.

Hydrargyrum oxydatum rubrum, P. G.; *Hydrargyri nitrico-oxidum*, *Mercurius corrosivus* (*præcipitatus*) *ruber*, *Oxydum hydrargyricum.*—*Peroxide of mercury*, *Red precipitate*, *Mercuric oxide*, E.; *Deuto-oxyde* (*Peroxyde*) *de mercure*, *Oxyde mercurique*, *Précipité rouge*, *Poudre de Jean de Vigo*, Fr.; *Rothes Quecksilberoxyd*, *Rother Präcipitat* (*Quecksilber-Präcipitat*), G.

Formula HgO. Molecular weight 216.

Preparation.—Take of Mercury thirty-six troyounces; Nitric Acid twenty-four troyounces; Water two pints. Dissolve the mercury, with the aid of a gentle heat, in the acid and water previously mixed, and evaporate to dryness. Rub the dry mass into powder, and heat it in a very shallow vessel until red vapors cease to arise. *U. S.*

Take of Mercury by weight eight ounces; Nitric Acid four and a half fluidounces; Water two fluidounces. Dissolve half the mercury in the nitric acid diluted with the water, evaporate the solution to dryness, and with the dry salt thus obtained, triturate the remainder of the mercury until the two are uniformly blended together. Heat the mixture in a porcelain dish, with repeated stirring, until acid vapors cease to be evolved, and, when cold, inclose the product in a bottle. *Br.*

In both processes nitrate of mercury is formed as the first step; this is directly decomposed by heat, or, as directed by the second formula, previously mixed with an additional quantity of mercury, which during the subsequent heating is oxidized at the expense of the nitrate. In both cases the color changes to yellow and then to red, red fumes of nitric peroxide being given off. Occasionally a minute quantity of nitrate remains undecomposed. The decomposition by the second formula is as follows: $2(Hg2NO_3) + Hg_2 = 4HgO + 2N_2O_4$.

Properties and Tests.—When made on a small scale it is a finely granular powder of a yellowish-red color, without lustre; but made in larger quantities it is obtained in the form of bright brownish-red shining crystalline scales, which on trituration yield a fine orange-red powder. By exposure to light it becomes superficially black, but much more slowly than the yellow oxide. When heated, its color is changed to dark-red, brown, and black, the original color reappearing on cooling; but when heated to a little beyond the boiling point of mercury, it is decomposed into metal and oxygen. When thus treated red nitrous vapors should not be given off (absence of nitrate), and no residue should be left (absence of non-volatile impurities). It dissolves completely in nitric acid; a red-colored residue would indicate the presence of brick-dust or of vermilion, the latter being volatilizable by heat; a brown residue (of puce-colored oxide of lead) would prove an adulteration with red lead, and the nitric acid solution would contain lead recognizable by the white precipitate appearing on the addition of a little sulphuric acid.

The preparation formerly officinal in various Pharmacopœias as *Mercurius præcipitatus per se* or *Mercurius calcinatus* was red oxide of mercury in the form of crystalline scales, which were obtained by keeping metallic mercury in a loosely-covered flask at a temperature near its boiling point. The process required several weeks for its completion.

Pharmaceutical Uses.—Red oxide of mercury is used in preparing Hydrarg. cyanidum and Liq. hydrarg. nitratis, *U. S.* It is a constituent of Unguent. hydrarg. oxidi rubri, *U. S.*, *Br.*

Medical Action and Uses.—Red precipitate is a powerful irritant, and taken internally may act as a corrosive poison. Its application to ulcers, wounds, etc., has been frequently followed by its constitutional operation, including salivation. The last-named effect is said to be unusual when the medicine is administered internally, as it sometimes has been in the treatment of *syphilis*, in the *dose* of one-tenth of a grain twice a day and gradually increased. Externally it is generally used in the form of an ointment; but sometimes it is also applied as a fine powder mixed with sugar to indolent syphilitic ulcers, condylomata, etc., and even to granular eyelids and opacities of the cornea.

HYDRARGYRI PERCHLORIDUM, *Br.* See HYDRARGYRI CHLORIDUM CORROSIVUM.

HYDRARGYRI SUBCHLORIDUM, *Br.* See HYDRARGYRI CHLORIDUM MITE.

HYDRARGYRI SULPHAS, *Br.*—SULPHATE OF MERCURY.

Hydrargyrum sulphuricum, Mercurius vitriolatus, Sulfas mercuricus.—Persulphate of mercury, Mercuric sulphate, E.; *Deuto-sulfate (Persulfate) de mercure, Sulfate mercurique,* Fr.; *Schwefelsaures Quecksilberoxyd,* G.

Formula $HgSO_4$. Molecular weight 296.

Preparation.—Take of Mercury by weight twenty ounces; Sulphuric Acid twelve fluidounces. Heat the mercury with the sulphuric acid in a porcelain vessel, stirring constantly until the metal disappears, then continue the heat until a dry white salt remains. *Br.*

Mercury does not dissolve in cold sulphuric acid; but on heating the mixture sulphurous acid and watery vapors are disengaged, any excess of sulphuric acid is driven off, and the residue consists of mercuric sulphate: $Hg_2 + 4H_2SO_4$ yields $2SO_2 + 4H_2O + 2HgSO_4$.

Properties and Tests.—Mercuric sulphate is a heavy white crystalline powder which, on being mixed with a small quantity of water, is at first colored yellow, but after some time is converted into colorless shining prisms of the hydrated salt. A larger quantity of water decomposes it permanently into yellow basic sulphate. When heated to redness, it is decomposed and entirely volatilized; any non-volatile residue left would indicate impurities. The salt is partly decomposed by heat, mercurous sulphate and mercury being sublimed, besides undecomposed mercuric sulphate.

Pharmaceutical Uses.—It is employed for the preparation of turpeth mineral, corrosive sublimate, and calomel.

It is not used in medicine.

HYDRARGYRI SULPHAS FLAVA, *U. S.*—YELLOW SULPHATE OF MERCURY.

Hydrargyri subsulphas, Hydrargyrum sulphuricum flavum, Mercurius emeticus flavus, Sulphas hydrargyricus flavus, Turpethum minerale.—Subsulphate of mercury, Turpeth mineral, E.; *Sulfate trimercurique, Sulfate jaune de mercure, Turbith minéral,* Fr.; *Basisch swefelsaures Quecksilberoxyd, Mineralischer Turpeth,* G.

Formula $2HgO.HgSO_4$. Molecular weight 728.

Preparation.—Take of Mercury four troyounces; Sulphuric Acid six troyounces. Mix them in a glass vessel, and boil, by means of a sand-bath, until a dry white mass remains. Rub this into powder, and throw it into boiling water. Pour off the supernatant liquid, wash the yellow precipitate repeatedly with hot water and dry it. *U. S.*

In the first part of the process mercuric sulphate is formed, which, by the subsequent addition of water, is converted into basic or *oxy-mercuric sulphate*, while an acid sulphate remains in solution. The result varies somewhat, depending upon the amount and the temperature of the water. Using three times a pint of boiling water for the above quantities, the yield will be about 75 per cent. of the weight of the dry mercuric sulphate used.

Properties and Tests.—Yellow sulphate (or oxysulphate) of mercury is a heavy bright lemon-yellow powder which, on heating, becomes red, and yellow again on cooling; by a higher heat, it is completely volatilized. It requires 2000 parts of cold and 600 parts of boiling water for solution (Fourcroy). It is decomposed by potassa solution, yellow mercuric oxide being formed, and dissolves completely in hydrochloric acid, the solution, according to Mohr, containing corrosive sublimate and free sulphuric acid; it should answer to all the tests for mercuric oxide and sulphate.

Medical Action and Uses.—Turpeth mineral is a powerful irritant, and in sufficient doses may act as a corrosive poison, causing active corrosion of the fauces, œsophagus, and stomach, and even sloughing of the first-named parts, as well as salivation. Several fatal cases of its use are recorded. In spite of these grave effects, turpeth mineral has been used as an emetic in "croup," by which was probably meant spasmodic laryngitis. The employment of so dangerous a remedy in a disease which involves no danger to life is inexcusable. The emetic action of this preparation is the first stage of its poisonous operation. The *dose* fitted to produce that effect is from two to three grains for a child. Owing to its tendency to salivate, it should not be employed as an errhine.

HYDRARGYRI SULPHURETUM RUBRUM, *U. S.*—RED SULPHURET OF MERCURY.

Hydrargyrum sulfuratum rubrum, P. G.; *Cinnabaris, Sulfuretum hydrargyricum.—Red sulphide of mercury, Cinnabar, Vermilion*, E.; *Sulfure rouge de mercure, Cinnabre*, Fr.; *Rothes Schefelquecksilber, Zinnober*, G.

Formula HgS. Molecular weight 232.

Preparation.—Take of Mercury forty troyounces; Sublimed Sulphur eight troyounces. To the sulphur, previously melted, gradually add the mercury, with constant stirring, and continue the heat until the mass begins to swell. Then remove the vessel from the fire and cover it closely to prevent the contents from inflaming. When the mass is cold, rub it into powder and sublime. *U. S.*

The preparation of vermilion is carried on in large establishments, and will hardly ever be attempted by the pharmacist, except as an experiment. It may be obtained in the dry or humid way. The officinal process belongs to the former class, but a large excess of sulphur is directed, 6½ troyounces being sufficient for the quantity of mercury; the excess is volatilized before the cinnabar is condensed. If the black mass obtained in the first part of the above process is digested with solution of potassa and some potassium sulphuret, at a temperature of about 45° C. (113° F.), it will be gradually converted into vermilion.

Properties and Tests.—Vermilion is seen in commerce in the form of a bright scarlet-red powder which, on being heated, becomes brown, then black, and finally volatilizes, and assumes its red color again on cooling. Heated in contact with the air, it burns with a blue flame, emitting the odor of sulphurous acid. Nitro-muriatic acid dissolves it with the separation of sulphur and the production of sulphuric acid and mercuric chloride. Its complete volatility by heat insures the absence of red lead and basic lead chromate (American vermilion); and when it is treated with warm solution of potassa, the colorless solution, on being acidulated, would yield a yellow or orange precipitate if sulphides of arsenic or antimony were present.

HYDRARGYRI SULPHURETUM NIGRUM, s. *Æthiops mineralis.*—This preparation has been very properly discarded by the United States and British Pharmacopœias, but is still employed on the continent of Europe. It is made by triturating equal weights of mercury and sulphur, until all metallic globules have disappeared. It forms a fine black and heavy powder which, when viewed with a lens, does not show any globules of uncombined mercury. When heated upon a plate, it takes fire and burns with a blue flame, without leaving any residue; heated in a test-tube, it yields a red sublimate of vermilion. When digested with hydrochloric acid, the acid liquid does not yield a white precipitate on being diluted with water (absence of antimony). Ethiops mineral is a mixture of black amorphous sulphide of mercury, HgS, with a large excess of sulphur.

Medical Action and Uses.—This, like other metallic sulphurets, is less irritating than the sulphates of the same metal. Indeed, there is much reason for believing that in its natural state it has no action at all. It is seldom used, and then only by fumigation, the powdered cinnabar being strewn upon hot coals; the sulphuret is decomposed, and the fumes contain metallic mercury and sulphurous acid. The irritating action of the latter renders the method objectionable. As occasionally used, the patient is inclosed in a wooden box with an aperture through which his head passes, so that he is not obliged to inhale the irritating fumes. This method is said to be a very efficient one, although not without the risk of salivating, causing congestion of the brain, etc.

HYDRARGYRUM, *U. S.*, *Br.*—MERCURY.

Hydrargyrum, Mercurius vivus, Argentum vivum.—*Quicksilver*, E.; *Mercure, Vif-argent*, Fr.; *Quecksilber*, G.

Symbol Hg. Atomicity bivalent. Atomic weight 200.

Origin.—Mercury is principally obtained from New Almaden in California, from Peru, China, Idria in Austria, and Almaden in Spain. It is found to some extent in the metallic state in the form of minute or large globules; but the principal ore for extracting it is *cinnabar.*

Preparation.—Most of the mercury is obtained by roasting the ore in a kiln. It is placed upon an arch of brick-work containing several openings, through which the flames pass, whereby the sulphur of the ore is ignited and burns, air being admitted at the same time; the heat thus produced volatilizes the mercury, the vapors of which, mingled with the smoke and sulphurous acid gas, are passed through a series of condensing chambers, where the metal is condensed, the incondensible gases finally escaping through the flue. This is essentially the process as carried on at Idria and New Almaden; likewise at Almaden, except that the vapors are passed through the so-called *aludels*, consisting of cylinders adapted to each other, first in a descending and then in an ascending direction, where most of the mercury is condensed and collects in a gutter placed under the angle, the remainder being condensed in a large terminal chamber, from which the gases pass into the flue. In the Palatinate the cinnabar is mixed with lime, and in Bohemia with hammerslag and then distilled, sulphide of calcium remaining behind in the former, and sulphide of iron in the latter case.

Mercury appears in commerce in cylindrical iron flasks containing 75 pounds each. In this condition it still contains small quantities of other metals, principally lead, which, however, do not interfere with its uses in the silvering of looking-glasses, in the amalgamation process for the extraction of gold and silver, nor in the preparation of some chemicals. For barometers and thermometers, as well as for some pharmaceutical preparations, a purification of the metal is required or advisable, and may be effected by distillation or by the following process directed in the German Pharmacopœia:—

HYDRARGYRUM DEPURATUM.—Take of Mercury one hundred parts; Nitric Acid, Distilled Water, each five parts. Introduce them into a suitable vessel, and digest for three days, shaking frequently. Having poured off the acid liquid, wash well the mercury with distilled water, and dry it completely.

The operation is best conducted in a broad glass or porcelain vessel, so as to expose a very large surface of the metal to the action of the dilute acid. The lead, being far more easily oxidized and dissolved than the mercury, is thereby removed, though a little of the latter likewise passes into solution. After washing, most of the water may be removed by bibulous paper.

Properties.—Mercury is solid at a temperature of —39.44° C. (—39° F.), and crystallizes in octohedrons and needles, which are ductile and may be cut with a knife. At the ordinary temperature it forms a bright silvery liquid, which is very cohering, and not adhering to glass, unless it be impure, when small globules will *tail* or leave a streak upon it. When triturated with sugar, fat, various salts, oil of turpentine, etc., it is converted into a gray powder consisting of minute globules separated by the foreign substances, and running together again on their removal; this finely divided state is called the *extinction* or *killing* of mercury, and is accomplished in making mercurial ointment and several other officinal preparations. Mercury has at 4° C. (39.2° F.) the specific gravity 13.59, and at 15° C. (59° F.) 13.57. It boils at about 350° C. (662° F.), but volatilizes very slowly even at the ordinary temperature. It is permanent at the ordinary temperature, the whitish pellicle which forms upon the surface of commercial mercury being due to the presence of foreign metals (lead, zinc, etc.). It unites directly with chlorine, bromine, and iodine, and dissolves even in dilute nitric acid with the evolution of nitric oxide. Boiling hydrochloric and dilute sulphuric acids are without action upon it; but hot concentrated sulphuric acid dissolves the metal, sulphurous acid being given off. When heated to near its boiling point in contact with the atmosphere, it combines with oxygen, forming scales of red oxide.

Tests.—The purity of mercury is ascertained from its behavior and properties as described above. When some mercury is agitated for a while with the officinal solution of ferric chloride, which is free from ferrous chloride, the liquid should afterwards not yield a blue precipitate on the addition of potassium ferridcyanide, which would result through the solution of a foreign metal and the reduction of some ferric to ferrous chloride; nor should the liquid, if necessary after being acidulated with muriatic acid, yield more than a mere trace of a colored precipitate on the addition of hydrogen sulphide.

OXIDES AND SALTS.—Mercury unites with oxygen in two proportions and forms two series of salts, the *mercurous* and *mercuric*. All soluble salts of mercury are poisonous, have an acid reaction upon test-paper and a strongly metallic taste. The normal salts are usually white, and the basic salts yellow; treated with stannous chloride, phosphorous or sulphurous acid, or other deoxidizing agents, they are blackened and finally reduced to metal. Their solutions deposit a silvery coating of metallic mercury upon a bright piece of metallic copper, and yield black precipitates with sulphuretted hydrogen and white ones with sodium phosphate. *Mercurous* salts yield black precipitates with potassa, ammonia, and, on boiling, also with alkaline carbonates. Muriatic acid causes a white precipitate of calomel, and potassium iodide separates a greenish-yellow deposit. *Mercuric* salts yield with potassa or soda yellow, with ammonia and ammonium carbonate white, and with potassium or sodium carbonate red-brown precipitates. Muriatic acid does not disturb the solutions; potassium iodide causes a scarlet-red precipitate, which is soluble in an excess of either solution. All compounds of mercury are either volatilized or decomposed by heat.

Pharmaceutical Uses.—The following chemical compounds of mercury are officinal: Hydrarg. chlorid. corros. (perchloridum), Hydrarg. chlorid. mite (subchloridum), *U. S.*, *Br.;* Hydrarg. cyanidum, *U. S.;* Hydrarg. iodidum rubrum, Hydrarg. iodidum viride, Hydrarg. oxidum flavum, Hydrarg. oxid. rubrum, *U. S.*, *Br.;* Hydrarg. sulphas, *Br.;* Hydrarg. sulphas flava, Hydrarg. sulphuretum rubrum, *U. S.;* Hydrargyrum ammoniatum, *U. S.*, *Br.;* also the solutions: Liquor arsenici et hydrarg. iodidi, *U. S.;* Liquor hydrarg. nitratis (nitrat. acidus), *U. S.*, *Br.;* Liquor hydrarg. perchloridi, *Br.*

The following pharmaceutical preparations contain mercury chiefly uncombined: Emplast. ammoniaci cum hydrargyro, Empl. hydrargyri, Hydrargyrum cum creta, *U. S.*, *Br.;* Linim. hydrargyri, *Br.;* Pilul. hydrargyri, *U. S.*, *Br.;* Suppositoria hydrargyri, *Br.;* Unguent. hydrargyri, *U. S.*, *Br.;* Unguent. hydrarg. comp., *Br.*

The following pharmaceutical preparations contain combined mercury: Lotio hydrarg. flava, Lotio hydrarg. nigra, *Br.;* Pilul. antimonii comp. (hydrarg. subchloridi comp.), *U. S.*, *Br.;* Pilul. catharticæ comp., *U. S.;* Unguent. hydrarg. ammoniati, *U. S.*, *Br.;* Unguent. hydrarg. iodidi rubri, *Br.;* Unguent. hydrarg. nitrat., *U. S.*, *Br.;* Unguent. hydrarg. oxidi flavi, *U. S.;* Unguent. hydrarg. oxidi rubri, *U. S.*, *Br.;* Unguent. hydrarg. subchloridi, *Br.*

Physiological Action.—In the following account we shall consider the action and uses of metallic mercury, and the effects which are common to it and a certain number of the compounds of the metal, referring the reader to those compounds for a description of their special operations.

On Animals.—It has always been well known that mercury in every form is destructive of life in plants, insects, and small animals, and that its vapors prevent the development of the embryo in seeds and eggs. In the neighborhood of furnaces for smelting mercurial ores, animals become cachectic; cows abort, and fish in contaminated streams lose their natural color. It has also long been known that mercury rubbed into the skin of an animal may destroy its life after having deranged all the functions, and may be extracted from the blood and tissues after its death, and from its secretions during life. Injected into the veins, it accumulates in the lungs on the venous side of the pulmonary circulation, and occasions there the formation of small abscesses; a similar effect in remote portions of the body is produced by the injection of metallic mercury into the arteries.

On Man.—Metallic mercury has frequently been swallowed in quantities varying from several ounces to two pounds, generally for the purpose of overcoming an intestinal obstruction. Occasionally, but very rarely, it has salivated, and sometimes, also, by its bulk and weight, it has ruptured a diseased bowel. It has been found repeatedly in the metallic form in the tissues of persons who had taken mercury, or breathed an atmosphere impregnated with its fumes; and it has also been demonstrated in the secretions of the skin, the kidneys, and the mucous membranes, in the blood, milk, saliva, bile, and pus. The permanence of mercury in the system of those who have used the metal, is shown by its having frequently been revived on the administration of iodide of potassium. Its absorption is illustrated on a large scale by the cachexia of the miners of, and workers in, mercury, and of the salivation and other specific effects produced on numbers of persons in an atmosphere accidentally contaminated by the emanations even of metallic mercury, and especially upon the inhabitants of districts near smelting furnaces, among whom the proportion of abortions, stillbirths, and cachectic children, is vastly in excess of that existing under other circumstances. All persons employed in trades which expose them to mercurial emanations, such as miners of mercury, gilders, mirror-makers, etc., are apt to be affected with a trembling palsy, and other and fatal disorders of the nervous system.

The action of medicinal doses of the milder preparations of mercury (as blue-mass and calomel) is first seen in an increase of the secretions, especially of the intestinal canal; but if the action be maintained, nutrition becomes impaired, as is shown by the tendency of newly formed callus and cicatricial matter to be absorbed, while the muscles waste, the skin grows pale, and œdema readily forms where the venous circulation is interrupted. These symptoms appear to denote an impaired crasis of the blood, which, indeed, is further exhibited by a tendency to ecchymoses and to hemorrhage. It would seem, that, provided the dose of mercury be small, although large enough to cure syphilitic disease, its primary effect is not to diminish, but actually to increase the proportion of the red corpuscles of the blood, no doubt by counteracting the morbid poison in that liquid. The power of mercury to lessen the coagulability of the blood makes its use injudicious when there is already a hemorrhagic tendency, and especially in females who suffer from repeated and profuse menorrhagia.

Along with the evidences of impaired nutrition just pointed out, another occurs which is peculiarly characteristic of the action of mercury. This is salivation. It is apt to be preceded and accompanied by feverishness and nervous susceptibility. The first local evidence of its occurrence is usually a metallic taste in the mouth, with soreness of the teeth when the jaws are struck together. The breath has a characteristic fetor. A red line may be observed along the gingival attachments of the lower incisors, and then of the remaining teeth. The gums, lips, cheeks, tongue, and fauces are more or less tumefied, and the tongue has a sodden look, with an impress of the teeth upon its edges. The salivary glands are swollen and tender, and there flows from the mouth a transparent, viscid liquid, of alkaline reaction, and a penetrating smell. When salivation is excessive and prolonged, ulcers are apt to attack the gums, cheeks, and fauces, and in healing may cause the adhesion of contiguous parts; the breath becomes insufferably fetid, the teeth loosen, and may fall out, and caries may attack the remaining teeth, and even the maxillary bones. Children and infants are seldom salivated, but when they are so the effects are apt to be very severe. Salivation is partly a reflex effect of the ulcerative processes in the mouth, and partly the sign of a direct action upon the salivary glands which they share with all the glands of the body.

Under the constitutional operation of mercury the appetite fails, and the bowels readily grow loose; it is probable that the pancreatic secretion is augmented, and very improbable that the secretion of bile is increased. The belief which was general and implicit that mercury had some mysterious control over the liver, through which it increased or diminished the secretion of that organ at the physician's will, has given place to a very general scepticism in regard to the matter; and, indeed, it is asserted that, compared with croton oil, podophyllin, rhubarb, senna, colchicum, scammony, and taraxacum, mercury manifests the least degree of cholagogue operation. Upon the nervous system the action of mercury is depressing, occasioning a morbid susceptibility to cold, and a state of mental uncertainty and restlessness, with feebleness of the intellectual powers. It also appears to be injurious to the fœtus in utero, and to favor miscarriage. Among its constitutional effects are cutaneous eruptions, generally in the form of eczema, sometimes in that of a febrile rubeoloid eruption, and more rarely as an eruption of bloody bullæ. Deep, foul, and intractable ulcers sometimes occur; they are most common within the cavity of the mouth and throat, and may prove fatal by hemorrhage or by exhaustion, the ulcerative process sometimes destroying the cheeks and the soft parts of the throat. It appears probable that mercury may give rise to periosteal nodes which sometimes advance to the destruction of the bones. Finally, when administered too freely, and for too long a period, mercury may produce a general cachexia, of which the chief phenomena are these: the muscles lose their firmness, and waste; the complexion grows pallid and earthy, the breath fetid, and the urine readily becomes so, and usually there is diarrhœa. The gums grow spongy, the hair falls out, the bones and joints suffer dull pains, œdema of the ankles or general dropsy may supervene; hemorrhage from the nose, bowels, kidneys, or reopened wounds takes place, and hectic fever, with tubercular consumption, may terminate life.

To remedy, as far as possible, these mischiefs, during a treatment by mercurials, their use should be suspended in season, and attempts made by means of iodide of potassium, purgative mineral waters, and diaphoretics, to hasten the elimination of the poison. The regimen should consist of nutritious food, protection from cold and dampness, and the cautious administration of iron. The local ulcerative lesions should be treated with washes of muriatic acid, chlorate of potassium, and nitrate of silver.

The mode of action of mercury which may be inferred from the preceding summary of its effects is the following: Being essentially non-nutritive, yet penetrating every tissue, it probably acts in small and transient doses as a stimulant of all organic processes; but in a little greater proportion and by continued use it impairs nutrition, hindering the formation of tissue on the one hand, and, on the other, hastening its destruction and elimination. At the same time it augments more or less the glandular secretions. It diminishes the proportion of fibrin and of the red corpuscles in the blood. Thus, hindering nutrition in all its steps, mercury causes the waste of all the tissues, and especially of those least organized, as cicatrices and callus, and favors the removal of all plastic exudations. These effects are essentially morbid and destructive, and are only incidentally, and within varying limits, salutary.

Medical Uses.—It is probable that as much injury has been inflicted by the use of mercury in primary *syphilis* as good has been accomplished by its administration in the constitutional forms of the disease. And when it is considered that every simple sore following a suspected coition was apt to be treated as syphilitic, by mercurialization of the system, it may be a question whether, on the whole, the medicine has not been more mischievous than useful. In regard, even, to true chancres, although mercurials will sometimes hasten their cure by lessening their induration, and may thereby postpone constitutional infection, it does not in any case prevent that result, nor even the enlargement of the inguinal glands. Moreover, in certain states of the primary sore, and of the patient's system, mercury aggravates the disease. Such is the case when the skin around the sore is very red, swollen, tense, and painful, or shows a tendency to gangrene; when the patient is anæmic, scrofulous, tuberculous, or scorbutic, or has been an habitual drunkard. Opinions differ in regard to treating pregnant syphilitic women with mercury; the better opinion is in favor of this measure for the sake of the child as well as the mother. But this judgment refers to secondary, not to primary syphilis.

Until comparatively recent times the treatment of constitutional syphilis consisted in the administration of mercury for the purpose of exciting profuse salivation, which was maintained for four or five weeks at a time. The disastrous consequences of this method, which had no other reason for its use than the hypothesis that the syphilitic poison was to be eliminated with the saliva, and which thus illustrated the folly and dangers of *a priori* therapeutics, caused it at last to be abandoned, and it is now certain that mercury cures syphilis without salivation better than by means of it. The commencing dose of mercury should always be small, and gradually increased until its effects on the disease begin to appear or some soreness of the gums occurs; it should then be continued, or slightly diminished, or even temporarily suspended if the symptoms begin to decline; but it should never be abandoned as long as any trace of the disease remains. This often involves a course of six months' duration, and sometimes a much longer one; but it is safe, while the method of treatment with large doses of mercury is always hazardous.

The treatment by inunction with mercurial ointment may be referred to here. It is one of the oldest modes of employing mercury in this disease, and is still a favorite hospital method; but it is too filthy for private practice, and it necessarily betrays the nature of the patient's disease. It, moreover, ruins all the body and bed clothing which is used. The advantages attributed to it are that it is much less likely to disorder the bowels than mercury taken by the mouth; it cures, also, more quickly and with less risk of injuring the constitution. It is chiefly appropriate to the treatment of syphilitic affections of the skin; and next to these, but far less efficiently, to ulcerated states of the mouth and throat, and still less to syphilitic disorders of the nervous system. Syphilis of the bones and their annexes is more successfully treated with iodide of potassium. Before commencing mercurial inunction, the patient should live for some days on simple food, use laxative medicine, and cleanse the skin thoroughly by warm bathing. Immediately afterwards, in bed, or near a warm fire in winter, the ointment should be methodically rubbed into the skin with the hand covered with a caoutchouc glove or a piece of softened pig's bladder. The places selected for friction should be used alternately or in succession, as the thighs, the armpits, the legs, the arms, etc., and if the part is hairy, it should be shaven, and the frictions made in the direction of the hairs. About two drachms should be rubbed in daily for five or six days, at the end of which time the patient should have a warm bath with soap, and be allowed to quit his bed, but warmly clothed. After an interval of a week the same discipline should be renewed, and this generally suffices for the cure. The result is supposed to be quickened by the use of sudorific diet-drinks, such as the compound decoction of sarsaparilla. Mercurial inunction of syphilitic infants is conveniently performed by enveloping the trunk of the patient with a flannel band that has been smeared with mercurial ointment. The use of other mercurial preparations in syphilis is treated of in connection with those preparations.

In the greater number of *febrile* and *inflammatory* affections calomel is the form of mercury usually selected by those who believe mercurials appropriate to these diseases, but sometimes its action is supplemented by the use of mercurial ointment, as in acute *meningitis*, *pericarditis*, *hepatitis*, etc. In these cases it is generally applied upon a blistered surface. In *acute dyspepsia*, often accompanied with jaundice, and produced by excesses in eating and drinking and a constipated habit, a superstitious belief prevails among English physicians and their American copyists, that the sovereign and specific remedy is blue pill followed by a saline cathartic. Other nations, it is true, relieve such symptoms by the saline alone, or by rhubarb and aloes along with it. Whenever congestion of the liver is associated with enlargement of the spleen, the administration of blue pill or other mercurial is extremely apt to be followed by profuse salivation, and even gangrene of the mouth. An apparent exception to this rule is the cure of malarial enlargement of the *spleen* by the external use of biniodide of mercury. Metallic mercury has been used to overcome *intestinal obstructions* supposed to be formed by invagination; and also to expel intestinal worms. In neither case is its utility proven. Mercurial ointment is probably the best remedy for *ascarides of the rectum.* It is generally used as an application around the eye in the treatment of acute *iritis*, along with the internal use of calomel. It is a valuable auxiliary also in the treatment of true *croup* (pseudomembranous laryngitis), when it should, from the commencement of the attack, but only in primary and sthenic cases, be rubbed into the axillæ and the groins. It relieves the pain and is said to subdue the inflammation in *paronychia;* it has an analogous effect in *erysipelas;* and there is reason to believe that it checks the development of *smallpox* pustules, and thereby tends to prevent their pitting. Metallic mercury has been successfully used to amalgamate with a *gold ring* which had become too tight for the finger, and to render it so brittle that it readily broke under pressure. The ring in such cases should first be cleansed with alcohol or ether.

Metallic mercury is seldom given internally, except in the modified form of blue pill (see Pil. hydrargyri).

HYDRARGYRUM AMMONIATUM, *U. S.*, *Br.*—AMMONIATED MERCURY.

Hydrargyrum præcipitatum album, P. G.; *Hydrargyrum amidato-bichloratum (ammoniato-muriaticum)*, *Hydrargyri ammonio-chloridum*, *Mercurius præcipitatus albus.*—*White precipitate*, E.; *Oxychlorure ammoniacal de mercure*, *Mercure précipité blanc*, Fr.; *Weisser Quecksilberpräcipat*, *Quecksilber-Chloridamidid*, G.

Formula NH_2HgCl. Molecular weight 251.5.

Preparation.—Take of Corrosive Chloride of Mercury six troyounces; Water of Ammonia eight fluidounces; Distilled Water eight pints. Dissolve the corrosive chloride of mercury in the distilled water, with the aid of heat, and to the solution, when cold, add the water of ammonia, frequently stirring. Wash the precipitate with water until the washings become nearly tasteless, and dry it. *U. S.*

Take of Perchloride of Mercury three ounces; Solution of Ammonia four fluidounces; Distilled Water three pints. Dissolve the perchloride of mercury in the water with the aid of a moderate heat; mix the solution with the ammonia, constantly stirring; collect the precipitate on a filter, and wash it well with cold distilled water until the liquid which passes through ceases to give a precipitate when dropped into a solution of nitrate of silver acidulated by nitric acid. Lastly, dry the product at a temperature not exceeding 212° F. *Br.*

In following the above processes, one-half of the ammonium has two atoms of the univalent hydrogen replaced by one atom of the bivalent mercury, producing the radical mercur-ammonium (NH_2Hg), which is a monad like ammonium, and combines with one atom of chlorine to form the white precipitate; the other half of the ammonium unites with the other atom of chlorine contained in the mercuric chloride to ammonium chloride which remains dissolved; water is likewise produced, by the reaction, which is explained by the equation, $HgCl_2 + 2NH_4HO = NH_2HgCl + NH_4Cl + 2H_2O$. The ammonium chloride requires to be washed out, as long as the washings have a saline taste or cause a white precipitate with acidulated solution of silver nitrate. Cold water must be used for the purpose, and the washing not be continued too long, to prevent the precipitate from acquiring a yellowish tint.

Properties and Tests.—Ammoniated mercury is a white powder or is often in friable masses, having an earthy afterwards metallic taste. It is insoluble in ether, alcohol, and water, but yields with boiling water a lemon-yellow basic compound, ammonium chloride being dissolved. When heated, it volatilizes without fusion and without leaving any residue (absence of non-volatile compounds). Potassa solution or lime-water evolves ammonia and colors the powder yellow; it is soluble in hot solutions of ammonium salts and in hydrochloric, as well as in nitric and acetic acids, without effervescence (absence of carbonates). The solutions yield white precipitates with potassa (ammoniated mercury) and silver nitrate (silver chloride). The solution in acetic acid yields no precipitate with sulphuric acid (absence of lead), and when treated with an excess of hydrogen sulphide, a black precipitate is obtained, and a colorless filtrate, which on being acidulated with muriatic acid, evaporated to dryness, and ignited, is not charred (absence of starch), and leaves no fixed residue (absence of zinc, calcium, etc., salts).

Fusible white precipitate, which was formerly considered to be identical with the preceding, until Wöhler and Kane proved its difference, was prepared by dissolving ammonium and mercuric chlorides in water and precipitating with sodium carbonate. Thus obtained it has the composition $(NH_3)_2HgCl_2$ or perhaps $NH_4Cl.NH_2HgCl$, and differs from the officinal ammoniated mercury in fusing, when heated, to a yellowish liquid, evolving nitrogen and ammonia, and yielding a transparent and an opaque white sublimate.

Off. Prep.—Unguentum hydrargyri ammoniati, *U. S.*, *Br.*

Medical Action and Uses.—The insolubility of ammoniated mercury in water and even in the normal acid contents of the stomach renders it a less active irritant than some other mercurial salts. Sometimes its irritant operation seems to be attributable to defects in its manufacture, or to its exposure to light, whereby a portion of it is converted into corrosive sublimate. Certainly in several cases it has occasioned all the symptoms of an irritant poison, with the specific effects of mercury, and a fatal result at last. It is not used internally as a medicine, but its ointment, which is officinal, is employed in *ophthalmia* and *skin diseases*.

HYDRARGYRUM CUM CRETA, *U. S.*, *Br.*—MERCURY WITH CHALK.

Mercure avec la craie, *Poudre de mercure crayeux*, Fr.; *Quecksilber mit Kreide*, G.

Preparation.—Take of Mercury three troyounces; Prepared Chalk five troyounces. Rub them together until the globules cease to be visible, and the mixture acquires a uniform gray color. *U. S.*

Take of Mercury by weight one ounce; Prepared Chalk two ounces. Rub the mercury and chalk in a porcelain mortar until metallic globules cease to be visible to the naked eye, and the mixture acquires a uniform gray color. *Br.*

When certain substances are triturated with metallic mercury, they acquire a gray tint, and the metallic lustre of the mercury gradually disappears in consequence of its fine division (see page 722). To effect this with chalk alone is a tedious operation, to shorten which Dr. Stewart (1843) proposed to triturate, first with resin, then with chalk, and finally to remove the resin by alcohol; Dr. Mettauer suggested the use of a mixture of starch and chalk, kept damp by a little water during the trituration; and W. Hewson (1850) proposed to shake the metal with a portion of the chalk in a bottle until extinguished, and then to add the remaining powder. This process is followed on a large scale, a barrel or other suitable vessel containing the mixture being turned on its axis; or it is combined with trituration, a ball being also introduced into a vessel having a somewhat eccentric motion. Dr. Squibb (1857) constructed an apparatus in which the mercury is shaken with honey or syrup, and, when completely extinguished, mixed with the chalk, most of the sugar being afterwards washed out with cold water; this process yields a very pure product, but the globules are larger than in the products of the other processes, and the powder cannot be triturated with pressure without separating some metallic globules. W. E. Bibby (1876) has suggested a method which enables the pharmacist to prepare this medicament without the expenditure of much time by substituting sugar of milk for about one-fifth of the chalk, which greatly facilitates the fine division of the metal.

Properties and Tests.—Mercury with chalk is a gray powder free from grittiness, from which the mercury is volatilized by heat. When treated with an excess of diluted acetic acid, the chalk dissolves with effervescence, metallic mercury being left behind; the solution thus obtained usually yields a faint turbidity on the addition of hydrochloric acid, calomel being formed with the *mercurous oxide* dissolved by the acid. The presence of this oxide is disregarded by the British Pharmacopœia, which requires the preparation to be partly dissolved by dilute hydrochloric acid; any mercurous oxide present would be converted into calomel, and remain with the finely divided undissolved mercury. Both Pharmacopœias require the preparation to be free from *mercuric oxide*, which would be detected in the clear solution containing hydrochloric acid by a white or gray precipitate with stannous chloride, or by a black one with hydrogen sulphide. Dr. Squibb (1857) determined in a sample the presence of 1.2 per cent. of mercurous and 1.44 per cent. of mercuric oxide; Jos. P. Remington (1869) found even 14.3 and 25.7 per cent. of the latter in two samples taken from dispensing bottles. These results fully explain the violent action which has been occasionally observed. The preparation should be examined from time to time to insure its good qualities.

Medical Action and Uses.—This preparation seems to be only metallic mercury maintained in a state of minute subdivision by chalk. The proportion of the latter ingredient is too small to be regarded as of any direct therapeutic value, for in eight grains of the compound there are three of mercury and five of chalk; and in the dose of two or three grains, in which it is generally administered, any immediate action, except that which belongs to an unirritating insoluble powder, can scarcely be admitted. Mercury with chalk is chiefly used in the *bowel complaints* of children, especially when the discharges are colorless and sour, and is very generally believed to cause a secretion of bile, and thus restore the normal action of the alimentary canal. Of this action, as elsewhere stated (Hydrargyrum), no proof exists. The chief good it does is very probably to take the place of larger doses of more perturbative medicines. *Dose*, from three to ten grains.

HYDRASTIS, *U. S.*—HYDRASTIS.

Rhizoma hydrastis.—Golden seal, Yellow root, Yellow puccoon, Orange root, Indian dye, Indian turmeric, E.; *Racine d'hydrastis de Canada*, Fr.; *Canadische Gilbwurzel*, G.

The rhizome with the rootlets of Hydrastis Canadensis, *Lin.*, s. Warnera Canadensis, *Miller*. Bentley and Trimen, Med. Plants, 1.

Nat. Ord.—Ranunculaceæ, Helleboreæ.

Origin.—This perennial is indigenous to Canada and the United States east of the Mississippi; it grows in rich woodlands, and in the Southern States is confined to the mountainous districts. It has a low stem, and at the summit two round heart-shaped leaves and a single greenish-white flower, and produces a crimson fruit composed of 12 or more one- or two-seeded berries.

Description.—The rhizome is 1 to 2 inches long, about $\frac{1}{4}$ inch thick, oblique, with several short branches, terminated by a broad concave scar, somewhat flattened, annulate from the leaf-scars, longitudinally wrinkled, and below beset with many thin fragile rootlets 3 to 5 inches long, containing a thin triangular or quadrangular ligneous cord and a thick bright yellow bark. The rhizome is externally brownish-gray with a yellow hue, hard, and breaks with a short waxy fracture of a bright reddish- or brownish-yellow color; the bark is about $\frac{1}{8}$ the thickness of the rhizome; the central pith and medullary rays are broad, and the yellowish wood consists of 8 to 12 narrow wedges, or, near the base of the branches, of a few linear and several larger irregular bundles. Golden seal has a slight odor, and a bitter taste free from any marked astringency.

Constituents.—Besides the common constituents, like starch, sugar, etc., A. B. Durand (1851) found in it a yellow coloring matter and a white alkaloid *hydrastia.* The former was recognized by Mahla (1862) as *berberina*, the hydrochlorate of which has been used by eclectic practitioners under the incorrect name of *hydrastin.* Perrins (1862) obtained 4 per cent. of the crude hydrochlorate (see Berberis, p. 282) and 1.5 per cent. of hydrastia, which was analyzed by Mahla (1863). *Hydrastia*, $C_{22}NH_{23}O_6$, is contained in the mother liquor from the preparation of berberina, and obtained by diluting the liquid with water, evaporating the alcohol, neutralizing carefully with ammonia, filtering from the precipitated resin, etc., and precipitating with ammonia; the fawn-colored deposit is purified by animal charcoal and recrystallization from hot alcohol. It is in white shining quadrangular prisms, which fuse at 135° C. (275° F.), are readily soluble in alcohol, ether, chloroform, and benzol, insoluble in water, colored red by nitric acid, brown-red by sulphuric acid and potassium chromate, and yield with acids soluble and very bitter salts. From the investigations of A. K. Hale (1873) and J. C. Burt (1875) it appears that the hydrastia of former investigators was not quite pure, but probably mixed with a *third alkaloid*, which Hale obtained of a dark yellow color, and Burt crystallized as sulphate in colorless needles; warmed with nitric acid it turns red, with sulphuric acid reddish-brown, and the solution of its hydrochlorate is colored dark brown to black by ferric chloride; it is present in smaller quantity than hydrastia.

Off. Prep.—Extractum hydrastis fluidum, *U. S.*

Medical Action and Uses.—The bitter taste of this root probably led to its employment as a stomachic tonic, and in mild cases of intermittent fever. A variety of incongruous virtues have been attributed to it by the ignorant. It does not deserve to rank among officinal medicines. A decoction is made by boiling an ounce of the bruised rhizome in a pint of water for fifteen minutes. Of this one or two fluidounces may be taken several times a day.

HYDROCOTYLE.—WATER PENNYWORT.

Indian pennywort, E.; *Bevilacqua*, Fr.; *Wassernabel*, G.

Hydrocotyle asiatica, *Lin.* Bentley and Trimen, Med. Plants, 117.

Nat. Ord.—Umbelliferæ, Orthospermæ.

Description.—A low, creeping perennial, which is indigenous to the tropical and subtropical regions of Asia, Africa, and America. The leaves are smooth, situated in tufts on the nodes of the stem, have petioles with a sheathing base, are roundish-reniform in outline, with a somewhat crenate margin, about an inch broad, rather thick, radiately veined, and dark green. The pink-colored flowers are in small umbellate clusters of about three, and produce small, laterally flattened, suborbicular fruits without oil tubes. The plant is inodorous, but on bruising the fresh leaves a peculiar odor is developed; the taste is bitterish and pungent.

Constituents.—Lépine (1855) isolated *vellarin*, which he regarded as the active principle. It is an oily liquid, having a bitter taste, a strong, peculiar odor, becoming viscous on exposure, insoluble in potassa solution, and soluble in ammonia, diluted alcohol, and ether. He obtained from the dried leaves 13 per cent. of ash.

Allied Plants.—Most other species of this genus appear to possess somewhat similar sensible properties. The North American species H. ranunculoides, *Lin.*, and H. americana, *Lin.*, have likewise reniform leaves, those of the former being 3- to 7-cleft; those of the latter, thin, crenate-lobed, the lobes of both being crenate.

Peltate leaves, with doubly crenate margins, are met with in the European H. vulgaris, *Lin.*, which has 5-flowered umbellate clusters, and in the American H. umbellata, *Lin.*, which has the umbellate clusters about 20-flowered.

Medical Uses.—About 1852 this medicine, which had long been employed in India in the treatment of febrile diseases and as a diuretic, was announced by a French physician in the Mauritius to have cured a case of *leprosy*. Other reports of a favorable character proceeded from different quarters, some of them containing specific details of the cure of this fatal affection in numerous instances; and then it fell into complete disfavor, as other medicines of like pretensions had done. Meanwhile it was found an efficient remedy in *scaly diseases* of the skin, including those of syphilitic origin, in chronic *eczema*, in scrofulous and other *ulcers*, and chronic *rheumatism*. The powdered root has been prescribed in doses of three grains several times a day; and an alcoholic extract in doses of half a grain.

HYDROGENII PEROXIDUM.—PEROXIDE OF HYDROGEN.

Peroxyde d'hydrogène, Fr.; *Wasserstoffhyperoxyd*, G.
Formula H_2O_2. Molecular weight 34.

Origin.—Thénard (1818) discovered this compound, which has also been called *oxygenated water* and *oxygen hydrate*, by acting with dilute acids upon peroxide of barium. Meissner (1863) proved its presence in the rain-water collected during thunder storms, and this observation has since been corroborated by Schönbein (1869), Struve, and others. Houzeau (1868) did not succeed in finding it.

Preparation.—The preparation of peroxide of hydrogen in the pure state is a difficult process, and depends upon the decomposition of barium peroxide by hydrochloric acid in the presence of ice-cold water, and the precipitation of the newly-formed barium chloride by means of sulphate of silver. Instead of hydrochloric, carbonic or hydrofluoric acid may be employed; or peroxide of potassium may be acted upon by hydrofluosilicic acid. The *barium peroxide* is obtained by conducting oxygen gas over pure baryta heated to redness.

Properties.—The aqueous solution of peroxide of hydrogen may be concentrated by the aid of the air-pump, until its spec. grav. is 1.452. It then forms a colorless, transparent liquid, which does not congeal at —30° C. (—22° F.), and volatilizes in vacuo, slowly and without decomposition, at the ordinary temperature. But when heated or brought into contact with charcoal, silver, gold, the platinum metals, the oxides of manganese, or various other compounds, the peroxide is decomposed with explosive violence, and in the presence of the oxides of the metals mentioned these are reduced to the metallic state. Some other bodies act less energetically, or are oxidized. Litmus and turmeric paper are gradually bleached. Peroxide of hydrogen is without odor, and has a harsh and bitter taste; applied to the skin, it colors it white, and produces violent itching.

Composition.—Peroxide of hydrogen is the *binoxide* or *dioxide of hydrogen* H_2O_2, and has also been viewed as a hydrate of oxygen, $O.H_2O$. The oxygen, which is given off under the conditions mentioned above, has been regarded by Schönbein and others as a peculiar modification, which has been called *positive oxygen* or *antozone*, to distinguish it from *ozone*, or oxygen in the negative condition. The correctness of these distinctions, however, is denied by many investigators.

Ethereal solution of hydrogen peroxide has been prepared by Böttger, by adding impure sodium peroxide (obtained by the burning of sodium) to a cold mixture of 1 part of sulphuric acid and 24 parts of water, with the precaution of avoiding an elevation of temperature; the mixture is then repeatedly agitated with ether. Such a solution was used by Dr. Richardson (1869) under the name of *ozonized ether*. He found that the addition of a little alcohol to the ether facilitates the absorption of the peroxide, and that the combination of the latter with the ether and some water, although very slight, is persistent, for the mixture was sent to Australia without deterioration.

Medical Action and Uses.—Upon theoretical grounds this compound was introduced as a cure for *diabetes*, but it signally failed after a sufficient trial by competent judges. It is unnecessary to enumerate the other diseases in which it proved to be equally valueless as an internal remedy. Externally it has been applied to *ulcers* of various kinds. It seems to promote their healing both by stimulating them and coagulating their secretions; and in the case of syphilitic sores it is thought to disinfect their virus. It has been used in an ointment (one part to seven of lard) to anoint the skin of *scarlet fever* patients, with the alleged result of diminishing the mortality, and preventing the spread of the disease. There is no sufficient ground for this opinion.

HYOSCYAMI FOLIA, *U. S.*, *Br.*—HYOSCYAMUS LEAVES.

Herba hyoscyami.—*Henbane leaves*, E.; *Feuilles de jusquiame noir*, Fr.; *Bilsenkraut*, G.

The leaves of Hyoscyamus niger, *Lin.* Steph. and Church, Med. Bot., plate 9.

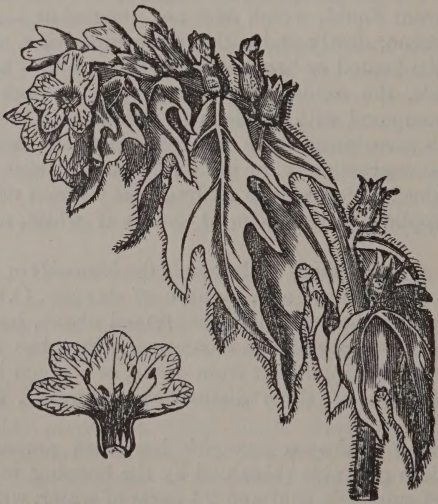
HYOSCYAMI SEMEN, *U. S.*—HYOSCYAMUS SEED.

Semen hyoscyami, P. G.—*Henbane seed*, E.; *Semences de jusquiame noir*, Fr.; *Bilsensamen*, G.

The seeds of Hyoscyamus niger, *Lin.* *Nat. Ord.*—Solanaceæ.

Origin.—The typical form of henbane is biennial, grows in sandy soil and waste places throughout the greater portion of Europe, and eastward and southward to Siberia, Northern India, and Egypt, and has been naturalized in North America from the New England States to Michigan. It is 2 to 3 feet high, covered

Fig. 87.



Hyoscyamus niger, *Lin.*

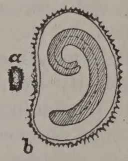
with long, jointed, glandular hairs, and has the numerous nearly sessile flowers in a long, leafy, one-sided spike-like raceme. The funnel-shaped five-lobed corolla is about 1¼ inch long and wide, pale yellow, with purple veins, and a similar colored base. The capsule (pyxis) is inclosed in the bell-shaped calyx, about ½ inch long, dehiscent near the top by a cap, two-celled, and contains numerous seeds. An annual variety, H. agrestis, *Kitaibel*, is not over a foot high, less villous, and has smaller leaves and fewer flowers; if the latter are veinless, the plant is H. pallidus, *Willd.*

H. albus, *Lin.*, and H. aureus, *Lin.*, of Southern Europe, are occasionally employed there, but are less active. H. physaloides, *Lin.*, is used in Siberia.

Description. 1. THE LEAVES.—Taken from different parts of the stem, they vary from 2 to 10 inches in length, and 1 to 4 inches in width, the lower leaves being stalked, the upper sessile and amplexicaul. They are ovate to ovate-oblong in shape, on each side with one (upper leaves) to five coarse sinuate teeth or lobes, which are rather acute and oblong or triangular. In the dry state they are of a grayish-green color, hairy above, more densely so on the lower surface and upon the prominent broad midrib. Some of the characteristic flowers or capsules or both may usually be found with the drug, the heavy narcotic odor of which is diminished by drying, but becomes more prominent again when the leaves are moist. The taste is bitter and somewhat acrid. Being very hygroscopic, the leaves should be kept in a dry place.

2. THE SEEDS.—They are about ½ line long, roundish reniform, flattened, with a gray-brown, finely and densely rough-pitted testa, containing a whitish oily albumen, which incloses a curved embryo of the shape of the figure 9. The hilum is in the curved side of the seed. The seeds are without odor, and have an oily, bitter, and acrid taste.

Fig. 88.



Hyoscyamus Seed.—*a*, slightly magnified; *b*, longitudinal section.

Belladonna seeds are of about the same size and shape, but are of a red-brown color.

Constituents.—Brandes (1820) obtained from the seeds 25 per cent. of a bland, limpid, and colorless oil, of which about 20 parts were readily soluble in absolute alcohol. Their most important constituent, however, like that of the leaves, is the alkaloid *hyoscyamia*, which was observed by Brandes, and again obtained by Geiger and Hesse (1833), and by Kemper (1866), in a purer condition from both the leaves and seeds. More complete investigations were made by Höhn (1870 and 1871), who deprived the seeds of the oil by ether, and then exhausted them by alcohol slightly acidulated with sulphuric acid. The tincture was distilled and evaporated, filtered, almost neutralized with soda, and precipitated by tannin; the precipitate, still moist, was mixed with lime, exhausted with alcohol, the solution again acidulated, concentrated, shaken with ether, to remove oil and color, decomposed by soda, and the alkaloid exhausted by ether. The filtrate from the tannin precipitate and the fixed oil retained some of the alkaloid, of which altogether 0.0453 per cent. was obtained. Thibault (1875) received it in silky crystals on the spontaneous evaporation of the chloroformic solution.

Hyoscyamia, $C_{15}H_{23}NO_3$, is soft like wax, containing wart-like crystals, fusible at 90° C. (194° F.), and then emitting a peculiar odor, suggesting that of salicyl compounds, readily soluble in the ordinary solvents, of a strongly alkaline reaction, and yielding with acids crystallizable salts. Boiled with baryta solution it is decomposed into *hyoscinic acid*, $C_9H_{10}O_3$, which crystallizes in needles, and has an odor somewhat like that of benzoic acid, and into *hyoscina*, $C_6H_{13}N$, which is a volatile alkaloid of a slight narcotic odor.

Höhn (1870) obtained also a bitter glucoside, *hyoscypicrin*, $C_{27}H_{52}O_{14}$, which has a bitter taste, is neutral, soluble in alcohol and water, and precipitated by tannin; on distilling the mother liquors with soda, some volatile bases were obtained, among them, probably, methylammonia.

Thorey (1869) states that the leaves contain the largest proportion of hyoscyamia and of potassium nitrate before flowering.

Off. Prep.—1. Of the leaves. Extract. hyoscyami, *U. S.*, *Br.*; Extract. hyoscyami alcoholicum, Extr. hyoscyami fluid., *U. S.*; Tinctura hyoscyami, *U. S.*, *Br.*

2. Of the seeds. Emulsio amygdal. comp., *P. G.* (See Mistura amygdalæ.)

Physiological Action. *On Animals.*—It is implied in the etymology of hyoscyamus that the plant may be eaten without harm by hogs; it is also said not to injure sheep or cows, nor to have much effect upon rabbits, while barnyard fowls and fish are poisoned by it. Upon dogs, hyoscyamus and its alkaloid act as they do upon man. In these animals, in cats, and various others, they produce dilatation of the pupil, and, in full doses, dryness of the mouth, and a dull or lethargic condition, with loss of power in the hinder legs. In moderate doses, they slow both respiration and circulation, rendering the pulse fuller and stronger; in full doses, they have the opposite effect. They increase the discharge of urine, from which the alkaloid can be recovered. These effects are so nearly like those occasioned by belladonna and atropia, that some pharmacologists regard the latter alkaloid and hyoscyamia as identical.

On Man.—The following effects are produced by henbane and by hyoscyamia: In full medicinal dose, the former occasions headache, pasty mouth, hoarse voice, dry throat, a warm skin, and a slower and then an accelerated pulse, while the pupil becomes dilated and the limbs give way under the body. The sense of touch is blunted, and the voluntary muscles are apt to be cramped or to be affected alternately with spasm and paralysis. No direct narcotic effect is produced in the greater number of cases, but rather a loquacious sub-delirium, which may merge into a restless and dreamy sleep. Only in large doses is it decidedly hypnotic. The power of henbane to produce a peculiar talkative and pugnacious delirium was fully described by ancient writers, and some modern observers have witnessed similar effects. It is curious that, in certain cases, although the general sensibility is impaired, severe neuralgic pains may be felt in the limbs. Continued medicinal doses tend to produce a reddish efflorescence upon the skin, which is dry and itching. When poisonous doses, on the other hand, have been taken, the skin is sometimes cool and clammy, the face pale, and the lips bluish. Notwithstanding the threatening character of the symptoms, death from this substance is extremely rare. In proportion to the dose they are less alarming in children than in adults, and especially in old persons. This peculiarity is doubtless due to the rapid elimination of the poison in the young. From an experimental point of view, it must be concluded that hyoscyamus is not a narcotic soporific, that it is anodyne or anæsthetic, that it excites the cerebral and depresses the spinal functions, and that it is a mydriatic.

Medical Uses.—At one time, hyoscyamus was believed to be a valuable remedy for *epilepsy*, but experience has shown that in the doses formerly given it is quite inert, and that even in really operative doses, its utility is limited to cases of emotional origin. Dr. Lawson, in England, has found hyoscyamia very useful in controlling violent outbreaks of *mania*, especially of the recurrent acute and subacute forms, the monomania of suspicion, and the excitement of senile dementia. It appears to be essential to the success of this treatment that the medicine should be given in a dose of not less than one grain, as in the following draught: ℞. Hyoscyamiæ, gr. j; Spt. ætheris (Br. Ph.) ♏viij; Alcoholis, ♏xxiv; Aq. fontis, ad f℥j.—M. If a smaller dose is given, it is said, cerebral excitement, without complete motor paralysis, is produced, and remains through the whole period of the operation of the medicine. In some forms of *hypochondriasis*, it seems to have been useful as a means of calming agitation. In functional *palpitation* of the heart of a purely nervous nature, it has been found beneficial, when used hypodermically, in the dose of about one-fiftieth of a grain. The same means relieve cardiac and pulmonary *asthma*. Hyoscyamia has been used in trembling *palsy* and mercurial *trembling chorea*, *locomotor ataxia*, and *tetanus*. In the first, it exerts a marked power in moderating the tremulousness, and in the second, it is alleged to have effected cures; it seems, indeed, to have cured a number of cases of chorea, of which several occurred in adults; in locomotor ataxia it palliates the spasms and the neuralgic pains, and in tetanus moderates the severity of the paroxysms. In these affections, and notably in chorea, its therapeutical action appears to be explained by its paralyzing influence upon the spinal cord, which seems to be of the same nature as that produced by conium. The *vomiting* of pregnancy, a symptom of reflex origin, has been controlled by it. It was prescribed in a solution containing five milligrammes of the alkaloid in 125 grammes of liquid, of which a teaspoonful was given every hour.

There is no doubt that hyoscyamus is anodyne, and apparently by its operation upon the sensitive nerves and ganglia, and not upon the cerebral organs of perception. The crushed leaves of fresh henbane are popularly applied, where the plant abounds, for the relief of local pains, and internally its preparations are of common use to allay *neuralgic* and other pains that hinder sleep. It is also used to lessen the tendency to gripe of certain cathartics given in a pilular form, for it has the advantage of tending to relax rather than confine the bowels. Like the other mydriatics, henbane is used to dilate the *pupils*. Poisoning by henbane should be treated by evacuating the stomach, applying warmth to the extremities and cold to the head, and administering stimulants, particularly coffee, and morphia hypodermically in small and repeated doses.

The *dose* of powdered henbane is stated at from five to ten grains; but this form of the medicine is rarely used. Hyoscyamia may be given in the dose of one milligramme, or $\frac{1}{65}$ gr., repeated at intervals of several hours; or, if not for a temporary purpose, this dose should be prescribed twice a day, and gradually increased until its characteristic effects are observed in the pupils and the throat. But, in cases of great functional excitement or disorder, a full grain may be given by the mouth.

HYPERICUM.—St. John's Wort.

Millepertuis, *Casse-diable*, Fr.: *Johanniskraut*, *Hartheu*, G.

Hypericum perforatum, *Lin.* *Nat. Ord.*—Hypericaceæ.

Description.—This plant grows in fields and on roadsides, throughout Europe, Northern Africa, and a considerable portion of Asia, and has been extensively naturalized in North America and in other countries. It has a perennial woody and branching dark-brown root, and a somewhat two-edged stem about 2 feet high. The leaves are opposite, sessile, oblong or linear-oblong, nearly an inch long, obtuse, entire on the margin, and pellucid-punctate. The flowers are in open terminal cymes, deep yellow, nearly an inch broad, and are furnished with numerous stamens clustered in three groups, and with a three-celled ovary. The petals, anthers, leaves, and stem are more or less marked with black dots. When bruised, the herb has a slight balsamic odor; its taste is somewhat resinous, bitter, and slightly astringent.

Constituents.—Buchner (1830) found in the flowers a little tannin, producing a dark-green color with ferric salts, some pectin, and 8 per cent. of a red coloring principle, *hypericum red*, which is soluble in alcohol, ether, volatile oils, and warm olive oil, and dissolves with a green color in ammonia and other alkalies; calcium and lead salts produce yellow precipitates, ferric chloride a yellowish-green one. According to Clamor-Marquart, this coloring matter is a mixture of a red and a yellow principle.

Pharmaceutical Uses.—The fresh flowering tops, digested with olive oil sufficient to cover them, yield a yellowish-red liquid, *oleum hyperici*, which is popularly knows as *red oil*. Linseed oil is sometimes used in place of olive oil.

Allied Plants.—Several other European species of hypericum possess similar properties, and some of our North American species may be equally effective.

HYPERICUM SAROTHRA, *Mich.* (Sarothra gentianoides, *Lin.*, s. Sar. hypericoides, *Nutt.*) has thin, almost thread-like branches, opposite awl-shaped scaly leaves, and minute sessile yellow flowers. It is common in sandy fields in the United States, where it is known as *orange-grass* or *pine-weed*, and is sometimes used like the preceding.

ASCYRUM CRUX-ANDREÆ, *Lin.*, *St. Andrew's cross*, is a decumbent North American herb, with narrow oblong-obovate leaves and solitary flowers, having the four linear-oblong yellow petals arranged in the form of a cross.

Medical Action and Uses.—The aromatic and terebinthinate odor of this plant when it is crushed in the hand, and its resinous and bitter taste, sufficiently account for the vogue which it enjoyed in certain diseases, even from ancient times. It was celebrated by Celsus, Paulus Ægineta, Galen, and Dioscorides, and its vogue only declined when modern science substituted for it medicines whose remedial effects were conceived to be more intelligible. The titles it bore indicate its popular estimation; they were such as these: "St. John's Wort," "The Lord God's Wonder Plant," "The Devil's Scourge," "The Witches' Herb," and many similar. The ancients attributed to it stimulating, drying, cleansing, and cicatrizing virtues, held it to be diuretic and emmenagogue, and a specific remedy for wounds, ulcers, and burns. In the middle ages analogous virtues were ascribed to it as well as curative powers in calculous affections, intestinal worms, and mental disorders. In more recent times it was given for the relief of chronic catarrhs of the lungs, bowels, and urinary passages, and was especially esteemed in the last. It was also used in hot infusion to bring on retarded *menses*. Externally it was applied in the fresh state, bruised, as a discutient for recent *contusions*, and for the relief of local *pains*. Its flowers, immersed in oil in a bottle and hung in the sun for a month or two, give to the oil a dark-red color (red oil), forming one of the most popular applications made to *excoriations*, *wounds*, and *bruises*, both in Europe and in this country. An infusion may be prepared with an ounce of the plant in a pint of hot water.

HYSSOPUS.—HYSSOP.

Hysope, Fr.; *Ysop*, G.

Hyssopus officinalis, *Lin.* *Nat. Ord.*—Labiatæ, Satureieæ.

Description.—Hyssop is an herbaceous perennial, indigenous to Southern Europe, frequently cultivated and sparingly naturalized in the United States. It is about a foot high, with wand-like simple quadrangular branches, and opposite, sessile, linear-lanceolate, entire, and nearly obtuse leaves, which are about an inch long, nearly smooth, and finely punctate on both sides. The purplish-blue flowers are in small clusters, have a 15-ribbed calyx, a two-lipped corolla with a rather short and notched upper lip, and four exserted and divergent stamens. Hyssop has an aromatic, somewhat camphoraceous odor, and a pungent, aromatic, and bitterish taste.

Constituents.—The principal constituent is *oil of hyssop*, of which the fresh herb yields $\frac{1}{4}$ to $\frac{1}{2}$ per cent. It is pale yellow or greenish, limpid, of about the specific gravity 0.94, and freely soluble in alcohol; it contains oxygen, and commences to boil at 142° C. (287.6° F.), the boiling point rising to 180° C.

(356° F.). It has the odor and taste of the herb. The *hyssopin* of Herberger (1829) was found by Trommsdorff to be impure sulphate of calcium.

Allied Plants.—CUNILA MARIANA, *Lin.*, *Dittany*, a North American plant, grows in dry soil, has a thin, purplish, much-branched stem, about 12 inches high, and nearly sessile, ovate, serrate, smooth leaves, which are rounded or subcordate at the base. The pale-purple flowers are in small pedunculate clusters, and have two exserted stamens.

SATUREJA HORTENSIS, *Lin.;* Summer savory, *E.;* Sarriette, *Fr.;* Saturei, Bohnenkraut, *G.*—This South European annual is cultivated as a culinary herb. The stem is about 10 inches high, much branched, roughish pubescent; the leaves are linear-lanceolate or oblong-linear, entire, acute, and tapering into a very short petiole; the cymules are about 3-flowered, with the corolla pale-purplish, and 4 diverging, rather included stamens.

PYCNANTHEMUM LINIFOLIUM, *Pursh*, *Virginia thyme*, has rigid, narrowly linear sessile crowded leaves, which are entire and three-nerved; the flowers are in terminal hemispherical clusters, supported by imbricate rigidly pointed bracts. It has been popularly regarded as useful in hydrophobia, and has been employed in atonic dyspepsia.

PYCN. LANCEOLATUM, *Pursh*, resembles the preceding, but has lanceolate or lance-linear leaves; both have a resinous and bitter taste.

PYCN. INCANUM, *Mich.*, has broader ovate-oblong, hoary, pubescent leaves, and an aromatic mint-like taste. It is known as *mountain mint*, *wild basil*, and in some places as *horse-mint*, and is used like monarda.

Ch. Mohr. (1876) isolated from Pyc. linifolium a tannin which is very similar if not identical with caffeo-tannic acid; volatile oil, resin, bitter principle, etc., were likewise obtained.

Medical Action and Uses.—Anciently hyssop seems to have been used as a cathartic, for we read in Scripture, "I will purge thee with hyssop and thou shalt be clean;" and, if this passage be thought to apply to external cleansing, Pliny says expressly that "mixed with figs it purges, and with honey vomits." He also refers to its external use in phthiriasis. Down to quite a recent period it has been used to improve digestion, particularly in atonic and flatulent *dyspepsia;* and, like other plants which are so employed, and contain an essential oil associated with a bitter and astringent principle, it is found useful in subacute and chronic *bronchitis*, especially in old persons, also in *amenorrhœa*, and externally as a stimulant application to *bruises*, and in muscular *rheumatism.* Its infusion was also used as a gargle in *sore throat* of the diphtheritic form. Hyssop may be given in an infusion made with a drachm of the herb to a pint of water. The essential oil was formerly given in doses of one or two drops.

IBERIS.—IBERIS.

Herbe d'iberis, Fr.; *Iberiskresse*, G.

Lepidium iberis, *Lin.* *Nat. Ord.*—Cruciferæ, Siliculosæ.

Description.—This plant is found from Southern Europe to Siberia; has a branching stem about two feet high; petiolate, pinnatifid or incisely serrate radical leaves about two inches long; smaller linear-lanceolate or linear entire stem-leaves, and minute white flowers in racemose cymes; the fruit is small, ovate, and acute. The plant is smooth and rather glaucous, and has a pungent taste resembling that of allied plants. (See p. 304.)

Constituents.—This plant yields a sulphuretted volatile oil. Leroux (1837) obtained from the flowering tops and seeds an amorphous, bitter principle which he named *lepidin.*

Medical Action and Uses.—This plant was known to the ancients, who employed it as a rubefacient in rheumatic and other local affections. Pliny ascribes the discovery of its virtues to a certain physician named Damocrates. Even in recent times its powdered seeds were incorporated in an ointment for purposes like those above mentioned. Internally it is said to have acted as an irritant, producing nausea and diarrhœa; and to have been useful in bronchitis and dropsy. Its value, if any, is not determined.

ICHTHYOCOLLA, *U. S.*—ISINGLASS.

Colla piscium, P. G.—*Fishglue*, E.; *Colle de poisson*, *Ichthyocolle*, Fr.; *Hausenblase*, *Fischleim*, G.

The swimming bladder of Acipenser huso, *Lin.*, and of other fishes.

Class Pisces. *Ord.* Sturiones.

Origin.—Isinglass is mentioned by the British Pharmacopœia among the articles employed in chemical testing. The kind preferred is that known in commerce as *Russian isinglass*, which is obtained from several sturgeons, species of Acipenser, which inhabit the Caspian and Black Seas and their tributary rivers, and the most important of which are *Ac. huso*, Lin., or *belugo; Ac. Güldenstädtii*, Br. and Ratz., or *osseter; Ac. ruthenus*, Lin., or *sterlet*, and *Ac. stellatus*, Pall., or *sewruga.* It is prepared by cutting the air-bag or swimming-bladder open, washing and soaking it in water, and spreading it upon boards, the outer silvery membrane being turned upward and removed by rubbing. The bladder is then merely dried in sheets, and constitutes *leaf isinglass;* or several are put together and folded before they are completely dry, forming *book isinglass:* or each bladder is rolled up and folded around a few pegs into the form of a horseshoe, heart, or lyre, in which shape it is dried. The latter is the *staple isinglass*, which, according to its dimensions, is again divided into *long* and *short staple.* The kind now most commonly met with in our commerce is the leaf isinglass.

Description.—Russian isinglass is a somewhat horny and tough membranous tissue, which is semi-transparent, of a whitish or pale-yellowish color, pearly appearance, and iridescent; it is best torn in the direction of its fibres, is inodorous, and quite insipid in taste. Immersed in water or diluted alcohol it swells, and dissolves at a somewhat elevated temperature, leaving a flocculent residue not exceeding 2 per cent.; on cooling, its solution with 24 parts of water congeals to a transparent jelly. Isinglass which is discolored or less soluble in water is not adapted for medicinal purposes.

Other Varieties of Isinglass.—The air-bags of most large fishes appear to be adapted for some of the purposes for which isinglass is used in the arts; when they are dried without being split open, they are known as *purse* or *pipe isinglass.*

American isinglass, according to C. T. Carney (1857), is prepared from the sounds of *Gadus merluccius*, Lin., or hake; they are cleansed, soaked in water, passed through rollers, and dried in the form of ribbons or thin and transparent sheets. C. C. Meyer (1873) found the former to leave 30 per cent. and the latter only 18 per cent. of matter insoluble in water; the fresh bladder of a hake weighing 15 ounces left 1 ounce undissolved. Storer states that the swimming bladder of *Otolithus regalis*, Cuv., the weak fish, likewise furnishes some isinglass.

Brazilian isinglass comes from species of the genera Pimelodus and Silurus, the entire sounds being often dried, so as to adhere together (*lump isinglass*), and the lumps are sometimes split open (*honeycomb isinglass*). A false isinglass from Para consisted, according to Pereira (1853), of the ovaries of a fish, probably *Sudas gigas.*

East Indian isinglass is produced from several large fishes, and is met with in the form of purses and of leaves.

Constituents.—Besides membranous matter and some salts, isinglass consists of that variety of gelatin known to chemists as *glutin.* (See Gelatina, page 661.)

Pharmaceutical Uses.—Isinglass forms the basis of *isinglass plaster* and of *court-plaster* (see page 516), and may be employed for similar purposes as gelatin (see page 661). The German Pharmacopœia gives the following process for

EMPLASTRUM ADHÆSIVUM ANGLICUM.—30 grams of isinglass are dissolved in sufficient hot water to obtain a solution weighing 360 grams, one-half of which is spread upon taffeta 104 centimeters long and 42 centimeters wide, each coating being permitted to dry before applying the next. The remaining solution is, meanwhile, mixed with 120 grams of alcohol and 3 grams of glycerin, and this mixture applied in the same manner. The reverse side is then coated with tincture of benzoin, and the plaster finally dried. According to these directions 1 gram of isinglass is made to cover 21 square inches.

Medical Action and Uses.—Isinglass was anciently applied as a protective to the skin when it was abraded or affected with eruptions. It is emollient and nutritive, and forms a valuable addition to boiled milk, or to farinacea prepared with milk, in treating the chronic bowel complaints of children. In court-plaster it is used for its adhesive qualities.

IGNATIA, *U. S.*

Semen Ignatiæ, Faba Ignatii.—Ignatia, Bean of St. Ignatius, E.; *Fève de Saint-Ignace, Fève igasurique,* Fr.; *Ignazbohnen,* G.

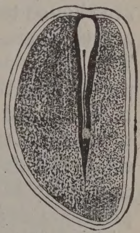
The seed of Strychnos Ignatia, *Lindley* (Str. Ignatii, *Bergius*, s. Str. philippensis, *Blanco*, s. Ignatiana philippinica, *Lour.*, s. Ignatia amara, *Lin. f.*).

Nat. Ord.—Loganiaceæ.

Origin.—This is a large climbing shrub, indigenous to the Philippine Islands and naturalized in Cochin China, with opposite ovate leaves, and an oblong or subglobular berry-like fruit, having a brittle pericarp, and containing about 24 seeds imbedded in a bitter pulp.

Description.—The seeds are from 1 to 1¼ inch long, oblong, ovate or roundish ovate in shape, by mutual pressure irregularly angular; the hilum is on one of the edges in a small depression, and the surface of the seeds is of a dull reddish-gray, or brownish, when old even blackish color, and granular, or partly covered by gray or light brown silky hairs. Ignatia consists of a very hard horny albumen, which is of the shape of the seeds, and translucent at the edges, and surrounds an irregular cavity. The embryo projects into this cavity and consists of a rather long radicle and oblong ovate, acute cotyledons. The seeds break under the hammer with a granular and irregular fracture, and soften after prolonged digestion. They are inodorous, and have a very persistent bitter taste.

Fig. 89.



Ignatia.—Vertical section of seed.

Constituents.—Pelletier and Caventou (1819), found the seeds to contain the same constituents, though in different proportions, as nux vomica; they stated the yield of strychnia (still containing brucia) to be 1.4 per cent. Geiseler (1837) likewise found 1.5 per cent. of this alkaloid. F. F. Mayer (1863), on assaying ignatia with his solution, obtained from two troyounces of the seeds 4.5 grains of strychnia and 13.73 grains of brucia, which correspond to 0.52 per cent. of the former, and 1.43 per cent. of the latter.

Off. Prep.—Extractum ignatiæ, *U. S.*

Medical Action and Uses.—The action and uses of ignatia are identical with those of nux vomica.

ILEX.—HOLLY.

Houx, Fr.; *Stechpalme*, *Christdorn*, G.

The leaves of different species of Ilex. *Nat. Ord.*—Aquifoliaceæ.

Origin and Description. ILEX OPACA, *Ait.*, *American holly.*—It is indigenous to the United States, and is either shrubby, or a tree 30 or 40 feet high. The leaves are petiolate, coriaceous and evergreen, about two inches long, oval in shape, and with a wavy-toothed margin, the teeth being furnished with rigid and sharp spines. They are without odor, and have a mucilaginous, bitterish and astringent taste.

ILEX AQUIFOLIUM, *Lin.*—The *European holly* is very nearly related to the preceding. The leaves differ in being rather ovate, dark green and glossy on the upper surface.

ILEX CASSINE, *Lin.*, known as *yaupon*, *youpon* or *cassena.*—It grows in the United States from Virginia southward. The leaves are shortly petiolate, about 1 inch long, coriaceous, varying in shape between lance-ovate, ovate and oblong, crenate on the margin, smooth, dark green and glossy above, and paler beneath. They are inodorous, and have an astringent and bitterish taste.

The following two species are likewise known as *cassena* in the Southern States:—

ILEX DAHOON, *Walt.*, has leaves about 2 inches long, which are oblong or oblanceolate, with the margin revolute or entire, or sharply serrate towards the apex.

ILEX MYRTIFOLIA, *Walt.*—The leaves are linear-lanceolate or linear-oblong, 1 inch long, entire on the margin, or furnished with a few sharp teeth.

The fruit of these species is a red drupe, usually containing four one-seeded ribbed or grooved nutlets.

ILEX PARAGUAYENSIS, *St. Hil.*, is a small tree indigenous to Brazil and the Argentine Republic. The leaves are oblong or lanceolate, wedge-shaped at the base, rather obtuse at the apex, and with distant teeth on the margin. They furnish the *yerba maté* or *Paraguay tea*, which is prepared as follows: The small branches with the leaves are placed in the *tatacúa*, a plot of earth about 6 feet square, surrounded by fire, where they undergo their first roasting. They are thence taken to the *barbacúa*, which is a grating underneath which burns a fire, where they are somewhat torrefied, to develop the aromatic principle. The leaves are subsequently reduced to powder in a sort of mortar, formed of pits dug in the earth, and well rammed. More recently suitable furnaces have been erected for drying and torrefaction, and mills are used for powdering.

Constituents.—The leaves of the European holly were examined by Lassaigne (1822), Déleschamps (1832), Lebourdais (1841), Moldenhauer (1857), and Bennemann (1858). The four first-named investigators obtained the bitter principle as a more or less colored amorphous mass; Bennemann in the form of feathery crystals, too small in quantity for further investigation. Déleschamp's *ilicin* was *not*, but Moldenhauer's and Bennemann's *was* precipitated by subacetate of lead; Lebourdais' ilicin was absorbed from the decoction by animal charcoal, and extracted from it by boiling alcohol. D. P. Pancoast's (1856) ilicin was obtained by Lebourdais' process from the fruit of the American holly, and is described as being in minute needles; the same process applied to the leaves yielded an amorphous green mass.

Moldenhauer isolated *ilixanthin*, $C_{17}H_{22}O_{11}$, the yellow coloring matter of the leaves, in the form of straw-yellow needles, which are soluble in alcohol and boiling water, but insoluble in ether. *Ilicic acid* is syrupy; its barium salt is amorphous, the calcium salt crystallizes in scales.

The yaupon contains 0.122 per cent. of *caffeina*, 2.409 per cent. of tannin, 4 per cent. of ash, besides wax, resin, etc., according to the analysis of H. M. Smith (1872). Caffeina was also found in maté by Stenhouse (1843), who regards the tannin as differing somewhat from caffeo-tannic acid. Rochleder, on the contrary, considers the tannin from the two sources as identical. Alonzo Robbins (1878) examined seven samples of maté, and found the caffeina to vary between 0.2 and 1.6 per cent., and the tannin between 10 and 16 per cent.; the samples containing the largest amount of caffeina yielded the least tannin, and *vice versa*.

Medical Action and Uses.—According to Barbier, holly leaves and their preparations produce a sense of heat and oppression in the stomach, with some nausea, followed by colic without diarrhœa. The berries vomit and purge, and at least one case is recorded of their proving fatal to a child. The leaves, being bitter, were naturally employed for the cure of *intermittent fever*, and a formal inquest upon their virtues having been held upon them by the Institute of France, its chairman reported that their efficiency was real, although it was very slow in exhibiting itself. He was probably unacquainted with the fact that intermittent fever patients removed to a hospital generally recover without medicinal treatment. Moreover, subsequent clinical observations by competent physicians proved that the curative power of the medicine in this disease is absolutely null. The leaves have been used in *rheumatism*, internally and topically, and the berries as cathartics in *dropsy*. An American species, *I. opaca*, is demulcent, and is used in decoction to palliate cough and promote expectoration.

ILLICIUM.—STAR ANISE.

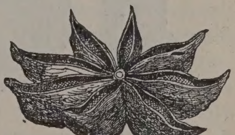
Fructus (Semen) anisi stellati, Semen badiani.—*Badiane, Anise étoilé*, Fr.; *Sternanis*, G.

The fruit of Illicium anisatum, *Lour.*, s. Ill. religiosum, *Siebold.* Bentley and Trimen, Med. Plants, 10.

Origin.—This is a small tree with evergreen lanceolate entire pellucid punctate leaves and greenish-yellow polypetalous flowers. It is indigenous to and cultivated in Eastern Asia, and planted near the temples in Japan. During the year 1866–1867, there were imported into the United States 17,307 pounds of star anise.

Description.—Star anise consists of about 8 boat-shaped follicles which are horizontally arranged in one circle around a short axis. The follicles are somewhat beaked, wrinkled, of a brown color externally, internally smooth, red-brown and glossy, and on the upper margin usually split open. Each carpel has a single seed, which is oval, flattened, oblique at the base, smooth and of a polished brown color, and contains a large oily albumen inclosing the small embryo. Star anise yields about 78 per cent. of capsular integuments, which have a very agreeable anise-like odor and a sweetish aromatic taste. The seeds weigh about 22 per cent., are but slightly aromatic, and have an oily taste.

Fig. 90.



Star Anise.

Constituents.—The fruit and seeds were separately examined by Meissner (1818), who obtained from the former 5.3 per cent. of volatile oil, 2.8 of fat, 10.7 of resin, etc.; the fruit seems also to contain a little tannin, mucilage, and pectin. The seeds were found by Meissner to yield only 1.8 per cent. of volatile oil and 2.6 per cent. of resin, but about 20 per cent. of fixed oil. The volatile oil is chemically identical with that of Pimpinella anisum (see Oleum anisi).

Allied Plants.—Illicium floridanum, *Ellis*, and Ill. parviflorum, *Mich.*, two shrubs, indigenous to Florida and adjacent States, are strongly aromatic and anise-like. The fruit of I. floridanum and of I. parviflorum resembles the preceding, but the carpels are 12 or 15 in number.

Medical Action and Uses.—Star aniseed has the same qualities as the officinal anise, and in the East its seeds and oil are used for the same purposes, viz., as carminative, anodyne, stimulant, and diuretic, and as a condiment for vegetable food. Externally, they are there applied to allay local pains, such as *colic*, *rheumatism*, *earache*, etc. In Germany, they are employed in a similar manner, and also for the relief of *bronchitis*. The native species, I. floridanum, is aromatic in its leaves, bark, and seeds; the bark has been suggested as a substitute for cascarilla, and the seeds for those of anise. The root of I. parviflorum is said to resemble that of sassafras in its properties.

IMPERATORIA.—MASTERWORT.

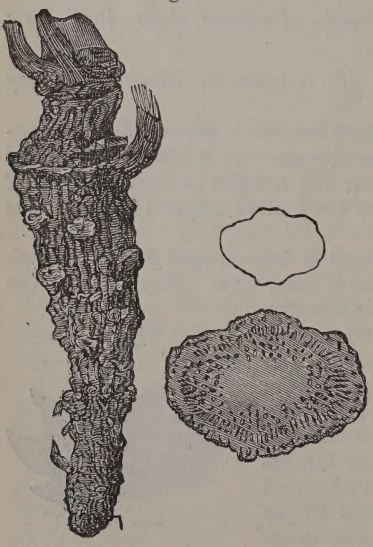
Impératoire, Fr.; *Meisterwurz*, *Kaiserwurz*, G.

The root-stock of Imperatoria ostruthium, *Lin.* *Nat. Ord.*—Umbelliferæ, Orthospermæ.

Origin.—Masterwort is indigenous to the mountainous regions of Southern and Central Europe, grows 2 or 3 feet high, and has large umbels of many white or reddish flowers. The root-stocks are produced at the termination of thin rhizomes, which are about 6 inches long.

Description.—The root-stock is 2 or 3 inches long, of the thickness of a finger, somewhat conical, and slightly flattened. Externally, it is dark brownish-gray, wrinkled, with warty protuberances or scars, and finely annulate. Internally, it is brownish-white, and exhibits upon the transverse section a thin bark and a large central pith, both containing many brown-yellow resin-cells; the wood bundles are small, forming a loose circle. Masterwort has a strong balsamic odor and an aromatic pungent and bitter taste. It has been noticed by Holmes (1877) as an adulteration of aconite root.

Fig. 91.



Imperatoria ostruthium, *Lin.*—Root-stock, natural size; and transverse section, natural size, and magnified.

Constituents.—Masterwort contains about $\frac{3}{4}$ per cent. of volatile oil, which, according to Hirzel (1849), is a mixture of several hydrates of a hydrocarbon, $C_{10}H_{16}$. Wackenroder (1831) obtained colorless shining crystals of *imperatorin*, $C_{12}H_{12}O_3$, which, in alcoholic solution only, have a pungent taste. Schlatter (1833) obtained *peucedanin* from the root of Peucedanum officinale, *Lin.*, which was afterwards proved by R. Wagner to be identical with imperatorin. Both principles, when boiled with an alcoholic solution of potassa, are resolved into *angelic acid* and *oreoselin*, $C_{14}H_{12}O_4$. The latter body may also be obtained from *athamantin*, $C_{24}H_{30}O_7$, which was discovered by Winckler (1842) in the root of Athamanta (Peucedanum, *Mœnch*) oreoselinum, *Lin.* Athamantin resembles imperatorin, unites with dry hydrochloric acid, and, on boiling this compound with alcohol, is split into *valerianic acid* and *oreoselon*, $C_{14}H_{10}O_3$, which crystallizes in needles, and, on being boiled with water and an acid, yields the crystalline oreoselin.

Medical Action and Uses.—The acrid and aromatic taste of this plant, and its odor resembling that of angelica, depend upon its essential oil; and to the stimulating operation of this oil nearly all the remedial virtues of the medicine are due. It is but little used at the present day, but it was formerly employed in various conditions of local or general debility. Among these were the *typhoid state* of fevers and inflammations, *intermittent fever*, *delirium tremens*, and some forms of dropsy; atonic *dyspepsia*, *flatulent colic*, *hysteria*, and *asthma;* and locally it was used as a masticatory to relieve *toothache* and *paralysis* of the tongue or palate, and as a stimulant of unhealthy *ulcers.*

INDIGO.—Indigo.

Indicum, Pigmentum indicum.—Indigo, Fr., G.

A blue dye-stuff extracted from different species of Indigofera. Bentley and Trimen, Med. Plants, 72.

Nat. Ord.—Leguminosæ, Papilionaceæ.

Origin.—The genus consists of herbaceous or suffruticose plants, which are indigenous to and cultivated in tropical and subtropical countries. The most important species are Indigofera tinctoria, *Lin.* (s. I. indica, *Lam.*), I. anil, *Lin.*, and I. argentea, *Lin.* (s. I. glauca, *Lam.*, I. cœrulea, *Roxb.*). The genus *Baptisia* appears to yield a similar coloring matter. Indigo is also obtained from Isatis tinctoria, *Lin.*, *Nat. Ord.* Cruciferæ, the *woad* indigenous to Europe, and from Polygonum tinctorium, *Lin.*, *Nat. Ord.* Polygonaceæ, a native of China.

Preparation.—The plants are immersed in water until fermentation has set in, whereby the chromogene is dissolved. When the liquid has assumed a sherry color, it is drawn off and briskly stirred so as to bring it freely into contact with air. As the chromogene becomes oxidized, the newly-formed coloring matter, which is insoluble in water, subsides. The supernatant liquid is then decanted and the precipitate collected, pressed, and dried. Between 1 and 1½ million pounds of indigo are annually imported into the United States.

Properties.—Indigo is met with in hard but brittle lumps or cubical cakes, which are inodorous, tasteless, and of a deep blue color, assuming a coppery hue when scratched or rubbed with a hard body. It is insoluble in the ordinary solvents, dissolves freely in concentrated sulphuric acid, and, when rapidly heated, sublimes partly in purple-colored vapors, which condense into copper-colored needles. The color of indigo is altered by oxidizing and deoxidizing agents.

Constituents.—Indigo contains variable quantities of inorganic substances; when of good quality it yields about 7 per cent. of ash. It contains the proteid *indigo-gluten*, which is soluble in warm diluted acids, and the coloring principles *indigo-brown*, soluble in caustic alkalies, and *indigo-red* or *indigo-resin*, which is taken up by boiling alcohol after the indigo has been previously exhausted with dilute acids and alkalies. But the most important principle is *indigo-blue* or *indigotin*, of which good indigo contains between 50 and 60 per cent., and which is not contained in the plants, but is formed from a colorless syrupy bitterish compound called *indican*, $C_{26}H_{33}NO_{18}$. During the treatment described above, indican is split into a saccharine body, *indiglucin*, and indigotin,

C_8H_5NO. On mixing 2 or 3 parts of finely powdered indigo, 6 parts of slaked lime, 4 parts of ferrous sulphate, and 450 parts of boiling water, the blue color disappears, and the yellow solution contains *indigo-white*, C_8H_6NO, which may be obtained as a white crystalline powder on adding the clear solution to an excess of boiled dilute hydrochloric acid, with the precaution to avoid all contact with the air; if access of air be permitted during the latter part of this process, indigotin is regenerated and deposited in the form of a deep blue powder. By oxidation of indigotin with nitric acid, *isatin*, $C_8H_5NO_2$, is obtained, forming yellowish-red shining prisms, which are soluble in alcohol, hot water, and alkalies, and, on distillation with potassa, yield *anilina*.

Soluble indigo, or *sulphate of indigo*, is prepared by gradually adding 1 part of powdered indigo to 5 parts of Nordhausen sulphuric acid, or 8 parts of oil of vitriol, and preventing a rise of temperature by immersing the vessel in cold water. In the course of 2 or 3 days it becomes a dark blue pasty mass, the solution of which in about two parts of water is *liquid blue*. This compound contains *sulphindigotic*, or *sulphocœrulic acid*, $HC_8H_4NO.SO_3$, which is obtained pure by transferring it from its dilute solution to wool, and dissolving it from the latter by means of a weak alkali. Its salts are amorphous; those with potassium and sodium are sold in commerce as *indigo-carmine*, and are usually obtained by adding a potassium or sodium salt to a solution of sulphate of indigo, washing the precipitate with a solution of the same salt, and expressing; the product is soluble in pure water.

The *valuation of indigo* is based upon determining approximately the amount of indigotin contained in it, by the process given above, or by adding chlorine ($KClO_3$ and HCl) to finely powdered indigo until the blue color has been destroyed. The richer it is in indigotin, the larger will be the amount of chlorine necessary to effect decolorization.

Pharmaceutical Uses.—Besides its uses in the arts for dyeing, a solution of indigo is employed as a test for determining the presence of nitric acid, chlorine, etc.

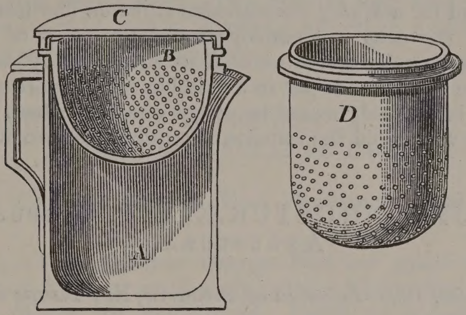
Medical Action and Uses.—During the experiments made many years ago with indigo in the treatment of *epilepsy*, it was given in very large doses, and, as a consequence, deranged the digestive organs, causing vomiting and purging, with debility, and in some instances the urine and sweat acquired a bluish color. There is not the slightest ground for believing that it exhibits curative virtues in epilepsy or in any other disease.

INFUSA, *U. S.*, *Br.*

Infusions, E., Fr.; *Tisanes*, Fr.; *Infusionen*, *Aufgüsse*, G.

Infusions are aqueous solutions of the soluble principles of vegetable or animal drugs obtained by maceration or digestion in hot or cold water, and differ from decoctions only in the lower degree of heat employed in their preparation. Substances containing volatile or other principles which would be dissipated or injured by boiling, are particularly adapted for this purpose, and it will be observed that the majority of the officinal infusions are made with drugs, the activity of which depends wholly or in part upon a volatile constituent. Except in a few cases in which percolation is directed, infusions are prepared by pouring boiling or cold water upon the material, and allowing them to remain in contact for the proper length of time, at the expiration of which the solution is poured upon a strainer, and the solid material expressed, to recover the liquid absorbed by it. A convenient apparatus well adapted for making these preparations is Squire's infusion pot; this consists of a jar A, with a projecting ledge near the top, which supports a strainer, B or D, containing the material to be exhausted; the jar is closed by a well-fitting cover, C. The advantages of this contrivance are, that the material is exhausted by circulatory displacement, the liquid as it becomes charged with the soluble ingredients descending to the bottom, giving place to fresh portions of less saturated menstruum; and that no further straining is required, should care have been taken not to use too fine a powder.

Fig. 92.



Squire's Infusion Pot.

The drugs are best adapted for exhaustion with water if cut into thin slices by a suitable knife, so that they may be easily permeated by the liquid; when cutting is inadmissible, they should be bruised to a coarse powder. Ligneous drugs, however, should be in a fine or moderately fine powder, which is also best adapted for most of those which may be made by percolation.

The time directed for the maceration with boiling water is, in the U. S. Pharmacopœia, usually two hours, and in the British Pharmacopœia a quarter or half hour, which is in most cases sufficient.

The strength of the infusions of the British Pharmacopœia is usually such that the virtues of one part of the drug are represented by 20 or 40 parts of the infusion; the majority of the infusions of the U. S. Pharmacopœia are made approximately in the proportion of 1 to 15 or 30 by weight. The *tisanes* of the French Codex are weaker than either of the preceding, and generally in the proportion of 1 to 100, or occasionally 200.

Infusions are not intended to be kept except for a very limited period. Exposed to air, as they necessarily must be in the sick chamber, through the vial containing them being opened from time to time, decomposition must ensue after a day or two, and may be retarded somewhat only by keeping the vessel in a cool place, or, better still, on ice. When desirable to have a larger quantity prepared, the liquid may be preserved by *Appert's method;* it is put into convenient sized vials, which are heated in a water-bath gradually to the boiling point, and stopped well at that temperature. However, considering that infusions are rarely made by the pharmacist, but are usually prepared by the attendants of the patient, and may be frequently made as required, there is little necessity for such a course, or for any of the various contrivances that have been proposed for obviating fermentation and other changes in infusions. But for the physician it may be useful to know that most of the infusions may be prepared in a more concentrated form, or reduced in volume by evaporation at a moderate heat, and then be kept unaltered for a considerable time by the addition of one-third their volume of alcohol. Dissolving half a grain of salicylic acid in each fluidounce of the infusion will have a similar preservative effect.

Nearly all the infusions will yield precipitates or become discolored with the salts of iron, lead, mercury, silver, and other heavy metals, and are therefore incompatible with them.

The Pharmacopœia would, perhaps, not be less useful to the physician and the pharmacist if all infusions were omitted except those which require some special manipulation, or which, from their containing a sufficient amount of alcohol, are permanent for a reasonable length of time. The German Pharmacopœia recognizes by formula only one infusion (Inf. sennæ comp.), but gives the following general directions: "When infusions are ordered without giving the quantity of the drug to be used, they are made so that from one part of the drug ten parts of liquid are obtained. For a *concentrated infusion* (infusum concentratum), one and a half parts, and for a *highly concentrated infusion* (infusum concentratissimum) two parts of the drug are employed, and ten parts of liquid obtained. The quantity of medicinally active substances should always be determined by the physician. The substance is put in a suitable vessel, boiling water is poured upon it, the vessel is covered, heated by means of a steam-bath for five minutes, then set aside, and when cold the infusion is strained with expression."

INFUSUM ANGUSTURÆ, *U. S.*—INFUSION OF ANGUSTURA.

Infusum cuspariæ, Br.—*Infusion of cusparia*, E.; *Tisane d'angusture*, Fr.; *Angustura-Infusion*, G.

Preparation.—Take of Angustura in moderately coarse powder half a troyounce; Water a sufficient quantity. Moisten the powder with two fluidrachms of water, pack it firmly in a conical percolator, and gradually pour water upon it until the filtered liquid measures a pint. Or, macerate the angustura in a pint of boiling water for two hours, in a covered vessel, and strain. *U. S.*

Take of Cusparia Bark in coarse powder one-half ounce; Distilled Water, at 120° F., ten fluidounces. Infuse in a covered vessel for two hours, and strain. *Br.*

Medical Uses.—Besides being used in cases of digestive debility, it is also employed, like the infusions of cinchona, as an adjuvant to quinia, or as a substitute for it in cases of mild intermittent fever. Its use is limited by the liability of the bark to be mixed with that of false angustura bark. The *dose* is from one to two fluidounces.

INFUSUM ANTHEMIDIS, *U. S.*, *Br.*—INFUSION OF CHAMOMILE.

Infusum chamomillæ romanæ.—*Tisane de chamomille romaine*, Fr.; *Römisch-Kamillenthee*, G.

Preparation.—Take of Chamomile half a troyounce; Boiling Water a pint. Macerate for ten minutes, in a covered vessel, and strain. *U. S.*

Take of Chamomile Flowers one-half ounce; Boiling Distilled Water ten fluidounces. Infuse in a covered vessel for fifteen minutes, and strain. *Br.*

Medical Uses.—The *dose* of this infusion is about a wineglassful before meals; it is more apt to agree with the stomach when made with cold water. The infusion, when warm, is an efficient and gentle emetic.

INFUSUM AURANTII, *Br.*—INFUSION OF ORANGE PEEL.

Tisane d'écorce d'orange, Fr.; *Pomeranzenschalen-Aufguss*, G.

Preparation.—Take of Bitter Orange Peel cut small one-half ounce; Boiling Distilled Water ten fluidounces. Infuse in a covered vessel for fifteen minutes, and strain. *Br.*

Medical Action and Uses.—This infusion may be prescribed to allay pain and flatulence in *colic*, and as a vehicle for other medicines, particularly magnesia. *Dose*, one or two fluidounces.

INFUSUM AURANTII COMPOSITUM, *Br.*—COMPOUND INFUSION OF ORANGE PEEL.

Tisane d'écorce d'orange composée, Fr.; *Pomeranzen- und Citronenschalen-Aufguss*, G.

Preparation.—Take of Bitter Orange Peel cut small one-quarter of an ounce; Fresh Lemon Peel cut small sixty grains; Cloves bruised thirty grains; Boiling Distilled Water ten fluidounces. Infuse in a covered vessel for a quarter of an hour, and strain. *Br.*

Medical Action and Uses.—The compound infusion of orange peel is a grateful carminative, appropriate in *flatulence*, and also in slight *diarrhœa* caused by indigestion. *Dose*, one or two fluidounces.

INFUSUM BUCHU, *U. S.*, *Br.*—INFUSION OF BUCHU.

Infusum diosmæ s. barosmæ.—*Tisane de bucco*, Fr.; *Buchuaufguss*, G.

Preparation.—Take of Buchu a troyounce; Boiling Water a pint. Macerate for two hours, in a covered vessel, and strain. *U. S.*

Take of Buchu Leaves bruised one-half ounce; Boiling Distilled Water ten fluidounces. Infuse in a covered vessel for an hour, and strain. *Br.*

Medical Uses.—This preparation contains all the virtues of buchu, and is preferable to more concentrated forms of the medicine. *Dose*, one or two fluidounces. It is usual to make an infusion with equal proportions of buchu and uva ursi.

INFUSUM CALUMBÆ, *U. S.*, *Br.*—INFUSION OF COLUMBO.

Infusion of calumba, E.; *Tisane de colombo*, Fr.; *Kolombo-Infusion*, G.

Preparation.—Take of Columbo in moderately coarse powder half a troyounce; Water a sufficient quantity. Moisten the powder with two fluidrachms of water, pack it firmly in a conical percolator, and gradually pour water upon it until the filtered liquid measures a pint. Heat the filtrate to the boiling point, and strain when cold. Or, macerate the Columbo in a pint of Boiling Water for two hours, in a covered vessel, and strain. *U. S.*

Take of Calumba Root cut small half an ounce; Cold Distilled Water ten fluidounces. Macerate in a covered vessel for one hour, and strain. *Br.*

The infusion made by the second process of the United States Pharmacopœia is much more mucilaginous and unsightly than those made with cold water either by maceration or percolation, as directed by the other formulas.

Medical Uses.—This is probably the most useful preparation of columbo, if made with due precautions. *Dose*, a wineglassful before meals.

INFUSUM CAPSICI, *U. S.*—INFUSION OF CAPSICUM.

Tisane de capsique, Fr.; *Spanischpfeffer-Infusion*, G.

Preparation.—Take of Capiscum in coarse powder half a troyounce; Boiling Water a pint. Macerate for two hours in a covered vessel, and strain. *U. S.*

Medical Uses.—Infusion of capsicum is used almost exclusively as a gargle in the treatment of pseudo-membranous and gangrenous affections of the *throat*, including these conditions in *scarlet fever*, and of the forming stage of simple inflammation of the same part. No other local treatment is more efficient, and none, perhaps, as much so. When patients are unable to use the infusion as a gargle, it may be applied with a mop. The following preparation has had a great reputation in malignant sorethroat: Take two tablespoonfuls of capsicum and the same quantity of fine salt, beat them into a paste with a little water, and add half a pint of boiling water. Strain off the liquor, when cold, and add to it half a pint of very sharp vinegar. Of this the dose for an adult is a tablespoonful every half hour. Except when the throat is covered with false membrane and with sloughs, the acrimony of this preparation is not easily borne.

INFUSUM CARYOPHYLLI, *U. S.*, *Br.*—INFUSION OF CLOVES.

Tisane de girofle, Fr.; *Gewürznelken-Infusion*, G.

Preparation.—Take of Cloves bruised one hundred and twenty grains; Boiling Water a pint. Macerate for two hours in a covered vessel, and strain. *U. S.*

Take of Cloves bruised a quarter of an ounce; Boiling Distilled Water ten fluidounces. Macerate in a covered vessel for one hour, and strain. *Br.*

Medical Uses.—Infusion of cloves is used to allay flatulent colic, and nausea from exhaustion. *Dose*, a tablespoonful.

INFUSUM CASCARILLÆ, *U. S.*, *Br.*—INFUSION OF CASCARILLA.

Tisane de cascarille, Fr.; *Kaskarilla-Aufguss*, G.

Preparation.—Take of Cascarilla in moderately coarse powder a troyounce; Water a sufficient quantity. Moisten the powder with half a fluidounce of water, pack it firmly in a conical percolator, and gradually pour water upon it until the filtered liquid measures a pint. Or, macerate the Cascarilla in a pint of Boiling Water for two hours in a covered vessel, and strain. *U. S.*

Take of Cascarilla Bark in coarse powder one ounce; Boiling Distilled Water ten fluidounces. Infuse in a covered vessel for one hour, and strain. *Br.*

Medical Uses.—Cascarilla is best administered in this form. It may be given in doses of two fluidounces two or three times a day.

INFUSUM CATECHU COMPOSITUM, *U. S.*—COMPOUND INFUSION OF CATECHU.

Infusum catechu, Br.—*Infusion of catechu*, E.; *Tisane de cachou composée*, Fr.; *Catechuaufguss mit Zimmt*, G.

Preparation.—Take of Catechu in fine powder half a troyounce; Cinnamon in moderately fine powder sixty grains; Boiling Water a pint. Macerate for an hour, in a covered vessel, and strain. *U. S.*

Take of Pale Catechu in coarse powder one hundred and sixty grains; Cinnamon Bark bruised thirty grains; Boiling Distilled Water ten fluidounces. Infuse in a covered vessel for half an hour, and strain. *Br.*

Medical Uses.—The addition of cinnamon to catechu in this preparation increases its astringency, and renders it stimulant and anodyne at the same time. It is a convenient remedy for diarrhœa with flatulent colic, provided that the bowels are free from irritating ingesta. *Dose*, from one to three fluidounces.

INFUSUM CHIRATÆ, *Br.*—INFUSION OF CHIRETTA.

Tisane de chirette, Fr.; *Chiretta-Thee*, G.

Preparation.—Take of Chiretta cut small a quarter of an ounce; Distilled Water at 120° F. ten ounces. Infuse in a covered vessel for half an hour, and strain. *Br.*

Medical Uses.—This infusion resembles that of quassia in its qualities, and may be used where simple bitters are needed, in the *dose* of two or three fluidounces.

INFUSUM CINCHONÆ FLAVÆ, *U. S.*, *Br.*—INFUSION OF YELLOW CINCHONA.

Infusion of calisaya bark, E.; *Tisane de quinquina jaune*, Fr.; *Kalisayarindenaufguss*, G.

Preparation.—Take of Yellow Cinchona in moderately fine powder a troyounce; Aromatic Sulphuric Acid a fluidrachm; Water a sufficient quantity. Mix the acid with a pint of water. Then moisten the powder with half a fluidounce of the mixture, and, having packed it firmly in a conical glass percolator, gradually pour upon it the remainder of the mixture, and afterwards water, until the filtered liquid measures a pint. *U. S.*

Take of Yellow Cinchona Bark in coarse powder half an ounce; Boiling Distilled Water ten fluidounces. Infuse in a covered vessel for two hours, and strain. *Br.*

The first process, if well conducted, obtains all the alkaloids of the bark in a soluble condition, and is, in point of fact, simply a solution of the sulphates of these alkaloids. The second process will yield preparations very different in appearance and strength if the infusion is strained at a higher or lower temperature; in the former case it will be similar to a decoction of the bark, and become turbid on cooling, while in the latter case it will be clear, but contain only that portion of the cinchona alkaloids which in the natural combination are soluble in cold water. But to extract the bark with cold water alone, would require a longer maceration or slow percolation of it in moderately fine powder.

Medical Uses.—The infusions of cinchona are used only as tonics and not as antiperiodics, and may be prescribed in the *dose* of two fluidounces three times a day.

INFUSUM CINCHONÆ RUBRÆ, *U.S.*—INFUSION OF RED CINCHONA.

Tisane de quinquina rouge, Fr.; *Rothe China-Infusion*, G.

Preparation.—Take of Red Cinchona in moderately fine powder a troyounce; Aromatic Sulphuric Acid a fluidrachm; Water a sufficient quantity. Mix the acid with a pint of water. Then moisten the powder with half a fluidounce of the mixture, and, having packed it firmly in a conical glass percolator, gradually pour upon it the remainder of the mixture, and afterwards water, until the filtered liquid measures a pint. *U. S.*

It contains the alkaloids of the red cinchona bark dissolved in the form of sulphates.

Medical Uses.—Its uses are the same as those of the infusion of yellow cinchona.

INFUSUM CUSPARIÆ, *Br.* See INFUSUM ANGUSTURÆ.

INFUSUM CUSSO, *Br.*—INFUSION OF KOUSSO.

Tisane de cousso, Fr.; *Kossotrank*, G.

Preparation.—Take of Kousso in coarse powder half an ounce; Boiling Distilled Water eight fluidounces. Infuse in a covered vessel, for fifteen minutes, without straining. *Br.*

Medical Uses.—Following the Abyssinian mode of administering this vermifuge, the coarsely powdered flowers are taken along with the water in which they are infused. The eight fluidounces should be divided into two portions, and taken at intervals of an hour in the morning, fasting.

INFUSUM DIGITALIS, *U. S.*, *Br.*—INFUSION OF DIGITALIS.

Tisane de digitale, Fr.; *Fingerhutaufguss*, G.

Preparation.—Take of Digitalis in coarse powder sixty grains; Tincture of Cinnamon a fluidounce; Boiling Water half a pint. Macerate the digitalis in the water for two hours, in a covered vessel, and strain; then add the tincture of cinnamon and mix. *U. S.*

Take of Digitalis Leaves dried thirty grains; Boiling Distilled Water ten fluidounces. Infuse in a covered vessel for one hour, and strain. *Br.*

The bitter taste of digitalis is masked in the first preparation by the cinnamon, and the small quantity of alcohol and oil of cinnamon will preserve the infusion for several days, before a precipitate makes its appearance, which probably contains a portion of the digitalin in combination with the tannin of the cinnamon. D. E. Prall (1878), however, did not succeed in isolating digitalin from the precipitate.

Medical Uses.—The infusion is probably the most certain diuretic preparation of digitalis. In the treatment of *dropsy*, it should be steadily continued until it begins to act either upon the kidneys, the stomach, the pulse, or the bowels. Then, however, it should be at once discontinued, or its dose greatly lessened. Its physiological effects, it should be remembered, continue for several days after the medicine is suspended, and its diuretic action occurs most readily during a state of rest. *Dose*, from half an ounce to an ounce two or three times a day. A compound vinous infusion is a more efficient diuretic than the simpler officinal preparation, thus: White wine seven hundred and fifty parts; Juniper berries bruised fifty parts; Digitalis ten parts; Squill five parts. Macerate for four days, and add acetate of potassa fifteen parts. *Dose*, a tablespoonful three times a day.

INFUSUM DULCAMARÆ, *Br.*—INFUSION OF DULCAMARA.

Tisane de douce-amère, Fr.; *Bittersüssaufguss*, G.

Preparation.—Take of Dulcamara bruised one ounce; Boiling Distilled Water ten fluidounces. Infuse in a covered vessel for one hour, and strain. *Br.*

Medical Uses.—The infusion is probably the most efficient preparation of dulcamara. Its very dilution renders it more operative. *Dose*, from one to two fluidounces.

INFUSUM ERGOTÆ, *Br.*—INFUSION OF ERGOT.

Tisane de seigle ergoté, Fr.; *Mutterkornaufguss*, G.

Preparation.—Take of Ergot in coarse powder one-quarter ounce; Boiling Distilled Water ten fluidounces. Infuse in a covered vessel for half a hour, and strain. *Br.*

Medical Uses.—The *dose* of this preparation for a woman in *labor* is one to two fluidounces. Each fluidounce contains about ten grains of ergot.

INFUSUM EUPATORII, *U. S.*—INFUSION OF THOROUGHWORT.

Tisane d'herbe à fièvre, Fr.; *Eupatorium-Aufguss*, G.

Preparation.—Take of Thoroughwort a troyounce; Boiling Water a pint. Macerate for two hours in a covered vessel, and strain. *U. S.*

Medical Uses.—This infusion is used cold as a tonic and antiperiodic, in the *dose* of one or two fluidounces two or three times a day. As a diaphoretic, it is administered hot in doses of a fluidounce or two every half hour until nausea occurs, or the proposed effect is induced. As an emetic, it is given warm in the dose of half a pint, repeated if necessary.

INFUSUM GENTIANÆ COMPOSITUM, *U. S.*—COMPOUND INFUSION OF GENTIAN.

Mistura gentianæ, Br.; *Gentian mixture*, E.; *Tisane de gentiane composée*, Fr.; *Enzianaufguss*, G.

Preparation.—Take of Gentian in moderately coarse powder half a troyounce; Bitter Orange Peel in moderately coarse powder, Coriander in moderately coarse powder, each sixty grains; Alcohol two fluidounces; Water a sufficient quantity. Mix the alcohol with fourteen fluidounces of water, and, having moistened the mixed powders with three fluidrachms of the menstruum, pack them firmly in a conical percolator, and gradually pour upon them first the remainder of the menstruum, and then water, until the filtered liquid measures a pint. *U. S.*

Take of Gentian Root sliced one-quarter ounce; Bitter Orange Peel cut small, Coriander Fruit bruised, each thirty grains; Proof Spirit two fluidounces; Distilled Water eight fluidounces. Macerate the gentian, orange peel, and coriander in the proof spirit for two hours, then add the water, macerate again for two hours, and strain through calico. *Br.*

The alcohol is present in sufficient quantity to preserve the infusion unaltered for some days. As it is an elegant preparation, frequently prescribed in small quantities, J. T. Shinn (1862) proposed to exhaust four times the weight of material directed, by percolation with diluted alcohol sufficient for obtaining one pint of tincture, four fluidounces of which, diluted with twelve fluidounces of water, will exactly represent one pint of the officinal infusion of the United States Pharmacopœia.

Infusum gentianæ compositum, of the British Pharmacopœia, is made as follows:—

Take of Gentian Root sliced, Bitter Orange Peel cut small, each sixty grains; Fresh Lemon Peel cut small one-quarter ounce; Boiling Distilled Water ten fluidounces. Infuse in a covered vessel for one hour, and strain. *Br.*

Medical Uses.—This is an agreeable and efficient stimulant stomachic tonic, and may be used in *doses* of a fluidounce two or three times a day.

INFUSUM HUMULI, *U. S.*—INFUSION OF HOPS.

Infusum lupuli, Br.—*Tisane de houblon*, Fr.; *Hopfenaufguss*, G.

Preparation.—Take of Hops half a troyounce; Boiling Water a pint. Macerate for two hours in a covered vessel, and strain. *U. S.*

Take of Hop one-half ounce; Boiling Distilled Water ten fluidounces. Infuse in a covered vessel for two hours, and strain. *Br.*

Medical Uses.—It is the most eligible form for the administration of hop when alcohol is contraindicated. *Dose*, from two to four fluidounces every two or three hours.

INFUSUM JUNIPERI, *U. S.*—INFUSION OF JUNIPER.

Tisane de genièvre, Fr.; *Wachholderbeeren-Aufguss*, G.

Preparation.—Take of Juniper bruised a troyounce; Boiling Water a pint. Macerate for an hour in a covered vessel, and strain. *U. S.*

Medical Uses.—This preparation has the stimulant and diuretic virtues of juniper in a high degree, and is much used in *dropsies* and in chronic affections of the urinary passages. Most frequently its operation as a diuretic is increased by the addition of acetate of potassium, or the association with it of parsley, horseradish, etc. *Dose*, a wineglassful or two every three or four hours.

INFUSUM KRAMERIÆ, *U. S.*, *Br.*—INFUSION OF RHATANY.

Tisane de ratanhia, Fr.; *Ratanha-Aufguss*, G.

Preparation.—Take of Rhatany in moderately coarse powder a troyounce; Water a sufficient quantity. Moisten the powder with half a fluidounce of water, and, having packed it firmly in a conical glass percolator, gradually pour water upon it until the filtered liquid measures a pint. *U. S.*

Take of Rhatany Root bruised one-half ounce; Boiling Distilled Water ten fluidounces. Infuse in a covered vessel for one hour, and strain. *Br.*

Medical Uses.—In all cases of internal *hemorrhage* to which astringents are applicable, this infusion may be advantageously used, the more so the more passive the bleeding. It is also useful in *mucous profluvia* of the bronchia and the gastro-intestinal tube. A watery solution of the extract of rhatany is, however, generally preferable. *Dose*, two fluidounces.

INFUSUM LINI COMPOSITUM, *U. S.*—COMPOUND INFUSION OF FLAXSEED.

Infusum lini, Br.—*Infusion of linseed*, E.; *Tisane de lin*, Fr.; *Leinsamenaufguss*, G.

Preparation.—Take of Flaxseed half a troyounce; Liquorice Root bruised one hundred and twenty grains; Boiling Water a pint. Macerate for two hours, in a covered vessel, and strain. *U. S.*

Take of Linseed one hundred and sixty grains; Fresh Liquorice Root sliced sixty grains; Boiling Distilled Water ten fluidounces. Infuse in a covered vessel, for four hours, and strain. *Br.*

Liquorice root is added in this infusion with the view of improving its flavor. As the mucilage is contained in the covering of the seed, it should not be bruised, otherwise the oil will be emulsionized, and the swelling of the entire tissue will prevent the straining of the liquid.

Medical Uses.—The apparent intention of this preparation is to provide an appropriate remedy for acute mucous inflammations of the respiratory tract, an object which scarcely required a special formula, since in domestic practice it is customary to add liquorice, or sugar, or lemon juice to flaxseed tea, for these affections. The liquorice, also, renders this infusion less appropriate for bowel and urinary disorders, to which the simple infusion is generally well adapted. It may be drunk freely.

INFUSUM LUPULI, *Br.* See INFUSUM HUMULI.

INFUSUM MATICÆ, *Br.*—INFUSION OF MATICO.

Tisane de matico, Fr.; *Matico-Aufguss*, G.

Preparation.—Take of Matico Leaves cut small half an ounce; Boiling Distilled Water ten fluidounces. Infuse in a covered vessel for two hours, and strain. *U. S.*

Medical Uses.—This astringent but not very efficient preparation may be prescribed in *doses* of a fluidounce or more.

INFUSUM PAREIRÆ, *U. S.*—INFUSION OF PAREIRA BRAVA.

Tisane de pareira, Fr.; *Pareira-Infusion*, G.

Preparation.—Take of Pareira Brava bruised a troyounce; Boiling Water a pint. Macerate for two hours, in a covered vessel, and strain. *U. S.*

Medical Uses.—The infusion of pareira is the most suitable form for administering this drug in cases to which it is appropriate, such as chronic inflammations of the *urinary organs*, especially those which are attended with calculous deposits. In this country it is seldom used. *Dose*, one or two fluidounces.

INFUSUM PICIS LIQUIDÆ, *U. S.*—INFUSION OF TAR.

Aqua picis, P. G.; *Aqua picea.*—*Tar water*, E.; *Eau de goudron*, Fr.; *Theerwasser*, G.

Preparation.—Take of Tar a pint; Water four pints. Mix them, and shake the mixture frequently during twenty-four hours. Then pour off the infusion, and filter through paper. *U. S.*

The large quantity of resinous and oily principles present in tar interferes with the solvent action of cold water; hence the Pharmacopœia directs a large quantity of the former the more easily to saturate the latter, which during the brief contact will mainly extract acetic and other acids. The use of magnesia for dividing the tar is inadmissible on account of the formation of soluble salts. The German Pharmacopœia directs one part of tar to ten parts of boiling distilled water, and maceration for two days, with frequent stirring. The French Codex leaves the tar for a day in contact with thirty parts of water, and rejects this strongly acid infusion, the remaining tar being again macerated with thirty parts of water for eight or ten days. Magnes-Lahens (1876) observed that if tar be pulverized by the admixture of twice its weight of inert sawdust, 27 grams of this mixture will yield to 1 liter of water 6 grams of extract, which is a saturated solution. Lefort (1868) determined the amount taken up by hot water to be 2 grams to the liter.

Medical Uses.—Tar water is useful in chronic disorders of the mucous membranes of the pulmonary and urinary tracts, but in the former especially. It was once famous as a remedy for "consumption" and numerous other diseases, but its utility it now found to be limited to *chronic bronchitis*, in which it lessens the discharge, and gradually, and like other terebinthinates, restores the affected membrane more or less perfectly to its original integrity; and to mucous disorders of the *urinary organs*, in which it acts by impregnating the urine, as well as through the blood. In the last-named diseases tar and its preparations are less eligible than balsamic medicines, owing, probably, to the acid that it contains. *Dose*, one or two ounces three or four times a day, and increased without definite limitation.

INFUSUM PRUNI VIRGINIANÆ, *U. S.*—INFUSION OF WILD CHERRY.

Tisane d'écorce de cerisier sauvage, Fr.; *Wildkirschen-Thee*, G.

Preparation.—Take of Wild Cherry in fine powder half a troyounce; Water a sufficient quantity. Moisten the powder with six fluidrachms of water, and let it stand for an hour; pack it firmly in a conical glass percolator, and gradually pour water upon it until the filtered liquid measures a pint. *U. S.*

Made with cold water as directed by the Pharmacopœia, this infusion contains volatile oil and hydrocyanic acid, which are not generated by the use of hot water.

Medical Uses.—This is the best form in which wild cherry bark can be used, as a mild tonic and cardiac sedative. It is especially applicable to the treatment of irritative *dyspepsia*, *nervous cough*, the cough of early pulmonary *phthisis*, and the hectic irritation of the decline of that disease. *Dose*, two or three fluidounces several times a day.

INFUSUM QUASSIÆ, *U. S.*, *Br.*—INFUSION OF QUASSIA.

Tisane de quassie, F.; *Quassia-Aufguss*, G.

Preparation.—Take of Quassia rasped one hundred and twenty grains; Water a pint. Macerate for twelve hours in a covered vessel, and strain. *U. S.*

Take of Quassia Wood in chips sixty grains; Cold Distilled Water ten fluidounces. Macerate in a covered vessel for half an hour, and strain. *Br.*

We can perceive no objection to the use of warm water in making this infusion, whereby time might be materially economized, without interfering with the appearance or efficiency of the preparation.

Medical Uses.—Infusion of quassia is the purest of bitter infusions, and is the best form for administering this useful stomachic tonic. The *dose* is two fluidounces three times a day.

INFUSUM RHEI, *U. S.*, *Br.*—INFUSION OF RHUBARB.

Tisane de rhubarbe, Fr.; *Rhabarber-Aufguss*, G.

Preparation.—Take of Rhubarb bruised one hundred and twenty grains; Boiling Water half a pint. Digest for an hour in a covered vessel, and strain. *U. S.*

Take of Rhubarb Root in thin slices one-quarter ounce; Boiling Distilled Water ten fluidounces. Infuse in a covered vessel for one hour, and strain. *Br.*

Rhubarb being easily permeated by water, it is preferable to employ it for this purpose cut into thin slices, instead of bruising it; in the latter case the finer powder should be sifted off. But in either case the preparation is unsightly, and becomes still more so by the long-continued digestion directed in the first formula. A handsomer though weaker infusion is obtained with the French Codex by maceration for four hours with cold water. In Germany a preparation has long been in use under the name of *Infusum rhei kalinum* or *Tinctura rhei aquosa*, which is now prepared as follows: Take of Rhubarb sliced one hundred parts; Borax and Potassium Carbonate, each ten parts; Boiling Distilled Water eight hundred and fifty parts. Infuse for fifteen minutes, add Alcohol one hundred parts, and macerate for one and a quarter hour; then express lightly, and to the filtrate add Cinnamon Water one hundred and fifty parts. The finished preparation will weigh 1000 parts, represents nearly 10 per cent. of rhubarb, and mixes clear with aqueous liquids, but is incompatible with all preparations which are decomposed by alkalies. It may be preserved for several months, if kept in small vials and in a cool place.

Medical Uses.—This infusion is seldom prescribed, either alone or as a vehicle for other purgatives. In the latter case it has been associated with salines, such as the tartrate of sodium or the bitartrate of potassium. The diluted form of this preparation is probably not without its advantages in maintaining a moderate and sustained operation on the bowels. *Dose*, one or two fluidounces, repeated, if necessary, in three or four hours.

INFUSUM ROSÆ COMPOSITUM, *U. S.*—COMPOUND INFUSION OF ROSE.

Infusum rosæ acidum, Br.—*Acid infusion of rose*, E.; *Tisane de rose composée*, Fr.; *Saurer Rosenaufguss*, G.

Preparation.—Take of Red Rose half a troyounce; Diluted Sulphuric Acid three fluidrachms; Sugar in coarse powder a troyounce and a half; Boiling Water two pints and a half. Pour the water upon the rose in a covered glass or porcelain vessel, add the acid, and macerate for half an hour; then dissolve the sugar in the liquid, and strain. *U. S.*

Take of Dried Red-Rose Petals broken up a quarter of an ounce; Diluted Sulphuric Acid one fluidrachm; Boiling Distilled Water ten fluidounces. Infuse in a covered vessel for one hour, and strain. *Br.*

This infusion should not be made in a metallic vessel; it has a fine red color and agreeable flavor.

Medical Uses.—The compound infusion of rose is employed as a coloring and flavoring ingredient of mixtures, and as an excipient and solvent for sulphate of magnesia and for sulphate of quinia, whose taste it partially covers. It forms an agreeable gargle for inflamed and ulcerated states of the *mouth* and *fauces*, and may be used to moderate profuse *sweats*. Its virtues are mainly due to the sulphuric acid it contains. *Dose*, from two to four fluidounces.

INFUSUM SALVIÆ, *U. S.*—INFUSION OF SAGE.

Tisane de sauge, Fr.; *Salbeiaufguss*, G.

Preparation.—Take of Sage half a troyounce; Boiling Water a pint. Macerate for half an hour in a covered vessel, and strain. *U. S.*

Medical Uses.—As sage is almost always administered in infusion, the reader is referred to the article Sage for an account of the virtues of sage tea. Suffice it in this place to say that the infusion is especially valuable internally for controlling profuse *sweats* and an excessive secretion of *milk*, and locally for healing aphthous *ulcers* of the mouth, and giving tone to relaxed mucous membranes generally. *Dose*, two or more fluidounces. As a gargle, it may contain in solution alum, or chlorate of potassium, with the addition of honey, vinegar, muriatic acid, etc.

INFUSUM SENEGÆ, *Br.*—INFUSION OF SENEGA.

Tisane de polygale de Virginie, Fr.; *Senega-Aufguss*, G.

Preparation.—Take of Senega Root bruised half an ounce; Boiling Distilled Water ten fluidounces. Infuse in a covered vessel, and strain. *Br.*

The U. S. Pharmacopœia directs a decoction of senega. (See page 497.)

Medical Uses.—This preparation is supposed to possess certain advantages over the decoction of seneka (*U. S. P.*) which was originally prescribed, and continues to be preferred in this country, but as the senegin is not altered by the heat of boiling water, it is probable that decoction extracts a larger proportion of it than infusion does. *Dose*, one to two fluidounces.

INFUSUM SENNÆ, *U. S.*, *Br.*—INFUSION OF SENNA.

Tisane de séné composée, Fr.; *Senna-Aufguss*, G.

Preparation.—Take of Senna a troyounce; Coriander bruised sixty grains; Boiling Water a pint. Macerate for an hour in a covered vessel, and strain. *U. S.*

Take of Senna one ounce; Ginger sliced thirty grains; Boiling Distilled Water ten fluidounces. Infuse in a covered vessel for one hour, and strain. *Br.*

We believe that the long-continued infusion increases the tendency of the senna to produce griping, particularly if digestion be resorted to. If the leaves have been cut or bruised, digestion for not over ten minutes will yield an active infusion. The flavor being a matter of taste, the selection of aromatics had probably best be left to the physician. A *compound infusion or mixture of senna*, used in Great Britain under the name of *black draught*, is made by dissolving four ounces of magnesium sulphate and half an ounce of liquorice, together with two and a half fluidounces of tincture of senna, and ten fluidrachms of compound tincture of cardamom, in sufficient infusion of senna to obtain one imperial pint. The German Pharmacopœia directs an *infusum sennæ compositum*, which is also known as *Aqua* (*s. Potio*) *laxativa Viennensis* or *Vienna draught;* it is made by macerating two parts of cut senna with twelve parts of boiling water, exposing it to the heat of a steam-bath for five minutes, and stirring frequently; the liquid is then expressed, and two parts of sodium and potassium tartrate, and three parts of manna dissolved in it; when finished it should weigh fifteen parts.

Medical Uses.—The coriander seed in this preparation lessens the tendency of the senna to gripe. If the infusion is allowed to macerate too long, the tendency is increased. This preparation is much less frequently used than a non-officinal infusion which contains also manna and sulphate of magnesia, with fennel seed, and is known as *black draught*. The *dose* of the officinal infusion is about four fluidounces. Of the other preparation the dose should vary with the proportions of the several ingredients, and these with the nature of the case. The most usual formula, however, is the following: ℞. Sennæ, ℥ss; Magnesiæ sulph., mannæ, āā ℥j; Sem. fœniculi, ʒj; Aquæ bull., Oss. Macerate in a covered vessel until the liquid cools. *Dose*, two to four ounces every three or four hours until it operates.

INFUSUM SERPENTARIÆ, *U. S.*, *Br.*—INFUSION OF SERPENTARIA.

Infusion of serpentary, E.; *Tisane de serpentaire*, Fr.; *Schlangenwurzel-Aufguss*, G.

Preparation.—Take of Serpentaria in moderately coarse powder half a troyounce; Water a sufficient quantity. Moisten the powder with two fluidrachms of water, pack it firmly in a conical percolator, and gradually pour water upon it until the filtered liquid measures a pint.

Or, macerate the serpentaria in a pint of boiling water for two hours in a covered vessel, and strain. *U. S.*

Take of Serpentary Root bruised one-quarter ounce; Boiling Distilled Water ten fluidounces. Infuse in a covered vessel for two hours, and strain. *Br.*

Medical Uses.—This preparation is preferable to the fluid extract and to the tincture of serpentaria. Its uses are fully detailed under Serpentaria, and it was, indeed, until recently the only preparation of the medicine in use. *Dose*, one or two fluidounces every two or three hours in typhoid conditions.

INFUSUM SPIGELIÆ, *U. S.*—INFUSION OF SPIGELIA.

Tisane de spigélie du Maryland, Fr.; *Spigelien-Aufguss*, G.

Preparation.—Take of Spigelia half a troyounce; Boiling Water a pint. Macerate for two hours in a covered vessel, and strain. *U. S.*

Medical Uses.—The anthelmintic and alterative operations of this medicine will be found treated of under Spigelia. The infusion is rendered more efficient as an anthelmintic for lumbricoid worms by the association of other medicines, as in the medicine known as *worm tea:* ℞. Spigelia, ℥ss; Sennæ, Sem. fœniculi, āā ʒij; Mannæ, ℥j; Aquæ bullient. Oj.—Infuse. *Dose* for a child two years old, one fluidounce.

INFUSUM TABACI, *U. S.*—Infusion of Tobacco.

Infusion de tabac, Fr.; *Tabakaufguss*, G.

Preparation.—Take of Tobacco sixty grains; Boiling Water a pint. Macerate for an hour in a covered vessel, and strain. *U. S.*

A similar preparation is officinal in the British Pharmacopœia as *Enema tabaci.* (See page 529.)

Medical Uses.—Infusion of tobacco has been applied externally as a wash to destroy cutaneous parasites, and in the treatment of *scabies*, *prurigo*, *pityriasis*, etc.; but numerous instances of poisoning by this mode of its application suffice to condemn it. Internally, infusion of tobacco has been used to relax *muscular spasm* of the glottis, bronchia, intestine, bladder, uterus, etc., in tetanus also, and in poisoning by strychnia. It has also been prescribed in various forms of *dropsy.* For details, see Tobacco. The preparation is not used internally, except by enema, when half a pint may be given, and, if required, the same quantity may be repeated in half an hour, if no sign of poisoning appear.

INFUSUM TARAXACI, *U. S.*—Infusion of Dandelion.

Tisane de pissenlit, Fr.; *Löwenzahn-Aufguss*, G.

Preparation.—Take of Dandelion bruised two troyounces; Boiling Water a pint. Macerate for two hours in a covered vessel, and strain. *U. S.*

Medical Uses.—The medicinal virtues of this preparation will be found described under Taraxacum. It possibly exerts some depurative action upon the digestive glandular system. *Dose*, two fluidounces two or three times a day.

INFUSUM UVÆ URSI, *Br.*—Infusion of Bearberry.

Tisane d'uva ursi, Fr.; *Bärentraubenblätter-Aufguss*, G.

Preparation.—Take of Bearberry Leaves bruised half an ounce; Boiling Distilled Water ten fluidounes. Infuse in a covered vessel for two hours, and strain. *Br.*

The corresponding preparation of the U. S. Pharmacopœia is made by boiling for 15 minutes (see page 498.)

Medical Uses.—This is a more convenient form than the decoction for extemporaneous use, and is perhaps sufficiently active, since it is certain that the amount of tannic and gallic acids which can be profitably absorbed from the stomach is not unlimited. *Dose*, one or two fluidounces.

INFUSUM VALERIANÆ, *U. S.*, *Br.*—Infusion of Valerian.

Tisane de valériane, Fr.; *Baldrian-Aufguss*, G.

Preparation.—Take of Valerian in moderately coarse powder half a troyounce; Water a sufficient quantity. Moisten the powder with two fluidrachms of water, pack it firmly in a conical percolator, and gradually pour water upon it until the filtered liquid measures a pint. Or, macerate the valerian in a pint of boiling water for two hours in a covered vessel, and strain. *U. S.*

Take of Valerian Root bruised one hundred and twenty grains; Boiling Distilled Water ten fluidounces. Infuse in a covered vessel for one hour, and strain. *Br.*

Medical Uses.—Although partially superseded by the more convenient fluid extract and tinctures, the infusion of valerian is, nevertheless, a valuable preparation, particularly where the medicine must be continuously given. *Dose*, two fluidounces.

INFUSUM ZINGIBERIS, *U. S.*—INFUSION OF GINGER.

Tisane de gingembre, Fr.; *Ingwer-Aufguss*, G.

Preparation.—Take of Ginger bruised half a troyounce; Boiling Water a pint. Macerate for two hours in a covered vessel, and strain. *U. S.*

Medical Uses.—This infusion, when given hot, is an excellent remedy for flatulent *colic*, and is sometimes useful in promoting expectoration in *senile catarrh.* As a gargle it may be employed to correct relaxation of the *uvula*, and *aphonia* due to a similar condition of the vocal cords. *Dose*, one or two fluidounces.

INJECTIO MORPHIÆ HYPODERMICA.—*Br. Add.*

Hypodermic injection of morphia, E.; *Injection hypodermique au morphine*, Fr.; *Subcutane Morphineinspritzung*, G.

Preparation.—Take of Hydrochlorate of Morphia eighty-eight grains; Solution of Ammonia, Acetic Acid, Distilled Water, of each a sufficiency. Dissolve the hydrochlorate of morphia in two ounces of distilled water, aiding the solution by a gentle heat; then add solution of ammonia so as to precipitate the morphia, and render the liquid slightly alkaline; allow it to cool; collect the precipitate on a filter, wash it with distilled water, and allow it to drain; then transfer the morphia to a small porcelain dish with about an ounce of distilled water, apply a gentle heat, and carefully add acetic acid until the morphia is dissolved, and a very slightly acid solution is formed. Add now sufficient distilled water to make the solution measure exactly two fluidounces. Filter and preserve the product in a stoppered bottle excluded from the light. *Br.*

The object of the above process is the preparation of acetate of morphia in solution of definite strength so that each fluidrachm shall contain five grains of that salt. On keeping the solution decomposes, acquiring a brown color and slowly separating morphia, the crystals being very long if the solution remained undisturbed. To prevent this decomposition Prof. C. Johnston (1873) recommended sulphurous acid, five drops of which were found by Jennings sufficient to protect a fluidounce. Squibb (1873) observed that one-sixth per cent. of pure carbolic acid would preserve such solutions, and Limousin (1876) has obtained satisfactory results by using one-fifth per cent. of salicylic acid.

Medical Uses.—The average hypodermic *dose* of this preparation is from one to six minims, equal to from one-twelfth of a grain to half a grain of the salt.

INULA, *U. S.*—ELECAMPANE.

Radix Helenii, P. G.; *Radix inulæ, Radix enulæ.*—*Racine d'aunée, Aunée commune* (*officinale*), Fr.; *Alantwurzel, Helenenwurzel*, G.

The root of Inula helenium, *Lin.* (Corvisartia helenium, *Merat*). Woodville, Med. Bot., t. 26; Bentley and Trimen, Med. Plants, 150.

Nat. Ord.—Compositæ, Asteroideæ.

Origin.—Elecampane is a native of Central Asia and Southern Siberia, and is found westward to Southern and Central Europe. It is not unfrequently cultivated, and has in many places escaped from gardens and become naturalized. In the United States it grows spontaneously along roadsides and in pastures, from New England south to the mountains of North Carolina, and westward to Illinois. It has a thick solid stem 3 to 6 feet high, large radical leaves decurrent on the long petioles, and sessile clasping stem-leaves, all being acute, somewhat toothed, and grayish hairy on the lower surface. The large flower-heads are terminal, and have a loosely imbricated involucre with an outer series of foliaceous ovate bracts; the numerous yellow pistillate ray-florets are ligulate, linear, and three-toothed, and the yellow disk-florets tubular and 5-toothed. The akenes are smooth, pale brown, four-sided, and crowned with a hairy pappus. The root is collected in the fall of the second or the spring of the third year.

Description.—The root is about six inches long and 1 or 2 inches thick, divided below into branches 6 to 12 inches long and $\frac{1}{2}$ to 1 inch thick, very fleshy, in commerce always sliced either longitudinally or transversely. The longitudinal slices have the bark overlapping; the transverse slices are concave, somewhat radially striate; externally irregularly wrinkled and brownish, internally white when fresh, grayish after drying, of a peculiar aromatic odor, and an aromatic, bitterish, and pungent taste. The root is hygroscopic and flexible in damp weather, but when dry breaks with a short fracture. The bark is $\frac{1}{8}$ inch and more thick, the inner portion radiate near the cambium line; the meditullium is not very distinctly radiate with small fibro-vascular bundles; all parts of the root are dotted with shining yellowish-brown resin cells.

Constituents.—Elecampane contains a little *volatile oil*, some acrid *resin*, a *bitter principle* not known as yet in the isolated state, *waxy matter, inulin*, etc. Since 1873, Kallen has investigated the body formerly known as helenin and elecampane camphor, which crystallizes from the concentrated tincture mixed with water. He isolated from it *helenin*, C_6H_8O, which is insipid, crystallizes in needles, and fuses at 110° C. (230° F.); *inulol*, which is a camphor isomeric with laurel-camphor, and the anhydrid of a peculiar acid called *inulic acid.* The odor and camphoraceous taste are due to inulol. *Inulin*, $C_{12}H_{20}O_{10}$, is contained in the subterraneous parts of compositæ, and is obtained by forcibly expressing the grated juicy roots, when a portion will deposit on standing, and the remainder may be precipitated by alcohol; dry roots are first deprived of coloring matter, etc., by cold water, then slowly heated with water, expressed, and precipitated by cooling or by alcohol. The autumn roots contain the largest percentage (elecampane 44 per cent.) of inulin, which by the following spring is to a considerable extent changed into mucilage, sugar, and levulin, and in some cases to glucosides. Inulin is a fine white powder, tasteless and inodorous, slightly soluble in cold water, more so in hot water, and then partly decomposed but mostly reprecipitated on cooling. It differs from starch by the absence of concentric layers, does not yield a jelly with water, and it is colored yellow (not blue) by iodine. Two monographs on inulin were published in 1870, one by Prof. Dragendorff, the other by Dr. K. Prantl.

Medical Action and Uses.—Inula was one of the most famous of ancient medicines, and continued in vogue until very recent times. It owed this reputation to its stimulant qualities. Even in the Hippocratic writings it is stated to be a stimulant of the brain, the stomach, the kidneys, and the uterus, qualities which continued to be ascribed to it, as well as a rubefacient action upon the skin. It had a special reputation in all pulmonary affections, and as a topical application in sciatica, gout, gravel, facial neuralgia, etc. One of its chief constituents, inulin, is probably quite negative; and whatever virtues the plant possesses must be due to the elecampane camphor, which it contains in small proportion, to its very minute quantity of volatile oil, and to the bitter extractive which it holds in as large a proportion as of inulin. These elements are apparently too insignificant to justify the ancient repute of elecampane. It continues to be used as a domestic remedy, rather than by physicians, in the treatment of chronic *bronchitis*, *dyspepsia*, *amenorrhœa* and other menstrual disorders. It is also preserved as a candy, like calamus, and is used to flavor the alcoholic beverage *absinthe*. Its retention in the United States Pharmacopœia seems quite superfluous. Elecampane is generally administered in a decoction prepared by boiling half an ounce of the root in a pint of water, and which may be given in the *dose* of two or more fluidounces.

IODINIUM, *U. S.*—IODINE.

Iodum, Br., P. G.—*Iode*, Fr.; *Jod*, G.
Symbol I. Atomicity univalent. Atomic weight 127.

A non-metallic element, obtained principally from the ashes of sea-weeds.

Origin.—Iodine is found in some minerals combined with mercury, silver, lead, and other metals, in Chili saltpetre principally as sodium iodate, in many mineral-spring waters, in sea-water, and in many plants and animals living in sea-water or near the sea coast. It is often a constituent of the atmosphere in minute quantities, and occasionally of the ashes of some plants growing inland.

Preparation.—Large quantities are made from *kelp*, the ash left on the burning of sea-weeds. The weed is first dried, and then charred or burned at as low a temperature as possible to avoid loss of iodine. The ash is exhausted with hot water, and the solution concentrated and cooled to remove by crystallization potassium chloride and sodium carbonate and sulphate. More of the latter salt will crystallize after the addition of some sulphuric acid, whereby the sulphides and hyposulphites present are decomposed. The mother-liquor is then mixed with binoxide of manganese, and in lead retorts heated to a temperature a little over 60° C. (140° F.), when iodine will distil over and is collected in glass receivers, several of which are connected with each other. The liberation of iodine from the sodium iodide of the liquor is explained by the following equation: $2NaI+3H_2SO_4+MnO_2=I_2+2NaHSO_4+MnSO_4+2H_2O$, acid sodium sulphate and manganium sulphate being formed at the same time. The mother-liquor obtained on the purification of Chili saltpetre contains sodium iodate and iodide; from the latter the iodine is separated by chlorine gas, from the former by sulphurous acid, in which case sodium sulphate is produced.

Purification.—In the crude state iodine is chiefly contaminated with water, but it sometimes contains also cyanogen iodide, and occasionally iodine chloride, ICl. Purification is effected by drying the product as much as possible by mechanical means, and then subliming it carefully, so that the more volatile compounds named may first sublime; afterwards the heat is raised, and the receiver changed. The product is the *resublimed iodine* of commerce.

Properties.—Iodine is in flat scale-like rhombic crystals of a grayish-black color and a bright metallic lustre, in thin splinters transparent with a red color. It is soft and friable, and has an odor suggestive of chlorine, and a very caustic and acrid taste. The skin or paper is transiently colored brown, and vegetable colors are slowly destroyed by it. It has the specific gravity 4.95, fuses near 115° C. (239° F.), congeals at 113.6° C. (236.5° F.), and boils above 175° C. (347° F.); its vapor has the density 8.7, and a reddish or purple, or, above the boiling point, a deep-blue color. Iodine dissolves in about 60 parts of glycerin, and in 7000 parts (Gay-Lussac) (65,000 parts according to Dossios and Weith) of water, and forms with it gradually hydriodic acid, which dissolves more iodine; its solubility in water is also increased by many salts, and particularly by iodides. It is freely soluble in alcohol and ether with a brown color, and in chloroform, carbon bisulphide, and hydrocarbons with a purplish or violet color. It combines in several proportions with oxygen, the most important compound being *iodic acid;* it unites with hydrogen to hydriodic acid, and combines with most of the other elements.

Tests.—Iodine is readily recognized by the blue color which it imparts to starch paste, and by which $\frac{1}{400,000}$ part of free iodine is still recognized. Water containing traces of free iodine will yield it to carbon bisulphide, etc., in which solution it is recognized by the purplish color and by the blue color produced with starch paste. Iodine in combination must previously be liberated by chlorine gas, avoiding an excess of the latter; or, if present as iodate, sulphurous acid or other deoxidizing agent will set it free.

Impurities and Adulterations.—At present, iodine is usually met with in commerce in a very pure condition, containing but minute quantities of impurities. An excessive proportion of water is indicated by the iodine adhering to the bottle, and may be removed by placing it under a bell-glass over oil of vitriol at a low temperature. The presence of cyanogen iodide and iodine chloride is detected by heating the iodine in a suitable apparatus for about 15 minutes to 100° C. (212° F.), and cooling the vapors well; the former impurity will sublime as white or yellowish needles, the latter as hyacinthine-red prisms or red-brown oil; both have a pungent odor. Fixed impurities, such as graphite, charcoal, sawdust, metallic compounds, etc., are left behind on volatilizing a little from a porcelain capsule. The British Pharmacopœia directs 12.7 grains of iodine to be dissolved in an ounce of water containing 15 grains of potassium iodide; if no impurities whatever are present, the solution requires for complete discoloration 1000 grain measures of the volumetric solution of hyposulphite of sodium.

Pharmaceutical Uses.—Iodine is used in the following preparations:—

AMYLI IODIDUM, Iodide of starch, *E.;* Iodure d'amidon, *Fr.;* Jodstärke, *G.* According to Quesneville (1868), it may be obtained both in a soluble and an insoluble state as follows: 1050 parts of starch and 100 parts of iodine, both in fine powder, are well mixed and then triturated with a mixture of 400 parts of water and 100 of alcohol, the liquid to be added gradually; the whole is left in contact for 15 or 20 days, and afterwards carefully dried. Thus prepared, it is a dark blackish-blue powder, has no odor of iodine, and contains 10 per cent. of this element. To obtain it soluble, it is heated in a porcelain or enamelled dish over a slow fire, and with continued agitation, until a pungent odor commences to be given off. This may be still further purified by making a concentrated solution in warm water, precipitating the clear liquid by alcohol, drying, and powdering the precipitate.

Fritzsche obtained it by adding tincture of iodine to a filtered solution of starch in concentrated hydrochloric acid. Bondonneau (1878) dissolves the starch first in caustic soda and precipitates the slightly acidulated solution with tincture of iodine. Liebig regarded iodide of starch as a mere mixture of starch with finely divided iodine; Payen and Fritzsche as a definite compound, $(C_6H_{10}O_5)_{10}I$, and Bondonneau gives it the formula $(C_6H_{10}O_5)_5I$, equal to 13 per cent. of iodine, the latter being dissolved by alcohol, but not by potassium iodide, benzin, sulphide of carbon, or other solvents. According to the process adopted, the amount of iodine varies, and though generally about 7.5 per cent., may be as low as 3.2 per cent., or, as obtained by Lassaigne, as high as 41.75 per cent.

Exposed to the sunlight, iodide of starch is decolorized; when heated with water to 65° C. (149° F.) it becomes colorless, and blue again on cooling; but when heated to boiling, iodine is given off, and may be completely expelled by continuing the heat for a sufficient length of time.

Syrup of Iodotannin.—Debauque observed that a solution of tannin will dissolve a considerable amount of iodine without reacting with starch. Demolon has suggested a syrup containing this compound, which is made by dissolving 3 grams of iodine and 18 grams of tannin in 300 grams of water, evaporating the solution until 60 grams are left, which are mixed with 960 grams of simple syrup.

Iodine is contained in the following officinal chemical compounds: Arsenici iodidum, *U. S.;* Cadmii iodidum, Ferri iodidum, *Br.;* Hydrargyri iodidum rubrum, Hydrarg. iodid. viride, *U. S.*, *Br.;* Iodoformum, *U. S.;* Plumbi iodid., Sulphuris iodidum, *U. S.*, *Br.*

The following pharmaceutical preparations likewise contain combined iodine: Linim. potass. iodidi cum sapone, *Br.;* Liquor arsen. et hydrarg. iodidi, *U. S.;* Pilula ferri iodidi, Syrup. ferri iodidi, *U. S.*, *Br.;* Unguent. cadmii iodidi, *Br.;* Ung. hydrarg. iodidi rubri, Ung. plumbi iodidi, Ung. potass. iodidi, Ung. sulphur. iodidi, *U. S.*, *Br.*

The following preparations contain free iodine: Linim. iodi, *Br.;* Liquor iodinii comp. (iodi), *U. S.*, *Br.;* Tinct. iodinii, *U. S.;* Tinct. iodinii comp. (iodi), *U. S.*, *Br.;* Ung. iodinii, *U. S.;* Ung. iodinii comp. (iodi), *U. S.*, *Br.;* Vapor iodi, *Br.*

Medical Action. *On Plants and Animals.*—Iodine, being one of the most widely diffused of elementary bodies, may be presumed to be in harmony with life, and, in fact, it does promote the growth of vegetable organisms, when its proportion is minute, while it hinders it and destroys their vitality when in excess. The proportion which may become hostile to animal life is exceedingly small, and it operates slowly and gradually by impairing nutrition, especially of glandular organs, while it occasions more or less irritation of the gastro-intestinal mucous membrane. The latter effect reaches ulceration when the dose is increased; and if a very large dose be at once given, the effects are those of a corrosive poison.

On Man.—Applied to the skin in ointment or in solution, iodine occasions a sense of warmth in the part, which, if the preparation be very strong, may amount to painful burning, and cause redness and swelling of the surrounding integument. The tincture stains the skin yellow; the color is more or less permanent, and may only disappear with the exfoliation of the cuticle. It may be removed by solution of ammonia. It has generally been believed that iodine is absorbed by the skin; but carefully conducted experiments appear to show that, at least in adults, when efficient means are taken to prevent the iodine vapors from reaching the mouth and nostrils, no trace of the substance can be found in the secretions. The rare cases of alleged poisoning by the application of iodine to the unbroken skin, are contradicted by the experiments referred to. In children, however, the tincture of iodine applied to the unbroken scalp is said to have been absorbed, since its presence was detected in the urine, which, at the same time, becomes slightly albuminous.

The raw cutis, the mucous and the serous membranes, and the connective tissue, present an easy access for this substance to the bloodvessels. It does not usually occasion severe inflammation when so applied, probably from the rapidity of its absorption. When the vapors of iodine are inhaled, they irritate the mucous membranes and occasion headache, coryza, lachrymation, and cough. Their prolonged operation, as in certain manufactures, gives rise to dryness of the respiratory tract, dizziness, nervous disorder, etc. Absorbed iodine is readily detected, combined with sodium or potassium, in the blood, milk, tears, saliva, urine, serous effusions in closed cavities, etc. It is excreted chiefly by the kidneys, as an alkaline iodide, even when it is taken into the stomach, and sometimes it occasions a temporary albuminuria.

The direct effects of large doses of iodine (5–6 grains), taken internally, are those of an irritant poison, such as heat and constriction of the throat, nausea, eructation, salivation, epigastric pain, vomiting, diarrhœa, and collapse. If reaction takes place, the skin is apt to become intensely red. Notwithstanding the great severity of the symptoms, the death of a previously healthy person by the internal use of iodine is extremely rare, a circumstance due, doubtless, to its rapid absorption and elimination. On the other hand, medicinal doses have been known to occasion spasm of the larynx and severe gastric irritation, while very large doses have been taken at once, or excessive amounts in the course of a few weeks, without serious consequences. As an example of the former sort, may be mentioned the case of a young man who swallowed a solution containing more than two and a half drachms of iodine, without experiencing any remarkable effects; and, as an instance of the latter, the case of a woman who, in the course of eighty days, took nine hundred and fifty-three grains of iodine, in the form of tincture, without injury.

The chronic effects of iodine are manifested by all the organs. In the nasal passages, throat, and alimentary canal, there are signs of irritation, with coryza, dryness, burning pain, dyspepsia, and diarrhœa; there is a tendency to loss of flesh, and to wasting of certain glandular organs, especially the mammæ and the testicles; the nervous system suffers from mental and sensory debility, impaired muscular power, and even general paralysis; the hair and the skin are apt to grow darker; and the latter is the seat of various eruptions. Usually on ceasing the use of the medicine recovery from these effects gradually takes place. In medicinal doses iodine appears to promote nutrition, and to stimulate glandular secretion. It is thought to excite the genital organs and increase the menstrual flow. Finally, it tends to prevent or to limit putrefaction, and thereby to correct the fetor arising from this process.

Medical Uses.—In the following description of the internal uses of iodine, its tinctures are intended, unless it is otherwise stated. In *intermittent fever* iodine displays decidedly curative virtues both in tropical malarial regions and in those of the temperate zones. The tincture has been given in doses of from five to fifteen minims three times a day largely diluted. *Typhoid fever* and other febrile affections have been treated by iodine, but without evident advantage. *Mercurial salivation* may be diminished by its internal use. The iodide of potassium is less certain in its effects; indeed, if we might reason from its evident power of reviving mercury long quiescent in the system, its action should be mischievous when salivation already exists. *Constitutional syphilis* has sometimes been treated with iodine, but the potassic iodide has supplanted it in this respect. *Hypertrophy* of glandular organs is often reduced by iodine, especially of the mammæ, testes, liver, and spleen, and of the thyroid gland in goitre. Indeed, it is probable that all cases of true goitre in persons under middle age are curable by iodine. For this purpose the compound solution should be administered in doses of from five to ten drops three times a day. Its action upon the other organs mentioned, unless, perhaps, the mammæ, is more equivocal. It has been used to reduce *polysarcia.* In all cases care should be taken to prevent the medicine from injuring the stomach, by giving it largely diluted, while the internal is supplemented by the external use of the medicine. In *scrofula* iodine is most efficient in the glandular forms unconnected with a characteristic deposit; over the latter it has no direct influence. On the other hand, it is of great service in promoting the healing of scrofulous ulcers, and caries of the same nature, especially in the chronic stages of that process. There is reason to believe that even *tabes mesenterica*, or scrofula of the mesenteric glands, may sometimes be cured, and often palliated, by this medicine, especially if it is given, as in other scrofulous affections, with cod-liver oil. In some cases of *ascites* dependent upon obstruction of the spleen, liver, or mesenteric glands, iodine has proved curative; but in such cases the iodide of potassium is preferable. *Chronic articular rheumatism*, and that peculiar disease known as *nodosity of the joints*, have been treated with iodine internally, the former more successfully than the latter. *Excessive lactation* has been controlled by this agent in small and repeated doses, which are also sometimes successful in arresting the *vomiting* of pregnancy. The dose in the latter case should not exceed two or three dops of the tincture, and should be largely diluted. Uterine disorders, indicating impaired activity of function, sometimes appear to be benefited by this medicine.

As a *topical* application iodine is used for its counter-irritant and its absorbent effects. *Erysipelas*, when superficial, has often been arrested by the use of the tinctures of iodine, and, as far as any local treatment can go, they would seem preferable to solutions of nitrate of silver, and other more or less caustic lotions. In *smallpox* it seems to retard the maturation of the vesicles, or even to prevent it altogether, and with this effect to avert pitting. But its operation is not too confidently to be relied on. Lieutenant Payer states that a mixture of iodine and collodion proved most efficacious against *frost-bite* during the Arctic voyage of the "Tegethoff" in 1872. In *burns* and *scalds* its stimulant, substitutive, and protective operations are often useful; and the same may be said of certain cutaneous diseases, as *psoriasis*, *herpes*, *acne*, *favus*, and *lupus*. In the two last-named affections a saturated solution of iodine in alcohol must be employed. The stimulant operation of iodine, as well as its deodorizing influence, are useful in *ozæna;* it is a valuable agent for inhalation in chronic affections of the air-passages, especially in *laryngitis* and *bronchitis*, both in their original form and in that which accompanies *phthisis*. Like other local irritants, it may cure *aphonia* depending upon relaxation or upon nervous debility. Iodine has been used topically in *diphtheria*, and probably with more advantage in this way than nitrate of silver. It is a most valuable topical agent in *leucorrhœa*, vaginal or uterine, and in chronic engorgements of the uterus. The same may be said of its utility in *gleet*, chronic *vesical catarrh*, and chronic *dysentery*. A gargle made with half an ounce of compound tincture of iodine in half a pint of water is efficient in mercurial *ptyalism;* and a weak solution, as of one grain of iodine in an ounce of water, is one of the best means of retarding or curing *retraction of the gums*. A strong solution of iodine forms one of the best applications to chronic *ulcers of the tonsils*, *fauces*, and *uterus*, and in *granular pharyngitis* and *conjunctivitis*, and in *blepharitis*.

In various chronic enlargements, especially of the superficial *glands*, iodine locally employed hastens the cure; and the same may be said of *mammary abscess*, and of more chronic forms of inflammation, such as affect the *joints*. It sometimes promotes the removal of *pleural* effusions, and is adapted to relieve *muscular rheumatism* of the chest and *pleurodynia*, and probably to mitigate *chronic peritonitis*. Injected into the tunica vaginalis testis, the tincture of iodine has long been used for the cure of *hydrocele*, after being diluted with two parts of water. In like manner it has been employed to produce adhesion of the opposite sides of other serous cavities, such as *hernial sacs*, *synovial bursæ*, and even *large joints*, as in the case of white swelling or *hydrarthrosis; ascites* independent of organic mechanical causes has been cured in this manner; but, as such cases are extremely rare, the evidence in regard to the value of the operation is scanty. When paracentesis is practised in *chronic pleurisy*, tincture of iodine is often injected, either to hasten the adhesion of the opposite pleural surfaces, or to correct the fetor of the pleural secretion, or both at once. In recent cases the injection may consist of a watery solution of iodine in the proportion of from two to five grains in a pint of water; in more chronic ones, a solution of one part of the compound tincture of iodine to four or five of water has sometimes been used. A similar method has been successfully employed in *hydrorachis*, and unsuccessfully in *hydrocephalus*. Injection of the tinctures of iodine has been extensively used in the case of *cysts* containing either serum, pus, blood, hydatids, or melicerous or atheromatous matter. In the case of ovarian serous cysts the operation has been remarkably successful when the tumor was unilocular. The puncture for evacuating the cyst and injecting the iodic liquid should be made above Poupart's ligament. Indolent *abscesses* and *fistulæ* of all kinds are curable by injections of a solution of iodine, which appears to act by covering the diseased surface with a protecting film, by stimulating its curative processes, and by correcting the fetor of its secretions. In the first and last respects iodine is superior to nitrate of silver. The tincture of iodine has also been injected into *pulmonary cavities* by means of the needles usually attached to aspirators, and the result appears to be that the operation is less mischievous than might have been expected. Indeed, in some cases where a single superficial cavity existed, the expectoration and general symptoms have for a time abated.

The best antidotes for a poisonous dose of an iodic preparation is starch or wheaten flour mixed with tepid water. White of egg and also milk are efficient. A solution of carbonate or bicarbonate of sodium may also be given as a chemical antidote. Free vomiting should be encouraged as long as the liquid rejected tinges blue a solution of starch. Opiates, counter-irritants, and rest of the stomach, are indicated to allay gastric irritation.

Administration.—Its dose in other forms represents about one-fourth of a grain of iodine. Iodine is seldom given, in substance, by the stomach. Its vapors are sometimes inhaled in laryngeal and pulmonary affections, and externally it is applied to the skin as iodized cotton, or in bags or pads containing it in powder. These latter methods are more efficient than painting the skin with solutions of iodine. The discoloration of the skin produced by it may be removed by ammonia, carbolic acid, soap liniment, or sulphite of soda. For internal administration the simple or the compound tincture is to be preferred.

IODINII BROMIDUM.—BROMIDE OF IODINE.

Bromure d'iode, Fr.; *Jodbromid*, G.
Formula IBr_5. Molecular weight 527.

Preparation.—Twenty parts of iodine are dissolved in sixty-three parts of bromine, and the solution heated for some time in a large flask to about 60° C. (140° F.) until it yields a clear solution with six or eight parts of water.

Properties.—Pentabromide of iodine is a dark reddish-brown liquid, resembling bromine in appearance and sensible properties, but yielding a perfectly transparent brown-red solution with less than six parts of water. Such a solution, containing 15 per cent. of the bromide, is found in commerce. When the compound is kept for some time at or above 63° C. (145.4° F.), the boiling point of bromine, a portion of the latter distils off, and monobromide of iodine, IBr, is left as a dark-brown sublimable crystalline mass.

Medical Uses.—A solution of two drops in a fluidounce of mucilage has been applied in *diphtheria*.

IODOFORMUM, *U. S.*—IODOFORM.

Iodoformium, P. G.—*Iodoforme*, Fr.; *Jodoform*, G.
Formula CHI_3. Molecular weight 394.

Preparation.—Iodoform is produced by the action of iodine in the presence of alkalies upon alcohol, aldehyd, ether, acetic ether, methylic alcohol, and in minute quantities when acting upon carbohydrates or protein compounds. Wilder (1875) recommends Bouchardat's process as an easy one, and Filhol's as one giving a large yield. By following the former, 100 parts iodine, 100 potassium bicarbonate, 1200 water, and 250 alcohol are mixed in a flask with a long neck and slowly heated to between 60° and 80° C. (140° and 176° F.), until the color has disappeared, when 25, 20, and 10 parts of iodine are to be added, waiting after each addition, until the iodine color has disappeared, and adding, at the close, if necessary, a little potassa; after setting aside for 24 hours the crystals are collected upon a filter. About one-third of the iodine is recovered as iodoform, the remainder appearing in the mother-liquor chiefly as iodide of potassium, and may be obtained by supersaturating with sulphuric and then adding a little nitric acid.

In Filhol's process this iodine is utilized by liberating it by means of chlorine and converting it into iodoform. The proportions recommended are two parts of crystallized sodium carbonate, ten of water, and one of alcohol, warmed as before; one part of iodine is added in small portions, and after cooling the crystals are collected. The filtrate is again warmed, two parts sodium carbonate are added, and a rapid current of chlorine gas is passed through the liquid as long as iodoform is separated, which is again collected, while the filtrate may be made to yield a little more iodoform by repeating the treatment. As much as 72 per cent. of crystals may thus be obtained.

Rother (1873) recommended the acidulation of the mother-liquor with hydrochloric acid, the adding of some potassium bichromate to generate chlorine, then of potassium carbonate to render the liquid alkaline, and of some iodine and alcohol, and finally the warming of the mixture. The process will thus be continuous until the accumulation of the salts becomes too great.

The production of iodoform may be explained by the simultaneous formation of potassium iodide, water, and carbonic acid, as follows: $C_2H_6O + 4I_2 + 2KHCO_3$ yields $2CHI_3 + 2KI + 3H_2O + 2CO_2$. The reaction, however, is never so simple, formiate of potassium being perhaps always one of the products, in which case the reaction, according to Liebig, is thus explained: $C_2H_6O + 4I_2 + 6KHCO_3$ yields $CHI_3 + 5KI + KCHO_2 + 5H_2O + 6CO_2$. At the same time other reactions take place, one resulting in the formation of acetic ether, another in the production of ethyl iodide and hydriodic acid; and from great variations of the yield observed it is evident that the result is greatly influenced by the relative proportion of the material and the temperature.

Properties.—Iodoform is in lemon-yellow pearly scale-like crystals, which have a saffron-like odor, and a peculiar sweetish taste. It is insoluble in water, but dissolves readily in alcohol, ether, chloroform, carbon bisulphide, and the fixed and volatile oils. It volatilizes slowly on exposure, fuses at about 115° C. (239° F.), and sublimes partly unaltered, but is mostly decomposed into iodine and hydriodic acid with a residue of glossy charcoal. Heated with water it volatilizes with the vapors without decomposition; but when boiled with potassa solution, a portion of it is decomposed, yielding formiate and iodide of potassium, and when distilled with alcoholic solution of potassa, an oily liquid of an ethereal odor and containing iodine is obtained in the distillate.

The odor of iodoform adheres persistently to the vessels in which preparations of it have been made; it may be removed by solution of potassa, aided by alcohol or boiling water.

Impurities are not likely to be present; the physical properties, and particularly its odor and behavior to solvents, determine the absence of impurities which might result from the process of manufacture. Fixed impurities would be left behind on heating a portion upon platinum foil until the charcoal has been consumed.

Medical Action and Uses.—Given to animals, iodoform occasions a certain degree of hebetude, muscular debility, staggering, and anæsthesia, and, in large doses, muscular rigidity and opisthotonos. Thirty grains were found to be fatal to a guinea-pig, forty-five grains to a rabbit, and sixty grains to a dog of medium size. After death no evidence of irritation is found in the stomach, whose lining membrane, on the contrary, is rather pale. But all the organs exhale the characteristic smell of the medicine. In man, doses of from two to five grains occasion no signs of a caustic operation; but seven or eight grains have caused a decline of the pulse-rate from 72 to 60. Applied to the sound skin and mucous membranes and to ulcers, it is not in the least irritating; on the contrary, it appears to allay all local painful sensations in them, and even blunts common sensibility. Thus it may render the anus so insensible that the passage of the fecal mass will not be perceived. It appears to be eliminated with the breath and all the secretions, and very speedily after its administration.

Directly or indirectly this preparation is stimulant and also anæsthetic. The first successful application of it was for the relief of *pain*, and through that for allaying the congestive and inflammatory processes upon which pain so often depends. This quality was conspicuously displayed in the treatment of *cancer* of the uterus, breast, and other parts; for the progress of the local disease was rendered slower, and the exhaustion of the patient's strength retarded. Indeed, not a few tumors (cancroid), supposed to be cancers, were entirely cured under this treatment. Venereal and all other chronic *ulcers* are most favorably influenced by the application of this substance, the more so in proportion as they are irritable and painful. A solution of one part of iodoform in six or seven of ether is considered by some surgeons preferable to the former agent alone, since it acts in smaller quantity and also as a protective to the sore. Carded cotton thoroughly impregnated with iodoform has also been found very useful for applying the medicine to the nostrils, vagina, and rectum. It promotes the healing of blistered surfaces, and of ulcers left by burns. In some cases of ulcerated fissure of the *anus* it has proved a very useful palliative, as well as in certain hemorrhoidal affections attended with pain in defecation. It may be used with similar effect in *vaginismus*. The gangrenous *vulvitis* which is so common under certain conditions of constitution and recent sickness in hospital practice, is more successfully controlled by powdered iodoform than by any other agent, and in other forms of hospital *gangrene* it is efficacious. The anodyne virtues of iodoform displayed in these affections, as well as in various other painful disorders of the rectum, bladder, and uterus, the mouth and the nasal passages, are also exhibited in some internal disorders, and particularly in those of the stomach. *Gastralgia*, alone or associated with simple *gastric ulcer*, is relieved by it, and sometimes permanently cured. Other *neuralgiæ* have, it is said, been cured by iodoform; but as in every case it was associated with iron, the cure, very probably, was due to the latter medicine. The internal exhibition of the medicine has also been used in the treatment of *syphilis*, particularly when it affected the mouth or throat. But such a method is, in reality, a topical use of the medicine.

Administration.—The *dose* of iodoform internally is from one to three grains, three times a day, in pill. It may be applied topically in powder, the part being previously dried; or, in ointments or suppositories, each application containing at least two grains of iodoform. It may also be used, dissolved in oil or glycerin, as a liniment. The following formulæ have been recommended: ℞. Iodoform, ʒj–ʒiss; Glycerin, fʒxij; Alcohol, fʒiv.—M. ℞. Iodoform, gr. xxx; Alcohol, q. s.; Lard, ℥j.—M. A solution for topical application may be made by dissolving one gramme (15 grs.) of crystallized iodoform in four grammes (60 grs.) of sulphuric ether (60° Baumé).

IPECACUANHA, *U. S.*, *Br.*—IPECACUANHA.

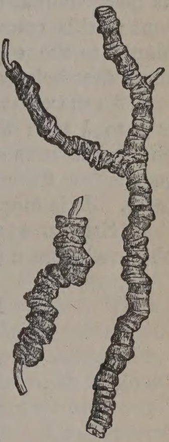
Radix ipecacuanhæ, P. G.—*Ipecac*, E.; *Ipécacuanha*, *Racine brésilienne*, Fr.; *Brechwurzel*, *Ruhrwurzel*, G.

The root of Cephaëlis ipecacuanha, *A. Richard; C.* emetica, *Pers.;* Callicocca ipecacuanha, *Brotero.* Steph. and Church, Med. Bot., plate 62; Woodville, Med. Bot., t. 274; Bentley and Trimen, Med. Plants, 145.

Nat. Ord.—Rubiaceæ, Coffeæ.

Origin.—Two varieties of the plant are known, one with a woody and the other with an herbaceous stem, both being indigenous to the damp forests of Brazil, New Granada, and the northeastern portion of Bolivia, between about 8° and 22° S. lat. The plant has a spreading root, a stem 12 to 18 inches high, opposite, nearly entire, and somewhat hairy leaves, and small white flowers in a dense head, followed by a cluster of dark purplish-blue berry-like fruits, each containing two plano-convex hard nuts. The plant has been introduced into India, and is cultivated to some extent in Sikkim with but moderate success. In Brazil the roots are collected at all seasons, but principally from January to March; they are dug up by means of a stick and pulling the stems, fragments of the roots remaining, which again produce plants. The roots are dried in the sun, and finally packed in bales. About 15,000 pounds are annually imported into the United States.

Fig. 93.



Ipecacuanha.

Description.—The young, thin, and thread-like roots are rejected; the older roots are in pieces of three to five inches in length, and about one-sixth of an inch thick; are mostly simple, bent, and contorted, and consist of a thin, toughish, white, and finely porous ligneous cord, with indistinct medullary rays, and of a thick bark, which is finely wrinkled and closely annulated by projecting circles, the depressions between the rings being often fissured to the wood. The root breaks with a granular and waxy fracture in the brittle bark, which constitutes 75 to 80 per cent. of the weight, and is easily separable from the wood. The color is usually of a dull gray, but occasionally of a reddish or blackish tint. A variety imported from Carthagena is usually thicker, about a quarter of an inch in diameter, less conspicuously annulated, and with distinct medullary rays. Small portions of the thin non-annulated stem are not unfrequently found attached to some of the commercial roots. The odor of ipecacuanha is slight, but heavy and nauseous, and the taste bitterish, somewhat acrid, and nauseating. The root yields a light brown-gray powder.

Constituents.—The common constituents of the root are starch, gum, pectin, sugar, a little fat, and a trace of volatile oil; the important principle is the alkaloid *emetia* or *emetina*, which is combined with *ipecacuanhic acid.* Emetia was discovered in 1817 by Pelletier and Magendie, and is obtained by evaporating the alcoholic tincture of the root to a syrupy consistence, adding potassa in excess and in a well-filled bottle, to prevent access of air, and agitating with chloroform; the chloroformic solution is evaporated, the residue treated with a weak acid, filtered from the resinous matter, and precipitated by ammonia. It is a grayish or whitish inodorous powder, having a bitter taste and an alkaline reaction to test-paper. It is sparingly soluble in cold water, freely so in alcohol and chloroform, slightly soluble in ether and fixed oils. Nitric acid yields with it a slightly soluble brown salt; other dilute acids dissolve it readily, and yield non-crystallizable salts, the solutions of which are precipitated by the general reagents for alkaloids, and by potassium nitrate at 70° C. (158° F.). Emetia fuses like wax, and at a higher heat burns without leaving a residue. Its formula, according to Lefort (1869), is $C_{30}H_{44}N_2O_8$; the yield is little over 1 per cent. By titration with Mayer's solution Zenoffsky (1872) found 3.75 per cent of emetia; much larger yields have occasionally been reported, but are probably over-estimated. Power (1877) observed that emetia is colored bright-yellow or orange by chlorinated lime; a little acetic acid favors the reaction.

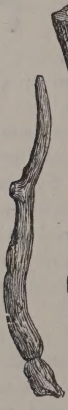
Ipecacuanhic acid, $C_{14}H_{18}O_7$, was, by former investigators, supposed to be identical with gallic acid. Willigk separated it from the precipitate obtained in the decoction by lead acetate, by dissolving in acetic acid and precipitating with subacetate of lead. It is amorphous, brown, very bitter, hygroscopic, soluble in alcohol, little so in ether, colors ferric salts green, and is a glucoside. It appears to be related to caffeo-tannic acid.

Substitutions.—Besides small portions of the stem, the commercial root is usually free from impurities; but several emetic roots known in South America as ipecacuanha, or by the Brazilian designation *poaya*, have occasionally been sent to this country as substitutes; none, however, have any particular resemblance to the cephaëlis root. The following, of which the plants yielding the three first belong to the natural order of Rubiaceæ, are the most important:—

1. STRIATED IPECACUANHA, from Psychotria (Ronobea, *Rich.*) emetica, *Mutis*, is $\frac{1}{4}$ to $\frac{1}{3}$ inch thick, blackish-gray, longitudinally striate; the bark has deep circular fissures at irregular distances, is thick, internally purplish-brown. The root is free from starch, contains much sugar, and has a sweet, afterwards bitter taste. It is employed in New Granada and Peru.

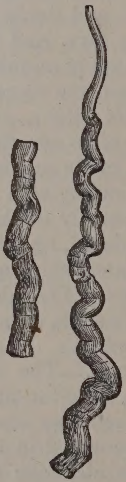
2. SMALL STRIATED IPECACUANHA, noticed by Planchon (1872), probably obtained from a species of *Richardsonia*, resembles the preceding, but is much smaller and only $\frac{1}{12}$ to $\frac{1}{10}$ inch thick, gray-brown, finely striate, has a thick porous wood, and contains starch.

Fig. 94.



Striated Ipecacuanha.

Fig. 95.



Undulated Ipecacuanha.

3. UNDULATED OR FARINACEOUS IPECACUANHA, from Richardsonia scabra, *Lin.*, a native of Brazil, is, in the fresh state, white, when dry, brownish externally and white farinaceous internally; it is irregular undulate, fissured on alternate sides, and of a somewhat knotty appearance.

4. White ligneous ipecacuanha, from Ionidium ipecacuanha, *Vent.*, *Nat. Ord.* Violaceæ, indigenous to Brazil. The root is several inches long, about $\frac{1}{4}$ inch thick, several-headed, somewhat tortuous, not annulate, light gray or yellowish, internally whitish, and with a yellowish wood.

5. Bastard ipecacuanha, from Asclepias currasavica, *Lin.*, *Nat. Ord.* Asclepiadaceæ, indigenous to the West Indies and South America. It has a very short root-stock, which is abruptly divided into numerous thin, pale yellowish-brown, and internally whitish rootlets. It is used in the West Indies like ipecacuanha.

6. Indian ipecacuanha, from Tylophora (Asclepias, *Lin.*) asthmatica, *Wight and Arn.*, *Nat. Ord.* Asclepiadaceæ (Bentley and Trimen, Med. Plants, 177). The root-stock is short, knotty, about $\frac{1}{8}$ inch thick, emitting a considerable number of thin, wiry, brittle, and pale yellowish-brown rootlets.

Off. Prep.—Extract. ipecacuanhæ fluid., *U. S.;* Pilula conii comp., Pilula ipecac. cum scilla, *Br.;* Pulvis ipecac. comp., *U. S.*, *Br.;* Syrup. ipecac., *U. S.;* Trochisci ipecac., Trochisci morphiæ et ipecac., Vinum ipecacuanhæ, *U. S.*, *Br.*

Emetinum coloratum, which is sometimes used in Europe, is made by exhausting ipecacuanha with alcohol, evaporating the tincture to a syrupy consistence, diluting with water, filtering, evaporating the filtrate to dryness, and powdering.

Physiological Action.—Pure emetia is a powerful local irritant, occasioning inflammation and even ulceration of the tissues to which it is applied. Powdered ipecacuanha produces similar but less intense lesions. Friction of the skin with an ointment containing either substance excites, sooner or later, a pustular eruption like that produced by tartar emetic. Two grains of pure emetia suffice to kill a dog. In less toxical doses, it occasions vomiting, great depression of muscular power and of temperature, and diminished frequency and tension of the pulse. After death, the mucous membrane of the stomach and bowels is, according to some, injected, and according to others, pale. These varying results appear to occur whether the poison be given by the stomach, rectum, or veins, or even hypodermically. Moreover, if long continued by either mode of administration, it occasions ulcers of the stomach and small intestine, which are limited to the mucous glands of these organs, and hence are attributed to the elimination of the poison through the glands. The balance of opinion is in favor of the view that nausea and vomiting from ipecacuanha are due to its action upon the nervous centres, and not to its influence upon the gastric terminations of the pneumogastric nerve. Other experiments appear to favor the belief that ipecacuanha excites the brochial secretions, and, in poisonous doses, causes pulmonary congestion. Rutherford and Vignal found that sixty grains of powdered ipecacuanha, mixed with a small quantity of bile and placed in the duodenum, powerfully stimulated the liver; but, owing to the admixture of bile with the drug, this experiment was inconclusive.

In man, the effluvium or dust of ipecacuanha is apt to occasion coryza, and congestion of the larynx and bronchia, causing dyspnœa, cough, and sometimes the rejection of fibrinous sputa. Some persons have a special susceptibility to these effects. In exceptional cases, the conjunctival inflammation reaches a high grade, and is accompanied by neuralgia of the face and scalp. Internally, and in small and repeated doses, ipecacuanha occasions malaise, depression, yawning, salivation, eructation, and nausea, with retching or vomiting. Its emetic operation is not protracted and distressing like that of tartar emetic; but it tends to relax the bowels, if they were previously normal, and to augment the purgative action of cathartics.

Like many other medicines, ipecacuanha in repeated doses, sooner or later, brings about toleration, and produces very different effects from the primary emetic phenomena. But the dose of ipecacuanha is not, at any time, a sure criterion of the effects to be expected from it. Often, four or five grains of it will vomit as much as twelve grains; and while one-tenth of a grain of emetia given to an adult occasioned vomiting, in another case twelve grains were administered within twenty-four hours without exciting either vomiting or diarrhœa. Allowance must be made for the varying degrees of activity of the preparations employed, as well as for the state of the patients who received them.

Medical Uses.—Although the experimental investigations above referred to indicate very little action of ipecacuanha upon the lungs, it is in affections of these organs that the medicine has been so generally employed, that it has come to be classed among *expectorants*. The conditions to which it is appropriate are dryness of the respiratory mucous membrane on the one hand, and excessive secretion or obstruction upon the other. Its mode of action in the two cases is different; in the former, given in small doses, it promotes the bronchial and laryngeal secretions, and thereby renders the cough less painful and frequent, and more productive; in the latter, administered in large doses, it acts as an emetic, producing an expulsion of the contents of the air tubes, while it renders their secretions less tenacious. It is in the former of these ways that it is so efficient in the commencement of the attacks referred to; and in the latter when the bronchia become filled with mucus, serum, or fibrin, as in *whooping cough*, *suffocative catarrh*, *capillary* and *chronic bronchitis*, *bronchorrhœa*, etc. In addition, perhaps, to these two modes of action, a third or antispasmodic action may be recognized in its cure of *spasmodic croup* (spasmodic laryngitis); but quite as probably the relaxation of spasm it occasions is secondary to its sedative, and therefore, so far as the local disorder is concerned, depletory action. A similar operation, no doubt, explains the reputation of the medicine in *spasmodic asthma*. In *membranous croup* it is not without utility in virtue of the same influences, which, however, are inadequate to the occasion. It is far more efficient in the several diseases mentioned, when they occur in children than in adults. The utility of ipecacuanha in *pneumonia*, which has been affirmed, is probably limited to two occasions, the forming, or congestive, stage of the disease, before solidification has taken place, and the declining stage, when the bronchia are apt to become obstructed with softened exudation matter and mucus. In both conditions the emetic action of the drug is appropriate.

Whether by direct stimulation, or by indirectly promoting secretion, there is no doubt that this medicine has proved advantageous in *atonic dyspepsia*, that is to say, when digestion is laborious, painful, attended with flatulence, depression of spirits, cold extremities, etc. The *dose* should not exceed one grain, in pilular form, and may be taken in the morning fasting, or else immediately after meals. The *vomiting of pregnancy* is sometimes arrested by hourly doses of a single drop of wine of ipecacuanha. We have known it to arrest this symptom, in a single day, after it had continued for several weeks.

The title, *radix antidysenterica*, originally applied to ipecacuanha, denotes the estimate then held of its dominant virtue. In Brazil it was the specific for dysentery, and its mode of administration was such as to produce vomiting first, and afterwards tolerance of the medicine. The efficiency of such a method is intelligible in a country where dysentery is apt to assume a bilious type, and an analogy with it is found in a like treatment of the acute febrile diseases of hot climates which is everywhere adopted. In the present instance, antibilious and antipyretic virtues were united in the same remedy. Other forms of acute dysentery than the bilious are not always as advantageously treated by ipecacuanha, and where in such forms the medicine has appeared to be most useful it was usually combined with opium, whose share in the cure should not be overlooked. Of whatever type the dysentery may be, the remedy is most efficient the nearer to the commencement of the attack it is administered. It ought to be given on an empty stomach, and no liquid should be taken for an hour or two after it is swallowed, the patient meanwhile keeping as still as possible. The original Brazilian method of administration was as follows: An infusion was made with 120 grains of the bruised root in six ounces of boiling water, and allowed to stand for twelve hours before the decanted liquid was used. A similar quantity of fresh water was then added to the dregs, for the second day; and the same process was repeated on the third day. Each infusion was divided into two or more portions, one of which was given at intervals of two or three hours if the attack was mild, but both at one dose if the attack was severe. If vomiting occurred, the medicine was, after an interval, repeated. There can be no doubt that when it operates favorably the stools soon lose their dysenteric character and are voided without pain. In Peru it has been the custom to administer the powdered root mixed with a little syrup, and, at the same time, enemas made with an infusion of the root with the addition of laudanum. The enema has been found by many practitioners, in Europe and elsewhere, to be sufficient by itself, when prepared in the following manner: "Take of bruised ipecacuanha 150 grains, and boil it in five fluidounces of water for ten minutes; strain off the liquid and repeat the operation with a fresh portion of water a second and a third time; mix the three portions of liquid and evaporate them in a sand-bath to four ounces; divide this product into two equal parts, and administer one night and morning by enema, directing them to be retained as long as possible." (*Polichronie.*) A simpler, and, apparently, as efficient a formula, is to boil sixty grains of bruised ipecacuanha for ten minutes in five ounces of water; let it infuse for one or two hours, and strain off the decoction. It is only in chronic cases with decided ulceration that any nausea is excited by these enemas. The advantages claimed for the treatment of acute dysentery by ipecacuanha are, the simplicity, safety, and promptness of its operation, its efficiency in curing, and the rapidity of the cure. Even in *chronic dysentery* the same method of employing it has been very successful.

The medicine has long been used in the treatment of *chronic diarrhœa*, either alone or associated with calomel and opium. Of late it has been administered alone, or guarded with opium to prevent its rejection, in *infantile diarrhœa*, in *tuberculous diarrhœa*, and in chronic *dyspeptic diarrhœa*. Of these forms, the one most beneficially influenced by the medicine is the infantile. If the patient is not much exhausted, the medicine may be given at first by the mouth, otherwise by enema, and in the form of infusion. The diarrhœa of consumption, being due sometimes to intestinal ulcers, and sometimes to debility, as well as in both cases to the swallowing of sputa, the results of any treatment must vary with the cause of the symptom. In this case the utility of the medicine is least when the cause is most permanent. If it is too long employed it may create an irritation as great as that which it is fitted to relieve. Whether it acts by substitution, or astringency, or as a stimulant of the vaso-motor nerves, it very certainly diminishes the secretions of the affected part, and apparently does so during its elimination after absorption. The same mode of operation is probable in the case of *hectic sweats*, which are sometimes completely suspended by enemas of ipecacuanha infusion, when other remedies have proved ineffectual. The treatment of *cholera morbus* and of *epidemic cholera* by this medicine has been advocated by numerous physicians who presented ingenious reasons for its use; but neither their opinion nor their practice has prevailed.

The utility of ipecacuanha emetics in *hemorrhage* from the lungs, stomach, uterus, etc., has long been known, but more recently the use of repeated small doses of the medicine, without vomiting, has been very successful in such cases. Probably in hæmoptysis and hæmatemesis a full emetic dose should be first prescribed, after which smaller and only nauseating doses may be substituted. According to the modern views of the action of the medicine, it may be supposed to control hemorrhage by contracting the capillaries, but the earlier explanation, that the heart was depressed and the blood no longer circulated so vigorously, should not be lost sight of.

In bilious *remittent* and *intermittent fevers*, when gastro-hepatic congestion is indicated by the muddy eye and skin, the foul tongue, nausea, bitter taste, distended epigastrium and hypochondria, and, perhaps, bilious vomiting and diarrhœa, an emetic dose of ipecacuanha promptly palliates these symptoms, and renders the action of quinia more immediate and certain. Ordinary *intermittent fever* is alleged to have been cured by doses of one or two grains every three or four hours. In all cases of *indigestion* due to the presence of food in the stomach, of *urticaria* produced by the same cause, and of *poisoning* where it is desired to expel the offending substance, ipecacuanha emetics may be advantageously employed.

As a local application to the eye in purulent *ophthalmia*, when the active inflammatory symptoms have subsided, but chemosis remains with a red and flabby state of the conjunctiva and cloudiness of the cornea, a decoction of ipecacuanha has been found efficient. It may be made by boiling thirty grains of bruised ipecacuanha for ten minutes in five ounces of water. When cool the liquid should be strained off and instilled into the eye.

Administration.—As an emetic, the *dose* of powdered ipecacuanha is twenty grains, or five or ten grains may be repeated every ten minutes, the patient drinking freely of warm chamomile tea, or simply of warm water, as soon as the first signs of nausea appear. Or an *infusion*, prepared with 120 grains of the bruised root in six fluidounces of boiling water, may be given in doses of a fluidounce at intervals of four or five minutes. A *decoction* and its uses have been already described. As a *nauseant*, one or two grains of the powder may be repeated at short intervals; the same *dose*, at longer intervals, may be used as a diaphoretic and expectorant. For infants the syrup is preferable.

IRIS FLORENTINA, *U. S.*—FLORENTINE ORRIS.

Rhizoma iridis, P. G.; *Radix iridis Florentinæ*, *Radix ireos*.—*Orris root*, E.; *Iris de Florence*, Fr.; *Veilchenwurzel*, G.

The rhizome of Iris Florentina, *Lin.* Stephenson and Church, Med. Bot. I. t. 27; Bentley and Trimen, 273.

Nat. Ord.—Iridaceæ.

Origin.—Florentine orris or *white flag* is found in dry localities from the southern shores of the Black Sea westward along the north shore of the Mediterranean; though wild near Florence and Lucca, Hanbury does not regard it as indigenous to these places. It has large sweet-scented white flowers, the sepals with a yellow beard and brownish veins. It is cultivated together with Iris pallida, *Lam.*, which is likewise indigenous to Southern and Southeastern Europe, has a rather tall stem, and pale-blue or purplish flowers, and with Iris germanica, *Lin.*, which is indigenous to Southern and Central Europe, and is met with in Northern Africa and Northern India; it has a lower stem, bears deep-blue or purplish-blue flowers, and it is known in England as *blue flag*. The rhizomes of the three species are collected, and, as it appears, those of the last two much more frequently than of the first. They resemble each other very closely, and, though the branches of the second species are usually broad and stout, there are no permanent characters by which they may be distinguished. The rhizomes are collected in the latter part of summer, peeled, and dried in the sun. 28,000 pounds of orris root reach the United States annually.

Description.—The horizontal rhizome is composed of joints, which are 2 to 4 inches long, the broadest part near the apex about an inch wide, tapering below, and abruptly narrowed above to the circular stem-scar, from two sides of which similar joints are produced. The rhizome is vertically compressed, and, when peeled, of a white or whitish color externally and internally. The leaf-scars on the upper side are indicated by the transverse lines of vascular bundles, and the rootlets on the lower surface by circular brownish scars, which are more crowded near the upper end. The texture is firm, the rhizome breaking irregularly, and shows upon the transverse fracture, near the surface and parallel with it, a distinct nucleus sheath inclosing a number of scattered wood-bundles. Orris root has an agreeable violet-like odor, which is slowly developed on drying, and a mealy, afterwards bitterish and somewhat acrid, taste. The powder has a whitish color.

Constituents.—Orris root contains a minute quantity of volatile oil, which is solid, crystalline, and of a pearly lustre, as described by Dumas (1835). By distillation with steam, a solid crystallizable substance is obtained which Flückiger found to consist mainly of *myristic acid* impregnated with a little volatile oil; this acid, however, does not pre-exist in the rhizome. This constitutes the commercial *oil of orris root;* but a *liquid oil of orris* has recently appeared in the market, which is said to be made by adding oil of cedar-wood to the crushed rhizome, and distilling the mixture with water. Orris root contains also a large quantity of starch in very small granules, some soft brownish resin of an acrid taste, and a little tannin which colors ferric salts green.

Adulterations.—The rhizomes of other species of Iris in most cases resemble the officinal one in shape, but are destitute of its agreeable odor; those of *Iris pseudacorus*, Lin., and *I. fœtidissima*, Lin., which are indigenous to Europe, have a darker color and a more astringent and acrid taste. The adulteration of powdered orris is best detected by the microscope, from the different shape of the starch-granules contained in the material employed for the purpose.

Medical Action and Uses.—The fresh root is said to possess irritant properties, and, taken internally, to cause colic, vomiting, and purging, while the dry root acts as a moderate digestive stimulant. When powdered and applied to the nostrils it excites sneezing and increased secretion, and in the mouth a flow of saliva. It is asserted that when freely sprinkled in the hair it has caused alarming nervous symptoms. It was formerly used along with more active medicines in the treatment of *chronic diarrhœa* and *bronchitis*, and also as a diuretic and sternutatory. A piece of the root was, and occasionally is still, employed for children to bite upon while teething; it probably excites salivation and mitigates the pain of the process. Iris is also used to make issue "peas," is often added to dentifrices on account of its aromatic flavor and its favorable action on the gums, and is an ingredient in *pastilles* used for the same purpose, or to conceal fetor of the breath. Its liability to be attacked by insects renders care in its use as an issue "pea" desirable.

IRIS VERSICOLOR, *U. S.*—BLUE FLAG.

Rhizome d'iris varié, Glaïeul bleu, Fr.; *Verschiedenfarbige Schwertlilie*, G.

The rhizome of Iris versicolor, *Lin.* *Nat. Ord.*—Iridaceæ.

Origin.—The blue flag is common in wet and swampy meadows of Canada and the United States, and flowers in the latter part of spring. The sword-shaped leaves are about as long as the stout stem, which bears a few showy blue flowers, having the three outer lobes of the corolla with a yellow blue-veined base, and the inner lobes paler.

Description.—The rhizome is horizontal, and like the preceding grows in annual shoots or joints, bearing a flowering stem at their end, and producing two or often four lateral branches. The joints are 2 to 4 inches long, cylindrical at the base, the upper portion vertically flattened and $\frac{3}{4}$ to 1 inch broad; they have an annulated appearance from the projecting leaf-scars, and at the lower side are beset with simple rootlets, 4 to 6 inches long, and somewhat crowded near the broader end of the joint. The color of the fresh rhizome is yellowish-brown, when dry gray-brown, and internally gray or brownish. Nucleus sheath, and arrangement of wood-bundles are as in the preceding. The dry rhizome has no marked odor; its taste is acrid and nauseous.

Constituents.—The rhizome contains starch, tannin, and acrid resinous matter; the latter may probably represent its medicinal virtues. An analysis, however, is very desirable.

Medical Action and Uses.—The fresh root has an acrid taste, and its expressed juice is emetic and cathartic, and produces great prostration. Diuretic and cholagogue virtues are also ascribed to it. It was a medicine highly esteemed by the aborigines of this country. Its activity appears to depend upon its oleoresin, which may be used as a purgative in the dose of one or two grains. The *dose* of the dried root is stated to be from ten to twenty grains.

JALAPA, *U. S.*, *Br.*—JALAP.

Tuber jalapæ, P. G.; *Radix jalapæ.*—*Jalap*, Fr.; *Jalape*, *Jalapenknollen*, G.

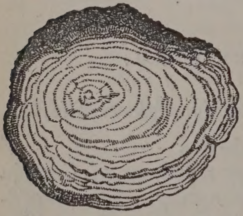
The tuber (tubercules) of Exogonium purga, *Bentham*, Bot. Mag., vol. lxxiii. plate 4280. (Ipomœa purga, *Hayne;* Convolvulus purga, *Wender.;* C. jalapa, *Schiede;* Ipomœa schiedeana, *Zucc.;* Ipom. jalapa, *Nutt.*)

Nat. Ord.—Convolvulaceæ.

Origin and Collection.—This twining herbaceous perennial is indigenous to the damp and shady woods on the eastern slope of the Mexican Andes at an altitude of from 5000 to 8000 feet. It has been introduced into India, and flourishes well in the Nilgherry Mountains. It has alternate cordate leaves, acute at the apex and the basal lobes, and axillary cymes of 3 to 5 dark pink-colored flowers, with a long tube, spreading border, and protruding stamens. The tubers (hypertrophied roots, *Bentley*) are collected during the whole year, but principally in the spring. Owing to the wet climate the drying cannot be effected by exposure to the sun, but is accomplished by suspending the tubers in a net over a wood fire; the smaller pieces are dried entire; the larger ones are incised to facilitate the drying. The supply of jalap is very variable.

Description.—Jalap, when fully developed, is napiform or depressed globose in shape, above marked by the scar of the overground stem, below suddenly contracted into a thin root. The tubers are often pyriform, ovate, oblong, or nearly cylindrical in shape, and vary in size from that of a walnut to 3 or 4 inches in diameter. They are externally of a dark brown color, and usually of a smoky appearance, more or less longitudinally wrinkled, and beset with brown broad corky warts, becoming transversely confluent. Jalap is hard and tough, and breaks irregularly; the transverse fracture is not fibrous, and shows a distinct concentric arrangement. The bark is quite thin, gray-brown, with a large number of resin cells, forming a dense zone near the cambium line. The central portion of jalap resembles the bark, except that the resin cells are arranged in concentric circles, which vary in width, a zone of 3 or 4 rows of resin cells, usually alternating with one of a single row. Jalap has a very faint radiate appearance, the fibro-vascular bundles being small and not very numerous. It has a slight smoky and sweetish odor, and a sweetish afterwards acrid taste. Good jalap should not be deeply wrinkled or sticky externally, but should be plump, heavy and hard, and when fractured should present a resinous appearance.

Fig. 96.



Transverse section of Jalap.

Impurities and Substitutions.—Jalap appears to be sometimes collected in an immature state or at an improper season; at least many of the tubers frequently contain little resin, but otherwise present all the characteristics of genuine jalap. Occasionally jalap has been met with which has been previously deprived of the resin, and is then sticky upon the surface, and of a dark color internally. A *mealy jalap* has been observed, which resembles true jalap externally but has few scattered resin cells and a mealy fracture. The so-called *jalap stalks, male, fusiform or woody jalap*, consist of the tuberous root of Ipomœa orizabensis, *Pelletan*, often cut into transverse slices 2 to 3 inches broad, light brown and more fibrous in texture; it is spindle-shaped, 2 feet long, and contains resin which is entirely soluble in ether. *Tampico jalap*, from Ipomœa simulans, *Hanb.*, forms globular or elongated tuberous pieces, which are often smaller, but occasionally larger than true jalap, deeply wrinkled, and destitute of transverse scars: the resin contained in it is completely soluble in ether.

The tuberous root of Mirabilis jalapa, *Lin.*, or Four-o'clock, resembles jalap somewhat in shape, but is darker externally, and contains a large number of acicular crystals.

Radix mechoacannæ, probably obtained from a convolvulacea, is found always in sections, of a whitish or gray color, destitute of resinous circles; it cannot be mistaken for jalap.

Constituents.—Jalap contains starch, gum, sugar, and extractive matter; its medicinally important constituent, however, is *resin*, of which selected pieces may contain 22 per cent., but which varies in good commercial jalap between 12 and 18 per cent. About $\frac{1}{12}$ or $\frac{1}{10}$ of the resin is soluble in ether, of a brown color, acid reaction and acrid taste; it is soluble in alkalies, and reprecipitated from these solutions by acids. It is contained in the officinal resin of jalap, the main constituent of which is the resin insoluble in ether; this, investigated by Kayser (1844), was named *rhodeoretin*, and by W. Mayer (1852), *convolvulin*. When pure it is colorless, transparent in thin layers, inodorous and tasteless; it consists of $C_{62}H_{100}O_{32}$, dissolves readily in caustic alkalies, and is not reprecipitated by acids, but converted into *convolvulic acid*, $C_{62}H_{106}O_{35}$, of which convolvulin is the anhydrid. Both are glucosides, and when boiled with dilute acids, yield sugar and *convolvulinol*, $C_{26}H_{50}O_7$, which crystallizes in needles, is bitter and acrid, and when treated with alkalies, loses water, and is converted into *convolvulinolic acid*, $C_{26}H_{48}O_6$. Convolvulin and its derivatives, on being oxidized with nitric acid, are finally converted into oxalic and *ipomic acids*, the latter being $C_{10}H_{18}O_4$.

W. Mayer (1855) has very improperly given the name of *jalapin* to the resin obtained from orizaba root, which with all its derivitives is homologous to the preceding. *Jalapin*, $C_{68}H_{112}O_{32}$, closely resembles convolvulin, but is soluble in ether. Dissolved in alkalies it is converted into *jalapic acid*, $C_{68}H_{118}O_{35}$, which is soluble in water; when treated with dilute acids, into sugar and *jalapinol*, $C_{32}H_{62}O_7$, which is acrid, and with alkalies yields *jalapinolic acid*, $C_{32}H_{60}O_6$. Nitric acid oxidizes these compounds to oxalic and ipomic acids. Spirgatis (1860) considers jalapin chemically identical with *scammonin*.

The resin of the tampico root is likewise homologous. Spirgatis (1870) calls it *tampicin*, $C_{68}H_{108}O_{28}$, which yields with alkalies *tampicic acid*, $C_{68}H_{120}O_{34}$, and with diluted acids sugar and *tampicolic acid*, $C_{32}H_{64}O_6$.

Allied Plants.—Of the numerous species of Ipomœa which have been used like jalap, we mention the following in addition to those named above:—

I. pandurata, *Meyer*, s. Convolvulus panduratus, *Lin.*, grows in sandy banks in the United States, and is known by its pointed, heart-shaped leaves, which are sometimes contracted near the middle, and fiddle-shaped. The root is elongated, cylindrical, two or three feet long, one to several inches thick, abruptly contracted above to the thickness of a finger. It is pale-brownish externally, grayish-white internally, and emits, when wounded, a resinous milk juice. It is known as *manroot*, *man of the earth*, *wild jalap*, and *wild potato*, and is feebly cathartic.

I. turpethum, *R. Br.*, *Turpeth root*, is indigenous to India and the East Indian Islands. The root is met with in commerce in pieces of various length, ½ to 1 inch thick, frequently with pieces of the woody stem attached, reddish-brown externally, internally grayish or brownish. The bark is thick, mealy, and contains numerous small brown resin cells in concentric rows, and several, or in older roots numerous woody groups. The central wood is pale brown, porous, and divided by narrow medullary rays into four or six parts. The resin, *turpethin*, $C_{34}H_{56}O_{16}$, is insoluble in ether, and resembles jalap resin in its behavior to alkalies and dilute acids.

I. nil, *Roth*, s. Convolvulus (Pharbitis, *Choisy*) nil, *Lin.*, is indigenous to the tropics, and grows spontaneously in the Southern United States. The seeds are about ¼ inch long, black, somewhat triangular, rounded on the back, of a rather heavy odor while fresh, and of a sweetish, afterwards acrid taste. The seeds, which contain a fixed oil and resin, are known in India as *kaladana*, and roasted or in powder, are used as a purgative, like but somewhat weaker than jalap.

Off. Prep.—Extract. jalapæ, Pulv. jalapæ comp., *U. S.*, *Br.*; Pulv. scammonii comp., *Br.*; Resina jalapæ, Tinctura jalapæ, *U. S.*, *Br.*

Medical Action and Uses.—Jalap, and its resinous principle, convolvulin, act as local irritants, and, taken into the stomach, produce irritation of that organ, with nausea, vomiting, colic, and mucous, watery, and even bloody dejections, according to the dose. When given to dogs in excessive doses it may occasion death, after which the gastro-intestinal mucous membrane has been found inflamed. Although it is said to produce analogous effects in these animals when rubbed into the skin, it is, on the other hand, denied that this effect takes place in man, and affirmed that the milk of nursing women is not rendered purgative by its use. So, too, convolvulin, which purges if taken into the stomach, has no such effect when it is injected into a vein, or hypodermically. Its special virtues depend upon its being a hydragogue cathartic, whose operation is not rendered less decided by the repetition of the medicine. Hence it is profitably employed for the removal of *dropsical effusions*, from whatever cause they arise, the permanence of its usefulness depending upon the organic cause of the dropsy. It is usually associated with bitartrate of potassium for this purpose; and with calomel in congested states of the liver or spleen. It is to be commended in states of *constipation* attended with habitual dryness of the intestine, when it should be given in a dose of two or three grains in the morning fasting, and followed within an hour with a draught of cool water. A grain or two of aloes the night before renders its operation more certain, and is apt to promote the biliary secretion. It is not an anthelmintic, but a *vermifuge*, and is associated habitually with proper vermicide medicines.

Administration.—The dose of jalap is from fifteen to twenty grains. Its powder should be thoroughly triturated with sugar flavored with an aromatic oil. The resin is estimated to be from two to four times as strong as jalap. The syrup of rhubarb is said to completely dissolve it, and to increase its efficiency.

JEFFERSONIA.—TWINLEAF.

Jeffersonia diphylla, *Barton*. *Nat. Ord.*—Berberidaceæ.

Origin.—The twinleaf is an herbaceous, acaulescent perennial, growing in woods in the Middle, Southern, and Western United States. The leaves are on long petioles, composed of two obliquely ovate leaflets: the scape is about 10 inches high, bearing a white flower an inch broad, which has 4 fugacious sepals, 8 spreading petals, and 8 stamens, and produces an obovate capsule with many seeds. It flowers in April and May.

Description.—The rhizome is horizontal, knotty, beset with long, fibrous, and matted roots of a yellowish or dark-brown color, somewhat corrugated, and transversely fissured; the bark is brown, of a resinous appearance, and has a bitter and acrid taste. The pale-yellowish wood is destitute of taste.

Constituents.—The rhizome was analyzed by E. S. Wayne (1855), and contains, besides the ordinary vegetable principles, tannin, precipitating ferric salts dark-green, a bitter principle and an acrid acid analogous to polygalic acid. F. F. Mayer (1863) states that the rhizome contains a small quantity of *berberina*, a larger proportion of a *white alkaloid*, and a considerable amount of *saponin*.

Medical Action and Uses.—No recent observations seem to have been made of the virtues of this plant. It is said to be diuretic, tonic, and expectorant in small, and emetic in large doses. It has been compared to seneka.

JUGLANS, *U. S.*—BUTTERNUT BARK.

Écorce de noyer gris, Fr.; *Graue Wallnussrinde*, G.

The inner bark of the root of Juglans cinerea, *Lin.* (J. cathartica, *Mich.*; J. oblonga, *Mill.*) Bentley and Trimen, Med. Plants, 247.

Nat. Ord.—Juglandaceæ.

Origin.—A handsome tree, thirty to forty feet high, growing in forests and bottom lands in Canada and the greater portion of the United States. The leaves are composed of about fifteen sessile oblong-lanceolate, serrate, and underneath pubescent leaflets; the staminate flowers are in aments about four inches long; the pistillate flowers, to the number of about five, form a spike; the fruit is ovoid-oblong and viscid pubescent. The tree flowers in April and May, and ripens its fruit in September and October. The bark is collected in May and June, and is deprived of its corky layer.

Description.—The liber of which the medicinal article exclusively consists is white when fresh, but rapidly turns yellow and deep brown. The outer surface has often thin patches of cork adhering; the inner surface is smooth and striate. The tangential arrangement of the brownish bast fibres alternating with the white parenchyma, and crossed by the numerous fine white medullary rays, gives the cross section a delicately checkered appearance. The bark breaks readily with a short fracture both transversely and longitudinally. It has a feeble odor and a bitter, somewhat acrid taste. If collected in April it has a sweetish, insipid taste, and is said to be less active.

Constituents.—The bark has been examined by Thiebaud (1872), and by Dawson (1874). The latter found a little tannin, trace of volatile oil, a little resin, and 14 per cent. of fixed oil; also a volatile acid, called by Thiebaud *juglandic acid*, but which is doubtless identical with the *nucin* of Reischauer and Vogel (1856), discovered by them in the pericarp and leaves of *Juglans regia*, Lin. Nucin has an acrid taste, an acid reaction to test-paper, and is sparingly soluble in water, more so in alcohol, and readily so in ether; it crystallizes as orange-yellow needles, and acquires, with alkalies and with the alkaline borates and phosphates, a handsome purple color. If the properties of the bark depend wholly or in part on this principle, it is easily explained why continued boiling should render it less efficacious.

The green pericarp and the leaves of *Juglans cinerea*, Lin., or English walnut, have been used for similar purposes. The young fruit of both species is used for pickles, and when ripe their kernels yield a bland and drying fixed oil, known as *nut oil;* it is greenish or pale yellow, congeals like lard at about —18° C. (0° F.), and acquires a red color with nitric acid, and a dark-brown one with a mixture of nitric and sulphuric acids.

Off. Prep.—Extractum juglandis, *U. S.*

Medical Uses.—It is employed medicinally in the form of the officinal extract alone.

JUJUBA.—JUJUBE BERRIES.

Jujube, Fr.; *Brustbeeren*, *Judendornbeeren*, G.

The fruit of Zizyphus vulgaris, *Lin.*, and Z. lotus, *Lam.*

Nat. Ord.—Rhamnaceæ.

Origin.—The jujube shrubs are indigenous, the former to Asia Minor and Syria, the latter to Northern Africa, and are cultivated in Southern Europe. They are shrubby, or sometimes tree-like, and have alternate ovate and serrate three-nerved leaves at the base, with two prickly, afterwards spiny stipules. The fruit is a two-celled and two-seeded, or by abortion one-celled and one-seeded, drupe.

Description.—Jujubes are nearly an inch long, bright-red, or after drying brownish-red, wrinkled, with a thin leathery pericarp, a soft mucilaginous and sweet sarcocarp, and an ovate, acute, wrinkled, and usually one-seeded endocarp. The fruit of the second species is about one-half the size of the first.

The fruits of Ziz. jujuba, *Lam.*, a slender East Indian tree, and of several other species, possess similar properties.

Constituents.—Jujubes contain mucilage and sugar. The bark contains tannin.

Pharmaceutical Uses.—MASSA DE JUJUBIS, Jujube paste, *E.*, Pâte de jujubes, *Fr.*, is prepared by extracting 5 parts of jujubes in sufficient water to obtain 35 parts of infusion, in which are dissolved gum arabic 30 parts and sugar 20 parts; the solution is evaporated, 2 parts of orange-flower water added, kept slowly boiling for twelve hours, and then poured into moulds. *F. P.* In the jujube paste, as sold in the United States, the jujubes are usually omitted.

Medical Action and Uses.—In the native countries of the jujube its fruit is ranked with figs and raisins and other more or less saccharine and acidulous fruits, which are used in tisanes for acute irritations of the throat and air-passages, much as in this country we employ the syrup and jelly of currants, blackberries, etc. The so-called jujube paste seldom contains any of the fruit, but is made of gum arabic and sugar with some flavoring ingredient and a variable proportion of opium.

JUNIPERUS, *U. S.*—JUNIPER.

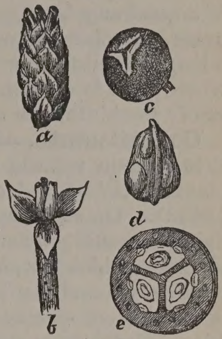
Fructus juniperi, P. G.; *Baccæ juniperi.*—*Juniper berries*, E.; *Genièvre*, *Fruits* (*Baies*) *de genièvre*, Fr.; *Wachholderbeeren*, G.

The fruit of Juniperus communis, *Lin.* Woodville, Med. Bot., t. 6; Bentley and Trimen, Med. Plants, 255.

Nat. Ord.—Coniferæ, Cuppresseæ.

Origin.—Juniper is indigenous to the northern hemisphere, and is found in North America from the Southern United States to Canada and Greenland, and westward to the Pacific, throughout Asia from the Himalayas northward, in Northern Africa, and throughout Europe. It is commonly a shrub four to six feet high, sometimes arborescent, or, in the variety *alpina* (*Jun. nana*, Willd.), prostrate and spreading, the latter being met with in arctic and mountainous localities. The numerous leaves are persistent, spreading, in whorls of three, linear and sharp-pointed; the staminate flowers are arranged in short ovate catkins; the pistillate form a short cone consisting of about five imbricate whorls, each of three scales. Three naked ovules are situated at the base of the upper whorl, and after fructification, these scales enlarge, coalesce, become fleshy and ultimately inclose the seeds, forming the officinal berry-like galbulus, which ripens during the second year.

Fig. 97.



Juniperus communis, *Lin.*—*a*, fertile catkin; *b*, the same deprived of lower scales; *c*, galbulus; *d*, seed (magnified) with oil glands; *e*, transverse section of galbulus.

Description.—Juniper berries are nearly globular, about one-third of an inch in diameter, dark-purplish, and covered with a whitish bloom; the short stalk at the base contains one or two whorls of the small scales, and the apex is marked by three radiating furrows, which are surrounded by ridges inclosing a triangular space. The three bony seeds are ovate in shape, triangular above, have six to ten large oil sacs on their surface, and are imbedded in a brownish pulp which likewise contains oil cells. Juniper berries have an aromatic, somewhat balsamic odor, and a sweet, terebinthinate, bitterish, and slightly acrid taste. The trade is mostly supplied from Southern and Central Europe.

Constituents.—Juniper berries were analyzed by Trommsdorff (1822), Nicolet (1831), Steer (1856), and Donath (1873). They contain from ½ to 2½ per cent. of volatile oil, about 30 per cent. of sugar, resins amounting to 10 per cent., 4 of protein compounds, fat, wax, formic and acetic acids, malates, and *juniperin*, which is light-yellow, slightly soluble in water, freely so in alcohol and ether, and with a golden-yellow color in ammonia.

Other Products of Juniper.—*Juniper wood, lignum juniperi*, is used in Europe as an alterative and diaphoretic in diseases of the skin and rheumatic affections. The resinous exudation found in the bark, *resina juniperi*, is sometimes called *German sandarac.* (See also Oleum juniperi.)

Off. Prep.—Infusum juniperi, *U. S.*

Medical Action and Uses.—Juniper is stimulant, stomachic, carminative, diuretic, and emmenagogue. It communicates a special odor to the urine. It is much used in the treatment of *dropsies*, and especially of scarlatinous and other forms of dropsy due to tubular obstruction of the kidneys. (Juniperi contus., Potassii bitart., āā ℥ss; Aquæ fervent., Oj. Make an infusion, to be used in divided doses, during twenty-four hours. Acetate of potassium may be substituted for the bitartrate in this formula, but in half the quantity. The diuretic virtues of the infusion may be increased by the addition of parsley, buchu, horse-radish, etc.) In chronic catarrhal affections of the *urinary passages* juniper is sometimes useful, and also when sabulous matter is habitually voided. As an anodyne for painful *swellings*, and generally for *local pains*, bruised juniper berries are sometimes used, and fumigations made by throwing the berries upon hot coals may be employed to relieve rheumatic pains.

JUNIPERUS VIRGINIANA, *U. S.*—Red Cedar.

Cèdre de Virginie, Fr.; *Virginische Ceder, Rothe Ceder*, G.

The tops of Juniperus virginiana, *Lin.* *Nat. Ord.*—Coniferæ, Cuppresseæ.

Origin.—Red cedar is shrubby or is more frequently a tree 50 or sometimes 90 feet high, growing in sterile or rocky soil in Canada and the United States, south to the Mexican Gulf and westward to the Pacific. It has a compact, reddish, and odorous wood, horizontal branches, the older leaves spreading and awl-shaped; the young leaves appressed and imbricate, and a small non-pendulous fruit. The young branches, on which the leaves are still appressed, are collected for medicinal purposes.

Description.—The branchlets resemble savine, are about one inch long, and of a quadrangular appearance from their four rows of scale-like leaves, which are ovate lanceolate, obtuse, or rather acute, appressed, and imbricated. They have a longitudinal furrow on the back, which gradually deepens towards the base, where there is contained a circular or oblong gland. They have a not unpleasantly terebinthinate odor, and an aromatic bitterish and somewhat acrid taste.

Constituents.—Red cedar was analyzed by W. J. Jenks (1842) who found it to contain volatile oil, resin, fat, tannin, and other common constituents of plants. *Oil of red cedar*, distilled from the wood, was examined by Walter (1842). On exposing it to cold, expressing the congealed mass, and recrystallizing the solid portion from alcohol, *cedren camphor*, $C_{15}H_{26}O$ (*Gerhardt*), was obtained, which has an aromatic odor and a slight taste. The liquid portion, after rectification and distillation over potassium, is *cedren*, $C_{15}H_{24}$ (*Gerhardt*), which is colorless, of specific gravity 0.98, boils at 237° C. (458.6° F.), has an aromatic odor differing from that of the camphor, and an aromatic afterwards pepper-like taste.

Medical Action and Uses.—The leaves of red cedar are said to possess in a less degree the qualities of savine, but definite information upon the subject is wanting, so far as their internal operation is concerned. An ointment prepared with them is employed as a dressing to maintain the discharge of suppurating surfaces. An infusion of the berries is reported to be diuretic; and the small, gall-like excrescences found on the branches are eaten as an anthelmintic medicine.

KALMIA.—MOUNTAIN LAUREL.

Calico-bush, *Spoonwood*, E.; *Kalmie*, Fr., G.

The leaves of Kalmia latifolia, *Lin.* *Nat. Ord.*—Ericaceæ, Ericineæ.

Origin.—This shrub is found in Canada and the United States, west to Ohio and Kentucky, and is abundant in many places, preferring woods on rocky hills and damp soil. It is usually about 6 feet high, but sometimes tree-like and 15 or 20 feet high. The elegant but inodorous flowers appear in May and June, are in dense racemose corymbs, and have a rose-red or whitish subcampanulate corolla, which, in its lower part, is furnished with 10 cavities, holding the 10 anthers until they begin to shed their pollen. The Indians are said to have made spoons from the wood.

Description.—The leaves are alternate, two or three inches long, petiolate, coriaceous, oval-lanceolate or elliptic, entire, acute at both ends, smooth and green on both sides. They are without odor, and have an astringent and bitterish taste.

Constituents.—Chas. Bullock (1848) proved the leaves to contain tannin, a principle resembling mannit, an acrid principle, resin, gum, and other common constituents of plants. Kennedy (1875) isolated *arbutin*, which appears to be present in smaller proportion than in uva ursi.

Allied Plants.—KALMIA ANGUSTIFOLIA, *Lin.*, known as *sheep-laurel*, *sheep-poison*, and *lamb-kill*, has opposite or ternate linear-elliptic leaves, which are 1 or 2 inches long and whitish or brownish beneath. The small flowers are of a deep crimson color.

KALMIA GLAUCA, *Ait.*, *Swamp-laurel*, has pale purple flowers and subsessile lanceolate leaves, which are glaucous beneath, about an inch long, and opposite on the two-edged branches.

ANDROMEDA MARIANA, *Lin.*, or *stagger-bush*, is likewise reported to be poisonous to lambs and calves. It is a shrub 2 or 3 feet high, produces clusters of white, nodding, ovate-cylindrical flowers, and has thick, but deciduous, smooth, oval or oblong, entire leaves, about 2 inches long.

OXYDENDRUM ARBOREUM, *D. C.*, s. Andromeda arborea, *Lin.*, *sorrel tree*, or *sourwood*, is about 40 feet high. The leaves are deciduous, oblong-lanceolate, pointed serrulate on the margin, and nearly smooth. They resemble peach leaves in shape, and have a refreshing acidulous taste.

All the species named above belong to North America.

Medical Action and Uses.—The leaves and berries of the mountain laurel have long been known to be poisonous; but their action has chiefly been learned through the effects produced in man by eating the flesh of partridges (*Tetrao umbellus*) that have fed upon the berries. From a number of cases observed or collected by Dr. Jacob Bigelow, he prepared (1857) the following summary of the symptoms of this poisoning. The flesh of the bird "acts as a direct sedative poison, impairing the functions of the brain, and, in connection, those of the digestive and circulating systems. The cerebral symptoms, in a majority of the cases, have been vertigo, loss of sight, tinnitus aurium, and in bad cases general loss of the power of sensation and voluntary motion. Respiration has been slow, sometimes to a great degree. In the circulating system there has been syncope, feeble and sometimes irregular action of the heart; weak, slow, and sometimes imperceptible pulse; cold surface, and pale or livid complexion. In the digestive system there are oppression, nausea with a tendency to vomit, and in many cases pain in the abdomen extending through to the back. In more rare cases pain has been felt in the head and limbs. . . . The poison of the partridge has never, to my knowledge, proved fatal." One of the most recent cases was published by Dr. Homans in 1871, and answers trait for trait to the summary given above. The connection of these symptoms with laurel poisoning has been questioned, and they have been attributed to the partial putrefaction of the bird's meat when it was eaten. But as they are identical with the effects observed by Stabler in himself after taking a strong decoction of laurel leaves, there need be no doubt of their having been referred to their true source. The medicinal value of this plant is almost entirely conjectural. The bruised leaves and also a decoction are said to have been applied to certain cutaneous eruptions, and it is added that alarming symptoms have sometimes resulted, probably because the skin was not whole. It might be profitable to test their efficacy in neuralgic and other local pains, by applying them in the same manner.

KAMALA, *Br.* See ROTTLERA.

KINO, *U. S.*, *Br.*—KINO.

Gummi (s. Resina) Kino.—*Kino*, Fr., G.

The inspissated juice, obtained from incisions made in the trunk of Pterocarpus marsupium, *D. C.* (*Roxb. Corom.*, plate 116; Bentley and Trimen, Med. Plants, 81), and of other plants.

Nat. Ord.—Leguminosæ, Papilionaceæ.

Origin.—The kino tree, called *buja* in Bengal, is about 60 feet high, has numerous spreading branches, a red inner bark, unequally pinnate deciduous leaves, yellowish flowers in loose racemes, and nearly orbicular and winged pods, which contain a single kidney-shaped seed. It is indigenous to India and Ceylon, and, on incisions being made through the bark, yields a red juice, which is dried by exposure to the air and sun. Some kino is also yielded by *Pter. indicus*, Willd., a native of Southern India.

Description.—East India or Malabar kino is met with in small, angular, dark-red, glistening, and brittle pieces, which in thin layers are transparent, and of a ruby-red color; it softens between the teeth, is inodorous, and has a very astringent and sweetish taste. It is partly soluble in water, leaving a flocculent residue, entirely soluble in alcohol, and insoluble in ether.

Constituents.—By treating kino with ether, Eissfeldt (1854) obtained a minute quantity of *pyrocatechin*. The products of the dry distillation of kino contain a larger quantity of the same substance, which may be obtained pure by subliming in a benzoic acid apparatus. Kino contains no *catechuic acid*, but its tannin, *kino-tannic acid*, seems to be chemically related to the former, since it yields similar decomposition products; but it has not yet been obtained in a pure condition, being accompanied by red coloring matter, and according to Hennig (1853) by a pectin compound, from which it cannot easily be freed. The aqueous solution of the acid gives with pure ferrous salts when carefully neutralized a violet color, and with ferric salts a blackish-green one. Mineral acids and many metallic salts produce precipitates; hot nitric acid converts it into oxalic acid. In solution it is darkened by alkalies; and when treated with fusing potassa it is decomposed into *protocatechuic acid* and *phloroglucin*. On exposure to air, the aqueous solution yields a red precipitate, slowly at the ordinary, more rapidly at the boiling temperature; this is *kino red*, an amorphous, tasteless mass, the alcoholic solution of which has a slight acid reaction. Kino yields about 1.3 per cent. of ash.

Other varieties of Kino.—AFRICAN or GAMBIA KINO exudes naturally from Pteroc. erinaceus, *Poir.*, of Western Africa, and agrees with the Bengal kino in behavior; it is not an article of commerce.

AUSTRALIAN or BOTANY BAY KINO is usually referred to Eucalyptus resinifera, *Smith* (Myrtaceæ); but F. von Mueller sent exudations from sixteen different species to Wiesner (1871), who found the products of E. rostrata, *Schlech.*, E. corymbosa, *Sm.*, E. piperita, *Sm.*, and of some others to agree well with Malabar kino, while the exudation of E. resinifera, E. gigantea, *Hook.*, and others, contains much gum, which is colored red by a kino-like substance. A kino-like substance is occasionally obtained from E. globulus, *Lab.*

BENGAL or PALAS KINO; *Butea gum*, from Butea frondosa, *Roxb.* (*Leguminosæ*), is in dark ruby-colored tears and fragments, of which only about one-half is soluble in hot alcohol; it yields about 1.8 per cent. of ash.

JAMAICA, WEST INDIAN, or CARACAS KINO, from Coccoloba uvifera, *Lin.*, or *sea-side grape* (*Polygonaceæ*), is obtained by boiling the wood and bark, and evaporating the decoction. It resembles Malabar kino in appearance, but is of a more brownish tint, less glossy, and has a bitterish rather than a sweetish taste; it is soluble in both alcohol and water to the extent of about 90 or 93 per cent. The tannin of this kino seems to be closely related to, if not identical with, that of the officinal article.

Off. Prep.—Pulv. catechu comp., Pulv. kino comp., *Br.;* Tinctura kino, *U. S.*, *Br.*

Medical Action and Uses.—This astringent is more lenitive than other medicines of the same class, in consequence, probably, of the pectin it contains. Its modified astringency renders it in some degree a local tonic. It is chiefly used in the treatment of *diarrhœa*, and of that form of gastric disorder known as *pyrosis*. In the former it may be profitably employed when pure astringents would be too irritating, and generally associated with opium, as it also should be in the treatment of water-brash. It has sometimes been given with apparent advantage to check *sweating* in phthisis, urination in *diabetes*, and bleeding in *menorrhagia*. Its solution may be used as an injection in diarrhœa, *dysentery*, and *leucorrhœa;* as a dressing for flabby *ulcers*, and as a gargle in ulcerated *sore throat.* In powder it has been employed as a *hæmostatic.* But as a local application it is inferior to other astringents, and especially to tannin.

Kino may be prescribed in powder in the *dose* of from ten to twenty grains. An infusion may be made with one hundred and twenty grains of kino in eight fluidounces of boiling water. When cool, it should be strained, and given in doses of one or two tablespoonfuls. Owing to the tendency of its gummy matter to coagulate, it is less eligible than catechu as an ingredient of the chalk mixture.

KRAMERIA, *U. S.*—RHATANY.

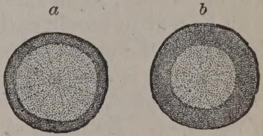
Krameriæ radix, Br.; *Radix ratanhæ*, P. G.; *Radix ratanhiæ.*—*Rhatany root*, E.; *Ratanhia*, Fr.; *Ratanhawurzel*, G.

The root of Krameria triandra, *Ruiz and Pavon, Flor. Peruv.* Steph. and Church, Med. Bot., plate 72; Bentley and Trimen, Med. Plants, 30.

Nat. Ord.—Polygalaceæ, Kramerieæ.

Origin.—The *ratanhia* is a low shrub with spreading branches, a native of Bolivia and Peru, and grows in sandy localities in the mountains at an altitude of 3000 to 8000 feet; it has a striking appearance from the leaves, which are densely covered with silvery hairs, and from the flowers, which have four scarlet sepals arranged in the form of a cross, and four small dissimilar red petals.

Fig. 98.



Transverse section of—*a*, officinal; *b*, Savanilla rhatany root.

Description.—The root has several knotty heads, and consists of a woody main root, which is 1 or $1\frac{1}{2}$ inch thick, and from 2 to 4 inches long, when it divides into several spreading and bent branches, 10 to 18 inches long, and varying in thickness from $\frac{1}{8}$ to $\frac{1}{2}$ inch. The latter constitute what is sometimes called *long rhatany*, while the less desirable heads and main root are called *short* or *stumpy rhatany.* The bark is smooth, or in the older roots scaly; of a peculiar rust-brown, or blackish-brown color; somewhat resinous in the outer, and rather fibrous and brownish-red in the inner, layer. The wood is from six to ten times thicker than the bark, of a pale brownish or reddish color, radially striate by numerous fine medullary rays, very tough, and nearly tasteless. The bark, like the wood, is inodorous, but has a strongly astringent taste, which accounts for the superiority of the *long* root.

Constituents.—The most important constituent is *ratanhia-tannic acid*, which has been investigated by Wittstein (1854). It is precipitated dark-green by ferric salts, and flesh-colored by gelatin, but not precipitated by tartar emetic. Grabowski (1867) observed that by fusion with potassa it is decomposed into *protocatechuic acid* and *phloroglucin;* and that the *ratanhia-red* of Wittstein, which is obtained by boiling with dilute sulphuric acid, has the same composition, $C_{26}H_{22}O_{11}$, as the similar product obtained by Rochleder (1866) from the tannin of the horsechestnut, and by Rembold (1868) from that of tormentil. The tannins obtained from the three plants appear to have the composition $C_{26}H_{24}O_{11}$. The other constituents of rhatany root are wax, gum, and uncrystallizable sugar.

From an extract of rhatany formerly exported from South America, Wittstein isolated a crystalline body which he regarded as identical with *tyrosin*, but which Städeler and Ruge (1862) found to be $C_{10}H_{13}NO_3$; they named it *ratanhin.* Gintl (1869) proved it to be identical with the *angelina* of Peckolt, obtained from the *resina d'angelim pedra*, the exudation of *Ferreira spectabilis*, Allem., and suggested that some kino-like extracts from this and allied plants had been used as substitutes or adulterations of the extract of rhatany.

Other Rhatany Roots have occasionally appeared in commerce.

PARA OR BRAZILIAN RHATANY was described by Berg (1865), and by J. G. S. Cotton (1868), in two varieties, as *Ratanhia des Antilles.* It has a dark-brown or blackish bark, which adheres more firmly to the wood, and is longitudinally striate or transversely fissured, and without a fibrous fracture. Flückiger and Hanbury refer it to Krameria argentea, *Mart.*

SAVANILLA OR NEW GRANADA RHATANY is obtained from Kram. tomentosa, *St. Hil.*, which Cotton proved to be identical with Kr. grandifolia, *Berg*, and Kr. ixina β. granatensis, *Triana.* It resembles the Peruvian rhatany, but is always less knotty, and more slender; its bark has a distinct purplish hue, is smooth or longitudinally striate externally; the wood is only three or four times thicker than the bark, the tannin of which appears to differ somewhat from that of the officinal variety.

TEXAS RHATANY has been described by Berg; it is derived from Kr. secundiflora, *D. C.*, and consists of a roundish root stock, about two inches thick, from which a number of long roots emanate, which have a blackish-brown, internally reddish bark of the same thickness as the wood.

Off. Prep.—Extract. krameriæ, *U. S.*, *Br.;* Extr. krameriæ fluid., *U. S.;* Infusum krameriæ, *U. S.*, *Br.;* Pulv. catechu comp., *Br.;* Syrup. krameriæ, *U. S.;* Tinct. krameriæ, *U. S.*, *Br.*

Medical Action and Uses.—In small doses slightly tonic, in larger doses astringent, in still larger doses rhatany causes dyspeptic uneasiness and oppression, with constipation, effects probably due to its astringent qualities. It has been chiefly employed to restrain *hemorrhages* of every variety, but is most efficient in those of the passive sort, and particularly in that form of uterine hemorrhage in which the flow, without being profuse, is habitual. It is not without utility, as an internal medicine, in *uterine leucorrhœa.* It may be used with benefit in atonic and chronic *diarrhœa*, and in *incontinence of urine* from debility of the urinary organs.

Locally it is applied by injection to the treatment of *dysentery*, vaginal *leucorrhœa*, and *gleet*, and has enjoyed considerable reputation as a remedy for *fissure of the anus.* Its mode of action is thought to consist partly in constringing the walls of the rectum, and thereby preventing the formation there of a large fecal mass, which tends to exaggerate the fissure, and render defecation more painful. But it appears also to promote directly the healing of the fissures by limiting the amount of blood that reaches them. The mode of using the remedy consists merely in emptying the rectum with an emollient enema, and half an hour later throwing into the bowel a solution of sixty or ninety grains of extract of rhatany in five ounces of water. This operation is repeated night and morning, and on both occasions the enema is retained only for a few moments; or else it is allowed to run out at once, and is again thrown into the bowel; and this process is renewed for several minutes at a time. The bowels are meanwhile prevented from becoming confined by the use of appropriate food, or of gentle laxatives, such as sulphur, cassia, etc.; or, as has been especially recommended, the administration of powdered belladonna root, in the dose of a grain or less, given at night. The administration of the enemas, which is painful at first, gradually and indeed rapidly ceases to be so, and, if steadily persevered in, is usually successful in effecting a cure.

A watery solution of rhatany, or its extract, is of service in the treatment of *fissured nipples.* A mixture of the extract with white of egg may also be employed. The part should be cleansed when the child nurses, which ought to be as seldom as possible. In non-syphilitic *ozæna* an infusion of rhatany is sometimes serviceable, introdued into the nostrils with a sponge, or injected with a nasal douche, several times a day. The addition of chlorinated soda is advantageous; or chloride of lime may be added to the infusion in the proportion of from five to ten grains to the ounce of liquid, which, after standing for a time, should be strained.

Administration.—Powdered rhatany is seldom employed; the infusion, extract, tincture, and syrup are officinal.

LABDANUM.—LABDANUM.

Resina ladanum.—Labdanum, Ladanum, E., Fr., G.

A resinous exudation of Cistus creticus, *Lin.;* C. cypricus, *Lam.;* C. ladaniferus, *Lin.*, and of other species of Cistus. Bentley and Trimen, Med. Plants, 24.

Nat. Ord.—Cistaceæ.

Collection.—The resinous exudation of these handsome shrubs, indigenous to Greece and the Levant, is collected during hot weather by means of the *labdanisterion*, consisting of a wooden handle, with many narrow leather bands on one end, which are drawn over the branches, the resin being afterwards scraped off, and often kneaded together with sand and other material. An inferior kind is obtained from the wool and hairs of sheep and goats, which feed on the plants, either by combing or after shearing, by boiling with water.

Description.—Labdanum is met with in two forms, either as blackish or dark-brown masses, which soften and become glutinous in the hands, and are gray upon the fresh fracture, the color soon becoming darker. Or it is seen in cylindrical rolls, about the thickness of a finger, and rolled spirally into flat pieces. Sometimes it is also in cylindrical sticks, somewhat of the shape of liquorice. Good labdanum is insoluble in water, almost completely soluble in alcohol, fusible, burns, when ignited, with a bright flame, and has an agreeable, balsamic odor, and a bitter taste. The roll and stick labdanum are frequently adulterated or artificially made.

Constituents.—According to Guibourt, cake labdanum contains 86 per cent. of resin and volatile oil, 7 of wax, 1 of extractive matter, and 6 per cent. of insoluble impurities. Pelletier found in roll labdanum only 20 per cent. of resin and 72 per cent. of sand.

Medical Action and Uses.—The singularly grateful odor of this resin led to its being used in the most ancient times for the fumigation of rooms and clothing, and as a medicine both internally and externally for the same purposes as other articles of the same class. It was used internally and through its fumes for chronic bronchitis, and locally in leucorrhœa and other uterine affections; it was also prized as a diuretic. Later it was an ingredient of various stimulant plasters. Its use is now obsolete.

LABURNUM.—LABURNUM.

Golden-chain, Bean-trefoil, E.; *Faux ébénier, Cytise*, Fr.; *Goldregen*, G.

Cytisus laburnum, *Lin.* *Nat. Ord.*—Leguminosæ, Papilionaceæ.

Description.—This is a tall shrub or low tree, indigenous to Southern Europe and planted in this country for ornament. It grows to the height of 15 or 20 feet, and has a smooth bark. The *leaves* are on slender petioles, trifoliate, with nearly sessile oval-oblong, obtuse, and mucronate leaflets, which are about two inches long, smooth, and dark-green above, soft hairy and grayish beneath; they have a somewhat saline, bitterish, and slightly acrid taste. The golden-yellow *flowers* are in long hanging racemes, and produce linear, obtuse legumes containing dark-brown nearly reniform *seeds* of a disagreeable bitter and acrid taste.

Constituents.—Chevalier and Lassaigne obtained the bitter principle of the ripe seed in an amorphous condition and named it *citysin.* T. Scott Gray (1862) obtained, in addition thereto, *laburnic acid* and two neutral bitter principles, *cystin* and *laburnin,* which are present chiefly in the seed and bark. The *citysina* of Husemann and Marmé (1865) is a white crystallizable alkaloid, of a bitterish taste and strong alkaline reaction, easily soluble in water and alcohol, but nearly insoluble in ether, chloroform, benzol, and carbon bisulphide. Its composition is $C_{20}H_{27}N_3O$. The leaves contain only traces of it; it is likewise found in the seeds of other species of cytisus.

Physiological Action. *On Animals.*—According to Dr. T. S. Gray, who elaborately investigated the composition of this drug and its operation, its effects upon dogs, cats, and rabbits are nearly identical. The decoction, however administered, is apt to cause vomiting, and also languor and muscular relaxation, the breathing and pulse-rate are accelerated, and there is always a greater or less tendency to sleep, which, however, is never comatose or profound. No irritant effects due to laburnum or any of its constituents are found after death. After fatal doses vomiting first takes place, and then, after more or less of the symptoms before enumerated, but with spasm rather than resolution, death follows gradually, the heart continuing to pulsate until the end. After death the brain and spinal cord are engorged, as are also the veins of the right side of the heart, but the lungs are collapsed, and the left side of the heart is empty. Cytisine, laburnine, and laburnic acid, considered as separate active elements of laburnum, appear to act in very nearly the same manner.

On Man.—In medicinal doses it induces a slight degree of languor and tendency to sleep, rather confines than relaxes the bowels, and very slightly, if at all, increases the urinary secretion. Larger doses are very apt to produce a slightly soporific effect, and are very sure to excite vomiting and sometimes purging, as well as some quickness of the pulse and giddiness. The same effects are induced by cytisine, and each of the other alleged proximate principles appears to cause some drowsiness and contraction of the pupils. In cases of poisoning by the bark or berries, and which have been very numerous in Europe, the effects observed are remarkably uniform. They comprise the following phenomena: Vomiting, pain in the stomach which is sometimes excruciating; purging; dryness, heat, and constriction of the throat; faintness, languor, vertigo, drowsiness, or a narcotic sleep with slow and stertorous breathing followed by insomnia; the eyes are dull and sunken, the pupils dilated, and the eyelids dusky; the pulse is very weak or fluttering, varying between 90 and 100; thirst is usually marked, and in the worst cases muscular twitchings of the neck and face are observed. No headache or other pain, except that in the stomach, is complained of, nor do general convulsions occur. In no case has death been observed.

Medical Uses.—Laburnum has been recommended by Dr. Gray in *bilious dyspepsia* with periodical attacks of bilious vomiting, diarrhœa, and constipation in the intervals. It should be taken in small doses which do not sicken the patient, thrice daily before meals, and continued for six or eight weeks. He also regards it as efficient in cases of children who *vomit* after eating, as a palliative of *whooping-cough,* of the *nausea* and sickness of pregnancy, of *asthma* connected with emphysema of the lungs, etc. These recommendations have not, as yet, been confirmed by experience. The author of these statements proposes for use a decoction of laburnum concentrated until it attains a specific gravity of 1.034, to be given in *doses* of from two to forty minims. The *dose* of the extract is stated to be from one-tenth of a grain to one grain; of cystinia, from half a grain to four grains; of laburnic acid, from one to six grains; and of laburnine, from five to twelve grains.

In cases of poisoning the stomach should be evacuated by warm water, and ammonia and alcohol administered internally.

LAC, *Br.*—MILK.

Lac vaccinum.—*Lait*, Fr.; *Milch*, E.

The fresh milk of the cow, Bos taurus, *Lin.*

Class Mammalia. *Order* Ruminantia.

Description.—Cows' milk is an opaque white liquid having a slight peculiar odor and a bland and sweet taste; its specific gravity is about 1.030. Viewed under the microscope it is seen to be a clear and transparent liquid in which a large number of minute globules are suspended. On standing, these rise to the surface as a yellowish stratum, the *cream*, which constitutes about 5.0 per cent. of the milk, and consists mainly of fat mixed with some casein and retaining some serum. By churning the globules unite to form *butter*, and the liquid which separates and is known as *buttermilk* is essentially a solution of *milk sugar* and the saline constituents of milk, and contains some casein and butter. The milk from which the cream has been separated is called *skimmed milk.* If left to itself, it becomes acid and separates the casein in a coagulated condition called *curds;* the same effect is produced by rennet and by acids. The liquid separated from the coagulum is called *whey*, and contains chiefly milk sugar and some salts.

Constituents.—The chemical constituents of the milk of mammals are qualitatively alike, but quantitatively vary very much for different species, for different individuals, and even for the same individual, depending in the latter case upon the length of time since the last birth, upon the kind and quantity of food, and upon the exertion or rest of the individual. The following table is compiled from the averages given by Lehman and others (*Physiol. Chemistry*):—

	MILK OF—					
	Woman.	Cow.	Mare.	Goat.	Sheep.	Sow.
Albumenoids (protein compounds)	2.5	4.1	1.7	5.0	4.5	6.2
Fat (butter)	3.6	4.0	0.8	3.7	4.2	5.8
Milk sugar	6.5	4.2	8.8	4.5	5.0	5.3
Salts (chiefly phosphates)	0.5	0.7	0.4	0.6	0.7	0.9
Total solids	13.1	13.0	11.7	13.8	14.4	18.2
Water	86.9	87.0	88.3	86.2	85.6	81.8

The albumenoids consist of *casein* and *lactoprotein.* Casein is not coagulated by heat, but on evaparating its aqueous solution it becomes insoluble and separates in the form of a thin skin; acetic and other acids coagulate it; so does rennet, and after this ceases to have any further effect, acetic acid will produce another coagulation. The protein compounds of the different milks, however, vary slightly in their behavior to some reagents.

Butter, as obtained by the churning of cream, is a very complex mixture of fats with small quantities of an odorous principle, casein, milk sugar, salts, and water; the fats are glycerides of butyric, capronic, caprinic, myristic, palmitic, stearic, and oleic acids, some of which are gradually decomposed, whereby the liquid fatty acids are liberated and the butter turns *rancid.*

As stated above, milk left to itself becomes acid; the change takes place in consequence of the fermentation of milk sugar (see Saccharum lactis) induced by the casein, whereby *lactic acid* is generated. The change is prevented, for some time at least, by the addition of certain compounds, for which purpose borax has been recommended; but boric acid in the proportion of 1 to 1000 milk, as recommended by Hirschberg (1871), is preferable as not altering the taste. Salicylic acid (1 to about 5000 milk) has also been found serviceable. If kept in vessels closed by Appert's method, it separates into several strata, but remains unchanged. More recently, however, *concentrated* or *condensed milk* has been introduced, which is simply fresh milk mixed with a certain proportion of sugar, evaporated at a low temperature to the consistence of a thick syrup or soft extract, in which condition it will keep well.

Adulteration.—When milk is mixed with water, its specific gravity is lowered; skim-milk, on the other hand, has a higher density. To detect adulterations, the quantity of the solids is determined by evaporation to dryness; from this the amount of fat is ascertained by treating with ether or petroleum benzin, and the residue is either incinerated to determine the amount of mineral constituents and estimate the albuminoids and sugar combined by the loss in weight; or the residue isoluble in ether is treated with alcohol and water, which leave casein, and dissolve the sugar and salts. Since the milk residue is dried and afterwards exhausted, some chemists prefer to evaporate the milk mixed with a known quantity of dry sand, calcium sulphate, or similar material.

Various instruments, called *lactometers*, have been constructed with the view of ascertaining rapidly the purity of milk, by determining either the density, the degree of opacity, the percentage of cream, or the amount of butter.

Pharmaceutical Uses.—Milk is used in preparing Mistura scammonii, *Br.*, and in the preparation of wheys, which are officinal in several European Pharmacopœias.

SERUM LACTIS, *P. G.;* SERUM LACTIS DULCE.—Whey, *E.;* Petit-lait, *Fr.;* Molken, *G.* Take of fresh cows' milk 200 parts, rennet wine 1 part, mix and warm to 35° or 40° C. (95° or 104° F.), and after coagulation strain from the curd.

SERUM LACTIS ACIDUM, *P. G.*, s. Serum lactis, *F. P.*—Acid whey, *E.;* Petit-lait acidue, *Fr.;* Saure Molken, *G.* Heat fresh cows' milk 100 parts to boiling, add 1 part of potassium bitartrate (or 0.1 part of citric acid dissolved in 1 part of water), and when completely coagulated strain.

SERUM LACTIS ALUMINATUM, *P. G.*—Alum whey, *E.;* Petit-lait alumineux, *Fr.;* Alaunmolken, *G.* It is prepared like the preceding, except that 1 part of powdered alum is used to effect the coagulation.

SERUM LACTIS TAMARINDINATUM, *P. G.*—Tamarind whey, *E.;* Petit-lait tamariné, *Fr.;* Tamarinden-Molken, *G.* The coagulation of 100 parts milk is effected with 4 parts of tamarinds, and the strained whey has a brownish color.

Medical History.—In the Hebrew Scriptures milk is constantly referred to for its precious qualities as food, and no more striking figure could be employed to represent the exuberant riches of a country than that it was a "land flowing with milk and honey," that is to say, suitable for raising herds and grain. Milk is the most essential article of food for man before his teeth are matured for mastication; as well as in that second childhood when "the grinders cease because they are few," especially when it is associated with wine, which is "the milk of old age." Not less does it become the essential and most salutary food of man when, at any period of his life, he is enfeebled by disease. The qualities that adapt it to these several states or conditions of life are, the facility of eating it, for it needs no mastication; the rapidity of digesting it, since it needs but little change to convert it into assimilable material; and the small amount of waste which it involves and of digestive power which it requires, since the fecal residue of its digestion is less than from any other food.

The ancients used milk from the cow, the camel, the mare, the ass, the goat, and the sheep, and attributed to several among them special virtues or defects; thus sheep's milk was considered binding, asses and goat's milk rather relaxing, and to cow's milk intermediate qualities were attributed. A full summary of the subject is furnished by Pliny, who represents human milk as the most nutritious and goat's milk next in strength, calling to memory the myth that Jupiter was suckled by a goat. The mildest milk, according to Pliny, is the camel's. He very correctly remarks that crude milk is more flatulent and less wholesome than boiled milk. He states that milk is used for all manner of internal inflammations, including those of the kidneys, bladder, bowels, throat, and lungs; and externally for itching and watery eruptions of the skin, and refers to its use, as Celsus also did, in the cure of phthisis. He speaks of its value in other cachexiæ, and especially of the cure of chronic gout by asses' milk, and also of milk in general in the treatment of dysentery, and of poisoning by colchicum, conium, etc. He refers particularly to asses' milk in marasmus and other wasting diseases, and to the use in affections of the spleen of milk from goats that had fed on ivy. He describes the mode of preparing whey, and its uses in epilepsy, melancholy, paralysis, and diseases of the skin. Milk was also applied topically in ophthalmia, in ulcerations of the mouth, throat, and uterus.

Medical Action and Uses.—The special action of milk considered as a therapeutical agent is that, while it affords sufficient nutriment, it moderates the stimulating action of the blood, and restricts the excrementitious waste derived from the food, thereby enabling the organs which are obstructed by blood, by secretions, or by more or less plastic exudations, to purge themselves of these hindrances to a free and normal action. In a word, it gives rest, which is the primary condition of cure, and removes hindrances to a return of that functional activity which is an essential condition of health. The milk treatment is essentially a "hunger treatment," and is analogous to that natural and instinctive abstinence from food which is observed in all acute febrile diseases, and in the greater number of chronic disorders. It is the cry of nature to be let alone, to be spared that officious assiduity which is as mischievous in dietetics as in medicinal therapeutics. This we conceive to be the simple explanation of the curative powers of milk. Tortured as it may be by physiological experiment, it reveals no special action upon this or that organ or anatomical element, but so modifies the whole system as to restore its soundness without the aid of drugs, or else enables them to produce results which without its aid they would have been unable to accomplish.

Of all forms of food that can be used in *fevers* and *inflammations*, there is no doubt that milk is the best whenever the decline of the fever and the process of wasting have begun. Before this period watery preparations of starchy products, especially of barley and rice, are sufficient; but as soon as tissue waste shows itself, a portion of milk should be added to them and gradually increased until it forms the principal part of the nourishment, or is supplemented by the stimulant operation of beef-tea. In less acute affections and especially in those attended with suppuration, or an excessive discharge of blood, serum, or mucus, nothing so well as milk maintains the strength without tending to excite fever. When in the stomach or bowels inflammatory or ulcerative lesions exist, the use of milk can hardly be dispensed with. In *simple gastric ulcer* it is the one remedy which may be depended upon for a permanent cure; and in *cancer* of the stomach or bowels it is infinitely the best palliative, and the only one by means of which life may with any certainty be prolonged. But in these and similar cases the quality of the milk employed must be carefully adjusted to the tolerance of the digestive organs, and, if necessary, its retention favored and its assimilation promoted by the addition of lime-water, or by preceding the administration of each portion with a dose of bismuth. The same remarks apply to *dysentery*, both in its acute and chronic forms, provided that in the acute disease whey, or milk and water, or buttermilk is employed rather than pure milk. The last is most efficient in the chronic form, if it be administered with due regard to its tolerance by the patient. In not a few cases, *albuminuria* due to desquamative nephritis has been cured by the persistent use of an exclusive milk diet alone, and in others by an association with it of ferruginous-saline mineral waters, or of officinal preparations of iron. Even in those less curable cases of interstitial nephritis associated with hepatic and cardiac lesions, there can be no doubt that this method tends to remove the dropsy, and at the same time quiet the morbid violence of the heart's action, while it greatly improves the nutrition of the system. Some years ago several physicians announced the cure of *diabetes* by a milk diet, but longer observation showed that they must have been deceived, and that the treatment by milk aggravates the disease. In regard to a milk diet in *chronic diseases of the chest*, whether tuberculous or bronchitic with their associated affections pleurisy and emphysema, it suffices to say that, as a rule, it is contraindicated, as affording too little nutriment when there is need of all that can be assimilated. In point of fact a milk diet, as such, never cured or even ameliorated any one of them; but its use has been followed by favorable results, even in consumption, when it has been associated with other favorable hygienic influences, such as a pure, dry atmosphere, active and regular exercise, a complete change in the habits of living, abstention from the use of perturbative drugs, and a nutritious diet fitted to compensate for the defects of the milk regimen in this respect. A milk and vegetable diet has long been used in the treatment of *epilepsy*, and its operation is intelligible by analogy when we consider that every remedy that has been most useful in this disease, from the time of Aretæus, who declared, " From flesh in particular the patient is to be entirely restricted," down to the introduction of the bromides, has been a sedative of the nervous and circulatory systems. Milk is one of the most convenient and efficient antidotes for nearly all corrosive *poisons*, acids, alkalies, and metallic salts, because with some of them it forms compounds that are not readily soluble, and all of them it envelops in its curd and thus tends to prevent a corrosive action or absorption, until proper emetics can be administered. The close analogies of milk and chyle are illustrated by the effects of its injection into the veins, which was tried by Donné in 1842, and without causing any alarming symptoms. Later it was employed, fruitlessly, by Bovell and by Herepath in *cholera*, and about 1860 by Hodder, of Toronto, in a case of complete collapse, in which reaction and recovery followed. Subsequently Dr. Howe and then Dr. Thomas, of New York, made use of the same method, the one in *phthisis*, the other in *traumatic hemorrhage*, and in no case did any alarming symptoms arise when the milk employed was perfectly fresh.

Administration.—According to Karell, a chief apostle of the " milk cure," it is essential that the patient abstain from all other food but milk, and this he must take at fixed hours and in determinate quantities. This milk, we are told, must be skimmed, but that degree of exaction is not required by others who employ the method. It should be warmed, not hot, in winter, cool but not iced in summer, and should be swallowed by small mouthfuls and slowly. If the stools are consistent, the quantity of milk may be gradually increased, until from four to six pints a day are taken. Almost always a primary effect of the treatment is to produce constipation, which must be overcome by a little castor oil or rhubarb, or by a roasted apple or stewed prunes. Sometimes much more energetic modes of treatment are called for. If the patient is thirsty he may drink pure water or carbonated water. Towards the third week of this process, if he grows weary of it he may be allowed a little stale bread once a day, or grits or other analogous preparations may be added to the milk. To carry out this discipline requires the patient to be endowed with a degree of courage approaching heroism; but, in certain cases, it brings a due reward, the flesh and strength, which had before been declining under the combined influence of pain, indigestion, and scanty nourishment, begin to improve, and thus persons of resolution are encouraged to endure their martyrdom and reap its reward.

It may be stated here that *condensed milk* is in many cases a valuable substitute for fresh milk, in all cases of sickness calling for the use of milk, and especially in places where good milk cannot be procured from the cow. This is notoriously the case at most of our sea-side resorts, and it occurs also where the drinking-water is unduly mineralized.

Serum Lactis; *Whey.*—This preparation, which contains little else than sugar of milk and a fractional percentage of salts, and is nutritious chiefly through its watery element, has been used from time immemorial as a drink in fevers. It is agreeable to the taste, or may be rendered so by lemon juice, or by tamarinds, as was the custom in Sydenham's day, and is also more or less diuretic and laxative. Taken copiously and hot, it was at that time the favorite diaphoretic at the commencement of febrile attacks due to cold. When whey is drunk to the extent of a pint or two every day, and for several weeks together, it tends to derange the stomach, impair the appetite, and produce diarrhœa, and is, therefore, improper in all chronic diseases in which the digestive organs are already enfeebled. On the other hand it may, as far as it goes, prove useful in chronic blood disorders like *gout*, *rheumatism*, and *gravel*, with congestion of the brain or of the portal circulation, owing to its depurative and somewhat diuretic qualities. But, in Germany, where alone the "whey-cure" is systematically employed, it is pursued in localities in which pure air and exercise, to say nothing of the mineral waters usually taken at the same time, doubtless have much more to do with the cure of disease than the systematic drinking of whey.

BUTTERMILK, or the thin sour milk separated from the cream by churning, contains caseum, but very little butter. Even by many persons in health it is considered a most refreshing drink, and there is no form of *fever* in which it is not apt to be relished, probably on account of its acidulous taste. It is one of the very best remedies that can be employed in acute and even in chronic *dysentery*, promptly allaying the tenesmus and modifying the bloody mucous stools of the acute form, and lessening the frequency of the evacuations in the chronic disease. Its effects in *typhoid fever* are scarcely less striking. It renders the discharges less numerous, and moderates the tympanites. It should be given in doses of from two to four ounces every three or four hours, and always as fresh as possible.

KOUMISS is a drink imitated from the Tartars, and which may be considered a peculiar form of milk punch, since it contains the saline and protein constituents along with the sugar, fat, and lactic acid of the milk, together with carbonic acid and alcohol, these constituents varying with the length of time employed in the fermentation. It is, therefore, a nourishing and stimulating drink, sometimes even an intoxicating one, since the longer it is kept the more alcohol it contains. One analysis states that at the end of sixteen days it yields upwards of twenty parts of alcohol in a thousand. The effects of drinking two or three glasses of koumiss are identical with those of alcohol: a general diffusive glow, a quickening of the pulse, a pleasurable excitement of mind and body. Like alcohol, indulged in overmuch, it impairs the appetite for food, tends to constipate the bowels, renders one dull and sleepy, and augments the urinary solids. Moderately used, it promotes digestion and nutrition, or at least increases the weight by augmenting the fat, precisely like milk punch. Like that familiar drink, it is of more or less use in various wasting diseases, including consumption and nervous exhaustion. It is not to be wondered at that in Germany a counterfeit koumiss is prepared with milk, lemon, and rum. There is good reason to fear that the general fondness for sparkling wines and other effervescing drinks may tend to render fashionable a draught which, under the disguise of a medicine, partakes more or less of their intoxicating qualities, and may become the prime cause of a baleful habit of intoxication. There is much danger, also, lest its votaries overlook the essential condition of its utility, active exercise in the open air and those other hygienic measures upon which the utility of alcohol and other hydrocarbons in all chronic wasting diseases essentially depends.

LACCA.—LAC.

Resina (*Gummi*) *lacca.*—*Laque, Gomme lacque,* Fr.; *Lack, Gummilack,* G.

A resinous exudation produced by the puncture of Coccus lacca, *Kerr.*

Origin.—The hemipterous insects thus named congregate in large numbers upon the tender branchlets of various East Indian laticiferous trees, and become surrounded with the resinous exudation, which gradually hardens. The impregnated much enlarged female insects, imbedded in the resin, contain a red coloring matter, in which the young larvæ are developed. These finally eat a passage through the incrustating material and escape. The branches are collected with the incrustation, which is considered more valuable if still containing the red coloring matter. Among the trees yielding lac are the following: Aleurites laccifera, *Willd.* (Croton, *Lin.*), *Nat. Ord.* Euphorbiaceæ; Ficus indica, *Roxb.*, F. bengalensis, *Lin.*, F. religiosa, *Lin.*, F. tsjela, *Hamil.*, *Nat. Ord.* Urticaceæ; and several others.

Description.—The thin branches almost completely covered with numerous small resin-nodules constitute the *stick-lac.* The separate nodules or tears are red-brown, and contain in the interior a dark blackish-red powder; after the escape of the young insects, the resin is brown. The same resin, after having been detached from the twigs, constitutes the *seed-lac* or *grain-lac.* It is in irregular fragments, of the size of a pea and smaller, yellowish-brown or reddish, somewhat shiny, and nearly tasteless. After boiling the stick-lac or seed-lac with water, fusing the resin, and congealing it upon a smooth surface, *shellac* is obtained; it comes in thin, glossy, and more or less transparent fragments. Sometimes *grape-lac* and *lump-lac* have been distinguished, the former of which consists of agglutinated incrustations separated from the twigs; the latter is identical with shellac, except that it has not been congealed in thin layers. When chewed, stick-lac softens, and colors the saliva purplish-red, a slight bitterish and astringent taste being perceived; when burned, it gives off a strong and agreeable odor. The water in which red stick-lac has been boiled, on being treated with alum, yields *lac-dye.*

Shellac is soluble in potassa, soda, borax, muriatic and acetic acids, and when digested with ammonia in close vessels, swells to a gelatinous mass. By treating the alkaline solution with chlorine or sulphurous acid, bleached shellac is obtained.

In the year 1876–1877, the importation of stick and seed-lac amounted to 47,000 pounds, and of lac-dye to 454,781 pounds. In 1867 over 784,000 pounds of shellac were imported.

Constituents.—Lac is a complex body, containing, according to Unverdorben, five distinct resins, besides wax, fat, coloring and extractive matter. The resins may be separated by their different behavior to alcohol, ether, and alkalies.

Uses.—Shellac is used in the preparation of *varnish* and of *sealing wax,* the latter by fusing from 5 to 8 parts of it with 1 part of turpentine, and coloring the mixture with a suitable pigment. An *ink,* useful for laboratory purposes, is obtained by mixing lampblack with a solution of 100 grains of shellac and 20 grains of borax in four ounces of water.

Medical Action and Uses.—Having in a slight degree some of the qualities of the resins, lac has been used in combination with astringents as an application to indolent *ulcers,* especially of a scrofulous and scorbutic sort. It is rarely employed in medicine.

LACMUS.—LITMUS.

Lacca cœrulea, Lacca musica.—Tournesol, Laque bleu, Fr.; *Lackmus*, G.

A blue pigment obtained from Lecanora tartarea, *Acharius*, Roccella tinctoria, *Ach.*, R. fuciformis, *Ach.*, and from other lichens.

Preparation.—The lichens are powdered, mixed with some potash and urine, or other ammoniacal liquid, and exposed to the air. The liquid acquires a red, purple, and finally blue color, and is mixed with sufficient chalk to be formed into small rectangular cakes. It is manufactured in Holland.

Description.—Litmus is in earthy friable cakes, of a deep blue or purplish-blue color, and a slight saline and somewhat pungent taste. It effervesces with acids, and is partly soluble in water with a blue, and in dilute alcohol with a purplish-blue color, which is changed to red by acids.

Constituents.—Besides the earthy matter, Kane (1841) separated from litmus four coloring matters, namely: *erythrolein*, a purplish-red fatty matter, soluble in ether, fusible at 38° C. (100° F.), and yielding with ammonia a purple-colored solution; *erythrolitmin*, red, crystalline, insoluble in ether, soluble in alcohol, and changed to blue by alkalies; *azolitmin*, brown-red, amorphous, turned blue by ammonia; and *spaniolitmin*, present in minute quantity only, light red, soluble in water.

Pharmaceutical Uses.—Litmus is employed as a reagent for acids and alkalies. Litmus paper is made by making a strong aqueous solution of the coloring matter (*tincture of litmus*), and dipping white unsized paper into it. To make *red litmus paper*, dilute muriatic acid is carefully added to the blue solution until the color has just changed to red, carefully avoiding excess of the acid. When litmus is used for testing by gaslight, the change of color is best observed through a green glass.

Allied Pigments.—Archil or Orchil, *E.*, Orseille, *Fr. G.*, is made from the same lichens which yield litmus. The lichens are heated for a week with diluted ammonia, when sulphuric acid and table salt are added. Archil is a pasty mass, of a deep purple color.

Cudbear, *E.*, Orseille de terre, *Fr.*, Persio, *G.*, is made in precisely the same manner, except that, instead of adding acid and salt, the mixture is dried and powdered.

The lichens which are used for the production of the above pigments contain a number of chromogenes, which are ternary compounds, and, in the presence of water and ammonia, are converted into various nitrogenated red pigments. The most important of these chromogenes, as far as they have been investigated, are *erythric acid*, $C_{20}H_{22}O_{20}$, *alphaorsellic acid*, $C_{32}H_{28}O_{14}$, *betaorsellic acid*, $C_{34}H_{32}O_{15}$, and *evernic acid*, $C_{34}H_{32}O_{14}$. On being boiled for a long time with water or baryta, they yield *lecanoric acid*, $C_{16}H_{14}O_7$, afterwards *orsellic acid*, $C_8H_8O_4$, and finally *orcin*, $C_7H_8O_2$, which crystallizes in large colorless needles, has a sweet taste, turns red in contact with air, and yields with ammonia, *orcein*, $C_7H_7NO_3$; this is brown, and dissolves in alkalies with a beautiful red color. Orcin is also obtained from aloes by fusing it with caustic potassa.

Medical Uses.—The only use of litmus in medicine is to determine the acidity or alkalinity of the animal fluids. Litmus paper is a necessary adjunct of all apparatus for examining the urine.

LACTUCA, *Br.*—LETTUCE.

Herba lactucæ, P. G.; *Herba latucæ virosæ.—Laitue vireuse*, Fr.; *Giftlattich*, G.

The flowering herb of Lactuca virosa, *Lin.* Woodville, Med. Bot. t. 31; Bentley and Trimen, Med. Plants, 160.

Nat. Ord.—Compositæ, Liguliforæ.

Description.—This biennial herb, which grows to the height of 3 to 6 feet, has a cylindrical, somewhat prickly, pale green and often purplish-spotted stem. The large radical leaves are petiolate, obovate-oblong, obtuse, irregularly spinously toothed, wavy or nearly entire at the margin, pale green beneath, and prickly on the midrib. The stem leaves are smaller, alternate, horizontal, sessile, with a sagittate amplexicaul base, and an acute spinous apex, otherwise resembling the radical leaves, the floral ones reduced to small pointed bracts. The flower-heads form a loose terminal panicle, and are on short axillary peduncles; the involucre is oblong or conical, and composed of imbricated lanceolate bracts in about three rows; the florets are neutral, pale yellow, ligulate; the akenes are oval, flattened, black, and prolonged into a long whitish beak, bearing at its apex a pappus, consisting of numerous soft white capillary bristles. The plant has a disagreeable rather narcotic odor, and a bitter and saline taste.

It is indigenous to Western and Southern Europe, is less frequent in Central Europe, and has been naturalized in some parts of New England. It is closely allied to *L. scariola*, Lin., which is indigenous to Europe, but is found more frequently in the central part, and is distinguished from the preceding mainly by its spinescent deeply cut toothed or pinnatifid vertical leaves, but possesses the same disagreeable odor and taste, though in a rather milder degree.

Constituents.—The older analyses by Pfaff, Dublanc, and others have demonstrated the presence of principles common in herbs; among the inorganic constituents, potassium nitrate was found by Pfaff and Bley. More recently, the investigations have been confined to lactucarium, which is partly obtained from this plant.

Off. Prep.—Extractum lactucæ, *Br.*

Medical Action and Uses.—The ancients ascribed to strong-scented lettuce soporific and anaphrodisiac properties, and it was even used by them for adulterating opium. It was held to be peculiarly adapted to allay wakefulness produced by over-stimulation of the mind. Whatever may have been the virtues of lettuce in ancient Greece, they are certainly very faintly represented by the plant grown in this country and in Western Europe. They are contained in their most concentrated and available form in lactucarium. That preparation is officinal, and to the article treating of it the reader is referred for further information.

LACTUCARIUM, *U. S.*—LACTUCARIUM.

Lactucarium, Fr., G.; *Giftlattichsaft*, G.

The concrete milk-juice obtained from Lactuca sativa, *Lin.* (L. virosa, *Lin.*, *P. G.*), obtained by incision and spontaneous evaporation.

Origin and Collection.—*Lactuca virosa* and *L. scariola*, Lin., have been described above. *L. sativa*, Lin., is the common garden lettuce. *L. altissima*, Bieb., a tall Caucasian herb, is cultivated in Auvergne in France for lactucarium; Planchon regards it as a variety of *L. scariola*, Lin. We prepared (1867) very efficient lactucarium from several varieties of *L. canadensis*, Lin.

of this country, but found the milky juice, which yielded from 22 to 32 per cent. of air-dry residue, to congeal rapidly and to dry into irregular tears. Commerce is supplied with lactucarium almost exclusively from Germany and Great Britain, from plants cultivated for the purpose. Thos. Fairgrieve, who described the preparation in 1873, states that he cultivates *L. virosa* var. *montana*. The collection of the milky juice is commenced about the middle of July or beginning of August, when the flowers are just appearing, and continued for six or eight weeks until the latter part of September. The collectors proceed over the field, cutting the head of each stalk and scraping the juice into their vessels, one person who cuts being followed by two who collect the juice. This process is repeated six or seven times a day, a new cut being made each time a little lower down the stalk. In the evening, when the juice has thickened into a viscous mass, it is turned out of the vessels, suitably divided, and dried by the aid of heat, about five days being required for it.

In Germany, near the town of Zell on the Mosel, the collection lasts from May to September; the milky juice is taken up by the finger and transferred to hemispherical earthen cups, in which it quickly hardens, so that it can be turned out. It is then dried in the sunshine until it can be cut into four pieces, when the drying is completed by exposure to the air for some weeks on frames. (*Pharmacographia.*)

The lactucarium prepared in France by Aubergier is rarely if ever met with in this country. Fairgrieve obtained 1 lb. of lactucarium from 4 lbs. of juice, and estimates the average yield of each plant to be between 40 and 50 grains. By frequently puncturing the stems, Schütz (1823) obtained from *L. sativa*, *scariola*, and *virosa*, respectively, 17, 25, and 56 grains of lactucarium.

Description.—German lactucarium generally comes in sections of plano-convex circular cakes which are of a gray-brown color externally, usually white or yellowish and of a waxy lustre internally. English or Scotch lactucarium is met with in irregular sized angular pieces of a brown color and earthy appearance. Both kinds have a strongly bitter taste, and a strong narcotic odor suggesting that of opium.

What is usually sold here as French lactucarium is *extractum lactucæ*. (See page 576.)

Constituents.—Nearly one-half the weight of lactucarium is soluble in alcohol, but dilute alcohol dissolves only between 36 and 44 per cent. 50 to 60 per cent. of lactucarium consists of *lactucerin* or *lactucon*, $C_{16}H_{26}O$, which was obtained crystallized by Lenoir (1847) by exhausting lactucarium with boiling alcohol and recrystallizing the product; it forms thin colorless needles, which are inodorous and tasteless, insoluble in water, soluble in alcohol, and more freely so in ether, fixed and volatile oils. The bitter taste of lactucarium is due to three principles, two of which are uncrystallizable and freely soluble in water, while the crystallizable *lactucin*, $C_{11}H_{12}O_3.H_2O$, requires over 60 parts of cold water for solution, but dissolves more readily in hot water and in alcohol. Kromayer (1861) obtained only 0.3 per cent., which does not, perhaps, represent the whole amount present, but the much larger yields (18 to 28 per cent.) previously observed by Buchner and Ludwig must be due to impurities. Lactucin forms pearly scales, or rhombic plates, when crystallized from very dilute alcohol, has a neutral reaction, turns red and brown with alkalies, and is deprived of bitter taste; it is not a glucoside, but reduces from alkaline cupric solutions cuprous oxide. *Lactucic acid* and *lactucopicrin* have been found in the mother-liquor of lactucin; the former is light-yellow, amorphous, crystallizes on long standing, and reduces alkaline copper solutions. Lactucopicrin is brown, amorphous, insoluble in ether, soluble in alcohol, not precipitated by subacetate of lead, and appears to be produced by oxidation of lactucin.

The other constituents of lactucarium, which have been observed by different investigators, are a trace of volatile oil, asparagin, mannit, sugar, albumen, gum, resin, oxalic, citric, and malic acids, and between 8 and 10 per cent. of ash.

Off. Prep.—Syrupus lactucarii, *U. S.*

Medical Action and Uses.—With one accord the ancients attributed to lettuce soporific and anaphrodisiac qualities; but all the researches and observations made to discover its medicinal action in recent times agree in showing that its hypnotic and anodyne virtues are too slight to entitle it to much regard. That they exist, however, in a feeble degree is proved by the familiar fact that even garden lettuce used as a salad tends to produce drowsiness. It is probable that the lettuce of Greece was a much more active plant than our own. The utility of retaining lactucarium as an officinal medicine is very doubtful. It may possibly be desirable as a hypnotic for very impressionable persons with whom faith in a remedy supplies its want of intrinsic efficiency. If it have any virtues of the sort ascribed to it, they would peculiarly adapt it to cases of infantile disease. The *dose* of lactucarium is indefinite. Two grains may be given to an infant.

LAPPA, *U. S.*—BURDOCK.

Radix bardanæ, P. G.—*Bardane*, Fr.; *Klettenwurzel*, G.

The root of Lappa officinalis, *Allioni* (Arctium lappa, *Lin.*, A. majus, tomentosum, and minus, *Schkuhr.*).

Nat. Ord.—Compositæ, Cynareæ.

Origin.—We follow Gray in uniting the three forms which are often regarded as distinct, and described as *Lappa major*, Gaert., *L. tomentosa*, Lam., and *L. minor*, D. C. They are found in waste places and along roadsides in Northern Asia and throughout Europe, and have been naturalized in North America, where the variety *major* is more frequently met with than the others. They are coarse-looking biennial weeds, with branching stems 2 to 4 or 6 feet high, and cordate-oblong, nearly entire or toothed, rough, petiolate leaves. The globose involucre has the numerous scales appressed at the base, and contracted to a recurved sharp point above. The numerous tubular florets are purplish, or, rarely, whitish; the akenes are flattened and have a pappus of numerous short bristles. The variety *major* has rather large heads with a smoothish involucre; var. *tomentosa* has the involucre and peduncles woolly; var. *minor* has the heads much smaller, the involucre at first cottony, finally smooth, and the leaves usually unequally rounded or tapering at base. They bloom from July to September. The root should be collected in the autumn of the first year's growth, or early in the succeeding spring.

Description.—The root is nearly simple, 10 to 18 inches long, about 1 inch thick, gradually tapering, fleshy, and, when dry, longitudinally wrinkled, rounded at the top, and often with a tuft of white, soft, hairy leaf-stalks. It has a grayish-brown color externally, pale-brownish internally, the cross-section displaying a thickish bark, which in the inner layer is radially striate, and by a dark cambium line separated from the meditullium; this is about four times thicker, has finely porous ligneous rays, and the medullary rays of about the same width. The latter, as well as the parenchyma of the bark, are frequently partly destroyed, leaving merely the white dead tissue, which is spongy and full of holes. Burdock has a rather disagreeable, but weak, odor, and a mucilaginous, afterwards sweetish and bitterish, taste.

Constituents.—Burdock root is free from starch, but contains in its stead *inulin*. (See Inula, p. 760.) Mucilage, sugar, a bitter principle, a little resin, and some tannin have been observed in it.

Medical Action and Uses.—Burdock has had the reputation in Europe and in this country of being a depurative, as well through diaphoretic and diuretic virtues as by a more gradual and insensible modification of nutrition. It has been in vogue for the cure of *rheumatism*, *gout*, chronic *cutaneous diseases*, and chronic *pulmonary catarrhs;* it has been reputed to be diuretic (especially its seeds), and to promote the discharge of *urinary deposits;* to be alterative, also, and beneficial in constitutional *syphilis* and *scrofula*. These virtues, if they are real, would indicate that the medicine operates by promoting all the secretions, much as sarsaparilla is supposed to do. But, like that medicine, burdock is seldom given unless associated with more active agents. Externally, the expressed juice of the leaves, the fresh leaves bruised, and liniments made by boiling the leaves or the roots with oil, have been much used as popular remedies for *burns*, *wounds*, *ulcers*, and *eruptions*. Although an agent of secondary value, it is not quite just, as has been done, to call it "one of the illusions of the materia medica." Burdock is generally given in a decoction prepared by boiling two ounces of the recent bruised root in three pints of water to two pints. At least a pint a day of this decoction should be taken. Possibly the concentrated syrup or fluid extract, equally diluted, would answer equally well.

LARICIS CORTEX, *Br. Add.*—LARCH BARK.

Écorce de mélèze, Fr.; *Lärchenrinde*, G.

The bark, deprived of its outer layer, of Larix Europæa, *D. C.* (Abies Larix, *Rich.;* Pinus Larix, *Lin.*)

Nat. Ord.—Coniferæ, Abietineæ.

Origin.—The European larch is a forest tree of Southern and Central Europe, where it grows chiefly in mountainous localities up to an altitude of about 5000 feet. It is often cultivated in Europe, and has been introduced in North America as an ornamental tree. It attains a height of 80 to 100 feet, has the narrow linear deciduous leaves in fascicles of 20 to 40, and oblong ovoid erect cones, which are about 1 inch long. The bark is collected from the trunk and the branches.

Description.—The bark has a brown-gray or when older a reddish-brown fissured corky layer, which is to be removed. The liber has a reddish or pinkish hue, the inner surface is smooth, of a yellowish or pale brown color. It breaks with a short somewhat fibrous fracture, displaying rather indistinct medullary rays and some resin ducts. Larch bark has an agreeable terebinthinate odor, and a balsamic and astringent taste.

Constituents.—Stenhouse (1861) found larch bark to contain a good deal of peculiar *tannin*, which yields olive-green precipitates with salts of iron, turns red on being boiled with dilute sulphuric acid, but does not yield any *sugar*, which however is contained in the decoction of the bark, together with a considerable quantity of *mucilage* and *resinous matter*. He obtained also a volatile acid, by evaporating the warm infusion of the bark to a syrupy consistence, and then distilling it. The *larixinic acid*, $C_{10}H_{10}O_5$, crystallizes partly in the neck of the retort, the remainder is obtained by carefully concentrating the distillate and purifying the product by sublimation. The bark of the branches and of trees not over thirty years old yields the largest proportion. It forms long colorless crystals resembling those of benzoic acid, sublimes at 93° C. (199.4° F.), fuses at 150° C. (302° F.), has a bitterish and astringent taste, and a camphoraceous odor. Its combinations with alkalies are red-brown, and decomposed by carbonic acid; baryta solution causes a bulky precipitate; ferric salts produce a purple color, and on boiling it with silver salts, the metal is separated; nitric acid oxidizes it to oxalic acid. It is sparingly soluble in ether, and freely soluble in alcohol and hot water. It is allied to pyrogallic acid and pyrocatechin.

Other products of the larch are Venice turpentine and Briançon manna.

The bark of the American larch, *Larix Americana*, Mich., which is more slender, and has shorter leaves and smaller cones, deserves to be investigated.

Off. Prep.—Tinctura laricis, *Br.*

Medical Action and Uses.—Its action does not differ from that of other terebinthinate and balsamic remedies, but it has a less disagreeable flavor. With the inner bark a saturated tincture has been prepared, and highly recommended in *chronic bronchitis* and in chronic inflammation of the *urinary* mucous membrane. It has also been used in *purpura hemorrhagica.* The *dose* of the tincture is from twenty to thirty minims.

LAUROCERASI FOLIA, *Br.*—CHERRY LAUREL LEAVES.

Folia laurocerasi, P. G.—*Feuilles de laurier-cerise*, Fr.; *Kirschlorbeerblätter*, G.

The fresh leaves of Prunus laurocerasus, *Lin.* (Cerasus lauro-cerasus, *Loisel.*). Steph. and Church, Med. Bot., plate 117; Bentley and Trimen, Med. Plants, 98.

Nat. Ord.—Rosaceæ, Amygdaleæ.

Origin.—The cherry laurel is a small evergreen tree, or is frequently a shrub 15 to 20 feet high, with a smooth brownish bark and pale green branches, and produces pendulous racemes of dark purple shining cherry-like drupes. It is a native of Western Asia from Northern Persia to Asia Minor, but it has been naturalized in Southern Europe, and is cultivated in the open air as an ornamental shrub northward to Southern Germany and England.

Description.—The leaves are leathery, glossy and dark green above, pale green beneath, oblong in outline, narrowed above to an obtuse point, and below to a short petiole. They are about 4 to 6 inches long, and 1½ to 2½ inches wide, somewhat revolute on the margin, with distant and small but sharp serratures. The midrib is quite prominent on the lower surface, and has near its base one or two pairs of depressed glands. The unbroken fresh leaves are inodorous, but when broken they have a strong bitter almond odor; their taste is aromatic, bitter, and somewhat astringent.

Constituents.—Cherry laurel leaves contain some sugar, tannin, wax, fat, and, according to Stange (1823), an acid allied to if not identical with malic acid. The same author recognized also the production of *benzoic acid* from the volatile oil in the presence of oxygen. Liebig and Wöhler did not succeed in isolating amygdalin, from which they supposed the volatile oil to be derived. F. L. Winckler (1839) obtained the bitter principle as a soft transparent wine-yellow mass, which, when treated with dilute sulphuric acid and manganic binoxide, yielded a distillate of a very agreeable odor, which did not contain hydrocyanic acid. When treated with emulsion of sweet almonds, the taste became gradually less bitter, and the odor of bitter almonds became afterwards apparent. It seems therefore as if the leaves contained a compound from which amygdalin must be first produced before the volatile oil can be obtained, which has the same composition as oil of bitter almonds. Broeker (1867) observed that the watery distillate is strongest in hydrocyanic acid if the leaves were collected in the summer. Schoonbroodt (1869) obtained from the aqueous extract, on treatment with ether, some bitter crystals, which reduced cupric oxide.

Off. Prep.—Aqua laurocerasi, *Br.*

Medical Action and Uses.—Cherry laurel leaves are officinal in the British Pharmacopœia chiefly as the source from which cherry laurel water is obtained. Their medical virtues depend upon the hydrocyanic acid which they furnish. Its action and uses are treated of under Aqua laurocerasi and Acidum hydrocyanicum. The bruised fresh leaves are used as anodyne applications to painful parts.

LAURUS.—Laurel.

Bay, Sweet bay, E.; *Laurier commun*, Fr.; *Lorbeer*, G.

Laurus nobilis, *Lin.* *Nat. Ord.*—Lauraceæ.

Origin.—The bay tree is indigenous to the Levant, and grows wild in the countries bordering the Mediterranean. It is a small tree or large shrub with umbellate clusters of yellowish flowers. The leaves and fruit have been used.

Description. 1. The Leaves.—They are 3 or 4 inches long, an inch or more broad, shortly petiolate, coriaceous, smooth, pellucid-punctate, oblong or oblong-lanceolate, acute at both ends, entire, glossy above, veined beneath, and when dry of a yellowish- or brownish-green color. They have a pleasant aromatic odor, and an aromatic and bitterish taste.

2. The Fruit.—The so-called *bay-berries* are oval drupes about one-third of an inch long. When dry they are greenish-black or blackish-brown, slightly wrinkled, and fragile, the integuments, including the reddish-brown endocarp, being thin and brittle. The loose oval seed is easily separated into the two plano-convex brownish cotyledons, which have an aromatic oily and bitter taste. By expression of the bruised fruit, after steeping it in hot water, oil of bays, *Oleum lauri* (*s. laurinum*), P. G., is obtained. It has the consistence of lard, a granular appearance, a green color, and an aromatic odor and taste. It is soluble in ether, partly soluble in alcohol, and does not yield its coloring matter to water.

Constituents.—The leaves and fruit contain a volatile oil. The volatile oil of bay-berries is pale yellow, of the spec. grav. 0.91, congeals at a low temperature, contains oxygen, and is easily soluble in alcohol; it contains a more volatile elæopten and a solid stearopten. The seeds contain, according to Bonastre (1824) about 20 per cent. of fat, 2 per cent. of volatile oil, and 1.5 per cent. of resin. The solid fat of oil of bays is principally *lauro-stearin*, the glyceryl compound of *lauric acid* $C_{12}H_{24}O_2$.

Medical Action and Uses.—Bay leaves and berries were anciently held in high esteem as stimulant, stomachic, and astringent, and in substance or decoction were much used for the stings of insects, eruptions of the scalp, and vaginal relaxation with leucorrhœa; a decoction of the root bark was given internally in diseases of the urinary organs and in dropsy, and was regarded as a powerful emmenagogue. More efficient medicines have supplanted it, and it is now seldom used except in the form of its volatile and fixed oils for relieving local rheumatic and other pains. In Europe the fresh leaves continue to be employed for flavoring pastry and rendering it more digestible.

LAVANDULA, *U. S.*

Flores lavandulæ, P. G.; *Flores lavendulæ.*—*Lavender, Lavender flowers*, E.; *Fleurs de lavande*, Fr.; *Lavendelblüthen*, G.

The flowers of Lavandula vera, *D. C.* (L. spica, var. α, *Lin.*; L. angustifolia, *Ehrh.*; L. officinalis, *Chaix*). Bentley and Trimen, Med. Plants, 199.

Nat. Ord.—Labiatæ, Nepeteæ.

Origin.—Lavender is a native of Southern Europe, from Italy to Spain and to Northwestern Africa, growing upon sunny hillsides and mountains. It is extensively cultivated as an ornamental garden plant, and in Europe also for the purpose of distilling the volatile oil. (For an account of the cultivation of lavender at Hitchin, England, see *Proc. Amer. Pharm. Assoc.*, 1876, p. 819–821.) The plant is shrubby, about two feet high, has a brown-gray bark, which is much cleft when old; opposite, sessile, entire, and linear leaves, with revolute margins and long stalked terminal spikes, on which the lower whorl of flowers is remote from the others. The flowers are collected in June and July, before fully expanded, and require to be carefully dried.

Description.—The calyx is tubular, contracted and naked at the mouth, with the upper tooth roundish, rhomboid, and the remaining four teeth obsolete, densely covered with short hairs and minute glands, and of a blue-gray color. The corolla exceeds the calyx, and is violet-blue, tubular, enlarged above, hairy and glandular on the outside, and two-lipped, the upper lip being erect and two-lobed, and the lower lip spreading and three-lobed. The four stamens are quite short, and inserted in the middle of the hairy corolla tube. Lavender flowers have an agreeable aroma, which becomes more apparent on bruising and rubbing them, and a bitterish aromatic, somewhat camphoraceous taste.

Constituents.—Besides some tannin, resin, and other widely diffused principles, lavender flowers contain volatile oil, when fresh yielding about 1 per cent. (See Oleum lavandulæ.)

Medical Action and Uses.—Lavender is a stimulant aromatic, remarkable for its refreshing perfume. It is seldom used internally, unless in the form of oil or spirit, and then associated with other medicines. The infusion is said, when too freely taken, to occasion colic. Fomentations made with lavender inclosed in bags allay local pains, like other plants of the labiate family.

LEDUM.—MARSH TEA.

Marsh cistus, *Wild rosemary*, E.; *Lédon*, *Romarin sauvage*, Fr.; *Sumpfporst*, *Wilder Rosmarin*, G.

The leaves of Ledum palustre, *Lin.* *Nat. Ord.*—Ericaceæ, Ericineæ.

Origin.—This shrub grows in marshy locations in the northern sections of North America, Asia, and Europe. It is about three feet high, and has white or pale rose-red five-petaled flowers in umbellate clusters.

Description.—The leaves are coriaceous, about an inch long, linear or lance-linear, obtuse, with a revolute margin, dark-green, smooth and with depressed veins above, and clothed with a rusty wool on the lower side. They have a peculiar heavy aromatic odor, and a bitter aromatic somewhat camphoraceous taste.

Constituents.—Meissner's results (1827) with marsh tea were further investigated by Willigk (1852) and others. The tannin, *leditannic acid* $C_{14}H_{12}O_6$, was obtained as a reddish powder, which dissolves in water and alcohol, and colors ferric salts dark green. The volatile oil, about 1½ per cent., is yellow, pungently aromatic, and contains a stearopten, *ledum camphor*, probably $5C_{10}H_{16}.3H_2O$, which has been examined by Grassmann (1831) and Buchner (1856); it is in silky needles, fusible and sublimable. Frœhde (1861) recognized in the volatile oil the presence of valerianic and other volatile acids, and of *ericinol* $C_{10}H_{16}O$; this is likewise contained in other ericaceous plants, or obtainable from them as a decomposition product of the glucoside *ericolin* $C_{34}H_{56}O_{21}$, which has been discovered by Rochleder and Schwarz (1852), and is brown-yellow, bitter, soluble in water, alcohol, and alcoholic ether, and not precipitated by lead salts. The remaining constituents of marsh tea are citric acid, resin, wax, and other ordinary vegetable principles.

Allied Plants.—LEDUM LATIFOLIUM, *Ait.*, known as *Labrador tea* and *James tea*, is indigenous to the Northern United States and to British America. The leaves resemble the preceding, but are broader, elliptic-oblong, and occasionally slightly heart-shaped at the base. They probably contain the same constituents.

ANDROMEDA POLIFOLIA, *Lin.*, indigenous to marshes of Northern Asia, Europe, and America, is also known as *wild rosemary*. The leaves are about an inch long, linear-lanceolate, acute, strongly revolute at the margin, greenish-white beneath, otherwise resembling the preceding. They are considered to possess acrid and somewhat narcotic properties.

Medical Action and Uses.—This plant has been ranked with acrid-narcotic medicines, and is stated, in large doses, to occasion headache, restlessness, sleeplessness, dyspnœa, cough, dilatation of the pupils, a sort of intoxication, with pain in the limbs, increased secretion of urine, saliva, and especially of sweat, with itching and an eruption of papules or pustules on the skin. It is said to have been used in the manufacture of beer to render it more intoxicating. It was formerly employed in diarrhœa, dysentery, whooping-cough, croup, gouty and rheumatic pains, and all sorts of chronic cutaneous eruptions. Its use for such purposes is, however, obsolete. A strong decoction of the plant is used to destroy cutaneous parasites in horses and neat cattle, and to cleanse bedsteads of vermin; and the leaves and twigs of the fresh plants are laid among woollen clothing to protect it against moths.

LEONURUS.—MOTHERWORT.

Agripaume, Cardiaire, Fr.; *Herzgespann, Wolfstrapp,* G.

Leonurus cardiaca, *Lin.* *Nat. Ord.*—Labiatæ, Stachydeæ.

Description.—Motherwort is a perennial herb growing in waste places and near dwellings throughout Europe, Northern Asia, and North America. It is 3 or 4 feet high, and has a quadrangular rather rough stem. The lower leaves are roundish, often heart-shaped at the base, and palmately five to seven-lobed; the upper ones are oblong, acutely three-lobed, and have a wedge-shaped base. The pale purplish flowers have awl-shaped or spiny-toothed calyx teeth, and are in dense axillary cymules. The plant has a rather unpleasant aromatic odor, and a bitter taste.

Constituents.—It evidently contains volatile oil; the bitter principle has not been isolated.

Allied Plants.—Of the numerous plants belonging to the tribe Stachydeæ the following seem to deserve a brief notice (see also Marrubium and Scutellaria):—

STACHYS PALUSTRIS, *Lin.*, Hedge nettle, *E.*, Ortie rouge, *Fr.*, Stinknessel, Sumpfziest, *G.*, grows in wet places in Europe and North America. The stem is stiff-hairy. The leaves are mostly sessile, about 3 inches long, varying between ovate and linear-lanceolate, round or heart-shaped at the base, rather obtuse, hairy, and on the margin crenately serrate. The flowers are in whorls of 6 to 10, have sharply subulate calyx teeth, and a purple somewhat spotted corolla.

GALEOPSIS TETRAHIT, *Lin.* Hemp nettle, *E.*; Chanvre bâtard, Galeopside, *Fr.*; Hanfnessel, Hohlzahn, *G.*—Introduced from Europe into North America. The stem is densely bristly-hairy below the joints; the leaves are about 2 inches long, ovate, usually acute, rather rounded at the base, coarsely serrate. The flowers are in dense axillary clusters, have long spiny-toothed calyx teeth, and a white or yellowish corolla, with a purple spot on the lower lip.

The allied species, Gal. ochroleuca, *Lam.*, and G. grandiflora, *Roth*, at one time attracted attention in Europe as the principal ingredients of a nostrum sold as *Blankenheim tea* or *Lieber's consumption herbs.*

BALLOTA NIGRA, *Lin.* Black horehound, *E.*; Marrube noir (fétide), *Fr.*; Schwarzer Andorn, *G.*—Sparingly naturalized in New England. The stem is hairy, often red-brown; the leaves are about 1½ inch long, wrinkled, hairy, ovate, slightly heart-shaped, acute, and crenately toothed. The reddish-purple flowers are in axillary clusters of 5 to 9.

LAMIUM ALBUM, *Lin.* Dead nettle, *E.*; Ortie morte, *Fr.*; Taubnessel, *G.*—It has likewise been introduced from Europe, has ovate, heart-shaped, pointed and coarsely serrate, somewhat hairy, petiolate leaves, and white or whitish flowers in dense axillary clusters, and slender calyx teeth. Lamium amplexicaule, *Lin.*, and L. purpureum, *Lin.*, are more frequent in the United States; they have roundish leaves and smaller purplish flowers.

Many other species of the above genera have been employed in Europe and Asia, and like the above contain volatile oil and a bitter principle.

Medical Action and Uses.—A decoction of motherwort is sometimes used in Europe to promote digestion and quicken the functions of the skin. In the same countries L. lanatus is regarded as a vascular stimulant and diuretic, and also as a general tonic; it is employed in dropsy, especially of hepatic origin, and is stated to impart to the urine a dark-brown color; it is also used in chronic gout and rheumatism, and to relieve uterine obstructions.

LEPTANDRA, *U. S.*

Leptandra, Culver's root, Culver's physic, Black root, E.; *Racine de leptandra, s. de véronique de Virginie,* Fr.; *Leptandra-Wurzel,* G.

The rhizome with the rootlets of Leptandra virginica, *Nuttall* (Veronica virginica, *Lin.*). Bentley and Trimen, Med. Plants, 196.

Nat. Ord.—Scrophulariaceæ.

Origin.—Leptandra is indigenous to Canada and the United States as far west as the Mississippi Valley; in its southern locations it grows in mountain valleys, and further north in low grounds and rich woodlands. It sends up an obtusely angular stem, 3 to 6 feet high, has the short-petioled, lanceolate and serrate leaves in verticils of 4 or 5, and the white flowers with the two much exserted stamens in panicled spikes, 3 to 6 inches long. It flowers in July and August, and produces ovate, two-celled, and many-seeded capsules.

Description.—The rhizome is 4 to 6 inches long, and about $\frac{1}{4}$ inch thick, horizontal, somewhat bent and branched, blackish-brown to brown-black, nearly free from wrinkles, but the bark is sometimes transversely fissured. The upper side has short remnants of the stems or cup-shaped scars, $\frac{3}{4}$ to 2 inches apart; the numerous rootlets, which are chiefly attached to the lower side, are blackish, about $\frac{1}{16}$ inch thick, longitudinally wrinkled, quite fragile, and therefore usually detached and much broken. The rhizome is hard, and breaks with a woody fracture, showing a large purplish-brown pith, and few medullary rays dissecting the yellowish wood, which is 8 to 10 times thicker than the blackish-gray bark. The ligneous cord of the rootlets is of about the same thickness as the bark. Leptandra has no odor; its taste is bitter and feebly acrid.

Constituents.—According to the analysis of Prof. Wayne (1856), leptandra contains, besides widely diffused principles, like tannin, gum, resin, and a trace of volatile oil, a principle having the nauseous bitter taste of the drug, and therefore deserves to be called *leptandrin*. It is soluble in water, alcohol, and ether, and was obtained by precipitating the infusion with subacetate of lead, removing the excess of lead from the filtrate by sodium carbonate, and passing the liquid through a column of animal charcoal; this was washed with water and then treated with boiling alcohol, and the extract left on evaporation treated with ether; on evaporating the ether spontaneously, a portion of leptandrin crystallized; the remainder was contaminated with coloring matter, which prevented it from crystallizing. The so-called *leptandrin* of the eclectics, which is obtained by precipitating the concentrated tincture with water, appears to owe its efficacy to the accidental presence of the principle described. From the mother liquor of this eclectic preparation, Wayne (1859) obtained *mannit.* F. F. Mayer (1863) observed the bitter principle to be at least partly precipitated by tannin, and that portion to be a glucoside; he also found *saponin*, some *citric acid*, and a small quantity of a *volatile alkaloid*.

A fluid extract of leptandra is sometimes employed; it is prepared by exhausting the drug with alcohol.

Medical Action and Uses.—Although this medicine has long been in use, and is officinal, we do not learn that it has commended itself to educated physicians by its peculiar virtues, although they are sufficiently marked to merit greater attention. The root, when fresh or recent, acts violently as an emeto-cathartic, and the impure resin obtained from it, and ignorantly called leptandrin, as if it were itself the proximate active principle of the plant, produces similar effects, when the dose is excessive. Like all gastro-intestinal irritants, it probably promotes the secretions of the mucous glands, the pancreas, and the liver, but has no specific influence upon the last-named organ, as has been confidently assumed. The *dose* of the powder is stated to be from twenty to sixty grains, and of leptandrin from two to four grains. It has also been given in tincture and fluid extract.

LEVISTICUM.—LOVAGE.

Radix levistici, P. G.—*Livèche, Ache de montagne*, Fr.; *Liebstöckel*, G.

The root of Levisticum officinale, *Koch*, s. Ligusticum levisticum, *Lin.*

Nat. Ord.—Umbelliferæ, Orthospermæ.

Origin.—Lovage is indigenous to the mountainous districts of Southern Europe, has a stem about 5 feet high, terminal umbels of yellow flowers, and elliptical or oval fruits with winged ribs, and one or more oil-tubes in each groove. The plant is sometimes cultivated in gardens.

Description.—The root is about 6 inches long, 1 or 1½ inch thick, several-headed, indistinctly annulate, longitudinally wrinkled, somewhat branched below, yellowish-brown externally, and pale-yellowish internally. It has a thick bark, which is radially striate from the medullary rays, fissured in the outer portion, and contains numerous orange-yellow resin-cells, arranged in irregular concentric circles. The meditullium is denser, but soft, has narrow medullary rays, and in the upper portion a central pith. It has a strong balsamic odor, somewhat resembling that of angelica, and a mucilaginous, aromatic, and pungent taste.

The root of Ligusticum actæifolium, *Mich.*, which is indigenous to the Southern United States, is similar in appearance and properties.

Constituents.—Lovage was analyzed by Trommsdorff (1836), Riegel (1840), and others, and found to yield a thickish volatile oil containing much stearopten, various resins, some soft, others hard, one having a bitter and pungent taste, sugar, mucilage, and other common principles.

Allied Drugs.—PIMPINELLA SAXIFRAGA, *Lin.;* Small burnet saxifrage, *E.;* Grand boucage, *Fr.;* Pimpinell, Biebernell, *G.*—Indigenous to Europe and Asia. The root resembles the preceding, but is brown-yellow, usually one-headed. not over ½ inch thick, finely annulate above and verrucose below; the bark is very thick, spongy, contains numerous resin-cells, and is radially striate, either white or yellowish, inclosing a yellow wood. The constituents are similar to those of the preceding.

LASERPITIUM LATIFOLIUM, *Lin.*—The root was formerly known as *Radix gentianæ albæ*, from its resemblance in shape to that of gentian root, but it is externally brownish-white, internally white, and contains yellow resin-cells in the thick spongy bark.

PEUCEDANUM OFFICINALE, *Lin.*—The root is externally blackish, internally brownish-yellow, with a rather thick bark containing numerous orange-colored resin-cells in radial rows, and inclosing a soft porous wood with resin-cells in the medullary rays.

Medical Action and Uses.—Levisticum belongs to the large class of plants containing an essential oil and a resin, which have always been employed as carminatives, diuretics, emmenagogues, and digestive stimulants. It has been much used in flatulent *dyspepsia*, *amenorrhœa*, and *dropsy*, especially in Germany. It is administered in decoction or infusion, in tablespoonful doses.

LIATRIS.—Liatris.

Nat. Ord.—Compositæ, Eupatorieæ.

Description.—The genus Liatris embraces principally North American perennial herbs with tuberous roots, simple and erect stems, alternate and entire leaves, and handsome rose-purple flower-heads with an oblong imbricate involucre, naked receptacle, and a pappus composed of many bristles. The flowers are usually in terminal spikes or racemes.

Liatris spicata, *Willd.*—The tuberous rhizome is known as *Button snake-root*, *Devil's bit*, and *Colic root.* It is $\frac{1}{2}$ inch or more in diameter, somewhat tuberculate from short branches, and marked with several cup-shaped stem-scars. It is slightly wrinkled and of a brown color externally, and internally of a dingy white, with streaks of brown. Its odor is somewhat balsamic, and its taste warm and bitterish.

L. squarrosa, *Willd.*, and L. scariosa, *Willd.*, are known as *Rattlesnake's master.* The rhizomes resemble the preceding, but are more elongated, irregularly ovate, and beset with a few wiry rootlets. Internally they are of a brownish color.

L. odoratissima, *Willd.* *Vanilla plant* or *Deer's tongue.*—The radical leaves are obovate-spatulate, obtuse, about 7-veined, narrowed below; the stem-leaves are oval or oblong, and clasping at the base. All the leaves are rather fleshy, pale green, and smooth, and, after drying, have a very agreeable odor.

Constituents.—The rhizomes appear to contain volatile oil and resin. The leaves of the deer's tongue were found by Procter (1859) to contain coumarin, which is frequently separated upon the surface in crystals.

Pharmaceutical Uses.—Their agreeable and persistent odor renders deer's tongue leaves serviceable in the preparation of sachet powders, etc., as suggested by Dr. A. W. Miller (1875).

Medical Action and Uses.—L. spicata is one of the numerous "snake-roots" which owe whatever virtue they possess to being diaphoretic when administered in hot decoction, in consequence of the acrid or stimulant principle they contain. These qualities also adapt them to relieve flatulent *colic.* They are also diuretic, and are used in nephritic complaints. L. odoratissima has an odor resembling that of vanilla, for which reason it is sometimes mixed with smoking tobacco, and introduced into segars. Other species, L. scariosa and L. squarrosa, are especially high in popular esteem as antidotes to the rattlesnake's bite, and are employed in *gonorrhœa*, and also to prepare gargles for *sore throat.*

LIGUSTRUM.—Privet.

Troène, Fr.; *Rainweide*, *Hartriegel*, G.

Ligustrum vulgare, *Lin.* *Nat. Ord.*—Oleaceæ.

Description.—The privet is a shrub, 8 or 10 feet high, indigenous to Southern Europe; it is cultivated for ornament and in hedges, and is naturalized in the United States. The *leaves* are opposite, elliptic-lanceolate, smooth, thickish, entire on the margin, and about 2 inches long; they have a bitterish and astringent taste. The *flowers* are in panicles, the calyx short, the corolla funnel-shaped, 4-lobed, white, and of a sweetish agreeable odor. The *berries* are globular-oval, black externally, dark-purple internally, two-celled, and contain 2 or 4 ovate-oblong acute seeds.

Constituents.—According to Stenhouse (1854) the leaves contain a principle which yields *quinone*. The bitter principle, *ligustrin*, was not completely isolated by Polex (1839) and Kromayer (1854). It appears to be insoluble in absolute alcohol and ether, and to be allied to *syringin*, the bitter principle of *lilac*, Syringa vulgaris, *Lin.* *Ligustron* is a crystalline, bitter, and fusible principle, obtained by Kromayer.

Medical Action and Uses.—The leaves and bark are strongly astringent, and were formerly used to restrain hemorrhages, and are still employed in gargles in various forms of sore mouth and throat.

LIMONIS CORTEX, *U. S.*, *Br.*—LEMON-PEEL.

Cortex fructus citri, P. G.—*Écorce (zeste) de citron, de limon*, Fr.; *Citronenschale, Limonenschale*, G.

The rind of the fruit of Citrus limonum, *Risso* (C. medica var., *B. Lin.*). Steph. and Church, Med. Bot., plate 92; Bentley and Trimen, Med. Plants, 54.

Nat. Ord.—Aurantiaceæ.

Origin.—The lemon is a native of the northwestern part of India, where it is found in the forests up to an altitude of about 4000 feet. It is extensively cultivated in the basin of the Mediterranean, and the culture has also been introduced into the southern parts of the United States, in Australia, and most tropical and subtropical countries. Several varieties have been produced from the original stock, of which, besides the lemon, the following are quite distinct:—

C. medica, Risso, *Citron* or *Cedrat.*—Its flowers are purplish externally; the fruit is large, has a rugged and thick rind, and contains an acid juice.

C. limetta, Risso, *Lime.*—Its flowers are white; the fruit is smaller than the lemon, oval or roundish, has a smoother and thin rind, and contains a very acid juice.

The *lemon-tree* is 12 to 15 feet high, irregularly branched and spiny in the leaf-axils; the leaves are oval or ovate-oblong, somewhat serrate, leathery, glossy above and articulated with the wingless or slightly winged petiole. The flowers are mostly solitary, have a small calyx, five petals, which are purplish-pink externally, and numerous stamens. The fruit varies in shape between oval and obovate, has a nipple-shaped apex, a yellow nearly smooth pericarp, and is divided into 8 to 12 cells, each with 2 or 3 seeds.

Description.—Lemon-peel forms either narrow bands or more frequently oblong and curved sections; the outer surface has a deep lemon-yellow color, and is somewhat uneven and rough from numerous oil cells imbedded in the tissue. This portion has an agreeable odor and an aromatic slightly bitter taste; it is the only part which possesses any medicinal value. The white spongy tissue underneath, which is inodorous and nearly tasteless, should be rejected.

Constituents.—The principal constituent is volatile oil (see Oleum limonis). The bitter taste is probably due to hesperidin (see page 258). The white portion is colored black by ferric salts; the principle which gives rise to this color has not yet been isolated.

Off. Prep.—Infus. aurantii comp., Infus. gentianæ comp., *Br.;* Spiritus limonis, *U. S.;* Syrupus limonis, Tinctura limonis, *Br.*

Medical Uses.—Lemon-peel is used in medicine, as in cookery, for the sake of its flavor.

LIMONIS SUCCUS, *U. S.*, *Br.*—LEMON-JUICE.

Succus citri.—*Suc de citron* (*de limon*), Fr.; *Citronensaft*, *Limonensaft*, G.

The juice of the fruit of Citrus limonum; *D. C.*

Origin.—See the preceding article. The juice is obtained by expressing the ripe fruit.

Description.—Lemon-juice is a slightly turbid yellowish liquor, which has the agreeable odor of lemon and an acid taste. Stoddart determined its usual specific gravity to be 1.044, and each fluidounce to contain 44 grains of citric acid (42.5 grains in one imperial fluidounce); its acid strength, however, is subject to variation. Lemon-juice speedily undergoes decomposition, and various methods for its preservation have been suggested, most of which, however, fail to preserve it in condition for medicinal use. It has been proposed to concentrate it by evaporation or freezing before bottling it, or to exclude the air by a stratum of fixed oil; the flavor, however, is considerably modified. A better method is to clarify the juice by adding half its volume of strong alcohol, the decanted liquid is then freed from alcohol at a very moderate heat, and the remaining liquid put into suitable bottles, which are heated to near the boiling point for about an hour, and then hermetically sealed. The juice may be preserved by the same method; but the flavor will be impaired on keeping.

Constituents.—Lemon-juice contains about 10 per cent. of citric acid and 3 to 4 per cent. of gum and sugar. By evaporation and incineration, H. M. Witt (1854) obtained between 0.2 and 0.5 of ash, the principal constituents of which were potassa 44.34, lime 7.61, and phosphoric acid 7.56 per cent. Cossa (1872).

Off. Prep.—Mistura potassii citratis, *U. S.;* Syrupus limonis, *U. S.*, *Br.*

Medical Uses.—Lemon-juice is essentially a solution of free citric acid. (See Acidum citricum.)

LINARIA.—TOAD-FLAX.

Herba linariæ, P. G.—*Linaire commune*, Fr.; *Löwenmaul*, *Marienflachs*, G.

Linaria vulgaris, *Mill.*, s. Antirrhinum linaria, *Lin.*

Nat. Ord.—Scrophulariaceæ.

Description.—The toad-flax or *ramsted*, also called *butter-and-eggs*, is a European perennial, now extensively naturalized in North America. It is one or one and a half foot high, has alternate, sessile, lance-linear, almost three-nerved, smooth and light-green leaves, one or one and a half inch long; and terminal racemes of showy yellow flowers, which have a personate corolla about two-thirds inch long, and at the base continued into a curved spur of the same length. When fresh, the herb has a slight disagreeable odor and a bitterish taste.

Constituents.—The flowers were analyzed by Riegel (1843); they contain a yellow coloring matter, mucilage, sugar, etc.

Medical Action and Uses.—The use of common toad-flax for jaundice, dropsy, and diseases of the skin, and of an ointment made with it for the cure of hemorrhoids, is now entirely obsolete.

LINI FARINA, *U. S.*, *Br.* See LINUM.

LINIMENTA.—LINIMENTS.

Embrocations, E., Fr.; *Linimente*, *Einreibungen*, G.

Liniments are liquid or semi-liquid preparations which are intended for external use, and are applied to the skin by friction. The vehicle may be oil or alcohol, or sometimes water; many are perfect solutions, others mechanical mixtures, which should be well agitated before they are used; a few are of a soft solid consistence at the ordinary temperature, but become liquid when applied to the skin.

LINIMENTUM ACONITI, *U. S.*, *Br.*—LINIMENT OF ACONITE.

Liniment d'aconite, Fr.; *Akonitliniment*, G.

Preparation.—Take of Aconite Root in fine powder eight troyounces; Glycerin a fluidounce; Alcohol a sufficient quantity. Moisten the powder with four fluidounces of alcohol, and let it macerate for twenty-four hours; then pack it in a conical percolator, and gradually pour alcohol upon it until two pints of tincture have been obtained. Distil off a pint and a half of alcohol, and evaporate the remainder until it measures seven fluidounces; to this add the glycerin, and mix them thoroughly. *U. S.*

Take of Aconite Root in coarse powder twenty ounces; Camphor one ounce; Rectified Spirit a sufficiency. Moisten the aconite with some of the spirit, and macerate in a closed vessel for three days; then transfer to a percolator, and adding more spirit percolate slowly into a receiver containing the camphor, until the product measures one pint (imperial). *Br.*

The first formula is essentially the same as that suggested by Procter in 1853. Both preparations have the strength of fluid extracts, and differ from each other mainly in the fact that the latter contains some camphor; the root, however, is not completely exhausted by the second process.

Medical Uses.—This liniment is convenient for the local use of aconite, and for addition to other anodyne applications. It is chiefly employed for the relief of *neuralgia* by saturating with it disks or pledgets of cloth which are then applied to the painful part. Mixed with an equal quantity of soap liniment it is said to effectually remove the pain of *dry gangrene.*

LINIMENTUM AMMONIÆ, *U. S.*, *Br.*—LINIMENT OF AMMONIA.

Linimentum ammoniatum, P. G.; *Linimentum volatile*, *Linimentum ammoniacale.*—*Volatile liniment*, E.; *Liniment ammoniacal* (*volatil*), *Savon ammoniacal*, Fr.; *Flüchtiges Liniment*, *Flüchtige Salbe*, G.

Preparation.—Take of Water of Ammonia a fluidounce; Olive Oil two troyounces. Mix them. *U. S.*

Take of Solution of Ammonia one fluidounce; Olive Oil three fluidounces. Mix together with agitation. *Br.*

The German Pharmacopœia directs four parts of olive oil, and the French Codex nine parts of expressed oil of almonds to one part of ammonia water.

The fixed oil is partly decomposed, with the formation of an ammonia soap, by means of which the water and oil are kept well mixed, forming a stiff opaque emulsion, which Rother (1872) renders sufficiently fluid by the addition of one-sixteenth volume of alcohol. On being kept, the liniment becomes thicker, and finally forms a stiff and even granular mass, which Rother prevents by the addition of a minute quantity of oleic acid.

Some Pharmacopœias recognize also a *Linimentum ammoniæ camphoratum*, *camphorated volatile liniment*, which is made in precisely the same manner, except that camphor liniment is substituted for the fixed oil.

Medical Uses.—This preparation represents the stimulant rather than the counter-irritant virtues of ammonia. It is used to relieve local pains of a *neuralgic* or *rheumatic* nature, and to palliate both pain and congestion in the forming stage of various inflammations, as *sore throat*, *laryngitis*, *bronchitis*, and *pleurisy*. If prevented from evaporating, it may vesicate the skin.

LINIMENTUM BELLADONNÆ, *Br.*—LINIMENT OF BELLADONNA.

Liniment de belladonne, Fr.; *Belladonna-Liniment*, G.

Preparation.—Take of Belladonna Root in coarse powder twenty ounces; Camphor one ounce; Rectified Spirit a sufficiency. Moisten the belladonna with some of the spirit, and macerate in a closed vessel for three days; then transfer to a percolator, and adding more spirit percolate slowly into a receiver containing the camphor, until the product measures one pint (imperial). *Br.*

The formula is identical with that given for aconite liniment in the same Pharmacopœia; the root is not exhausted.

Medical Uses.—Belladonna liniment is a convenient and efficient preparation for allaying the local pains which belong to neuralgia, rheumatism, sprains, etc. It is advantageously associated with aconite liniment.

LINIMENTUM CALCIS, *U. S.*, *Br.*

Lime liniment, *Liniment of lime*, E.; *Liniment calcaire*, *Savon calcaire*, Fr.; *Kalkliniment*, G.

Preparation.—Take of Solution of Lime eight fluidounces; Flaxseed Oil seven troyounces. Mix them. *U. S.*

Take of Solution of Lime, Olive Oil, of each two fluidounces. Mix together, with agitation. *Br.*

A lime soap is formed by this process, which keeps the excess of the oil emulsionized for a short time, the two separating together from the aqueous liquid.

The French Codex directs the separation of the soft saponaceous mass resulting from the agitation of nine parts of lime-water with one part of expressed oil of almonds, and its preservation for use.

Medical Uses.—This liniment is much employed in the treatment of *burns*, both those which are recent and superficial, and those which involve the skin, in their ulcerative stage. It may be used to prevent pitting in confluent *smallpox*. It is applied most efficiently on cloths, which should be kept moist.

LINIMENTUM CAMPHORÆ, *U. S.*, *Br.*—LINIMENT OF CAMPHOR.

Linimentum camphoratum, Oleum camphoratum.—Camphorated oil, E.; *Liniment camphré, Huile camphrée*, Fr.; *Kampferliniment*, G.

Preparation.—Take of Camphor three troyounces; Olive Oil twelve troyounces. Dissolve the camphor in the oil. *U. S.*

Take of Camphor one ounce; Olive Oil four fluidounces. Dissolve the camphor in the oil. *Br.*

A simple solution of camphor in olive oil, which is best obtained by employing the camphor as a fine powder, or by digesting the mixture in a closed bottle at a moderate heat.

Off. Prep.—Linimentum chloroformi, Linim. hydrargyri, Linim. terebinth. acet., *Br.*

Medical Uses.—It is used as an anodyne and discutient application to *sprains*, *bruises*, and *glandular swellings*, and for the relief of *rheumatic pains.* It is also serviceable in preventing the ill effects of pressure by surgical apparatus, and by decubitus.

LINIMENTUM CAMPHORÆ COMPOSITUM, *Br.*—COMPOUND LINIMENT OF CAMPHOR.

Liniment camphré ammoniacal, Fr.; *Ammoniak und Kampfer-Liniment*, G.

Preparation.—Take of Camphor two and a half ounces; Oil of Lavender one fluidrachm; Strong Solution of Ammonia five fluidounces; Rectified Spirit fifteen fluidounces. Dissolve the camphor and oil of lavender in the spirit; then add the solution of ammonia gradually, shaking them together until a clear solution is formed. *Br.*

Medical Uses.—The characteristic of this preparation, as distinguished from simple liniment of camphor, is, that it is rendered stimulant and even rubefacient by the strong water of ammonia it contains. It is a convenient liniment for prescription in cases of local rheumatic, neuralgic, and traumatic pains.

LINIMENTUM CANTHARIDIS, *U. S.*—LINIMENT OF CANTHARIDES.

Huile de cantharides térébenthinée, Fr.; *Spanischfliegen-Liniment*, G.

See also Liquor epispasticus.

Preparation.—Take of Cantharides in fine powder a troyounce; Oil of Turpentine half a pint. Digest the cantharides with the oil for three hours in a close vessel by means of a water-bath, and strain. *U. S.*

Cantharidin is soluble in oil of turpentine; the digestion may be effected in a bottle partly closed by a stopper.

Medical Uses.—This is a very powerful stimulant and counter-irritant preparation. Its advantages over turpentine liniment on the one hand, and over blisters upon the other, are not apparent; and unless carefully used, it may occasion troublesome irritation, and even ulcers.

LINIMENTUM CHLOROFORMI, *U. S.*, *Br.*—LINIMENT OF CHLOROFORM.

Liniment au chloroforme, Fr.; *Chloroform-Liniment*, G.

Preparation.—Take of Purified Chloroform three troyounces; Olive Oil four troyounces. Mix them. *U. S.*

Take of Chloroform, Liniment of Camphor, each two fluidounces. Mix. *Br.*

These preparations are about alike in strength as far as the chloroform is concerned; that by the second formula contains also some camphor. The liniment is readily made extemporaneously, and the camphor, if it is to be contained in it, should be previously dissolved in the chloroform, $\frac{1}{4}$ ounce of camphor being used for every ounce of olive oil.

Medical Uses.—The purpose of this preparation was probably to prolong, and at the same time mitigate, the local anæsthetic action of chloroform. But the object is better accomplished by a mixture of chloroform and soap liniment, to which tincture of aconite root may be added.

LINIMENTUM CROTONIS, *Br.*—LINIMENT OF CROTON OIL.

Liniment crotoné, Fr.; *Krotonöl-Liniment*, G.

Preparation.—Take of Croton Oil one fluidounce; Oil of Cajeput, Rectified Spirit, each $3\frac{1}{2}$ fluidounces. Mix. *Br.*

This is simply a solution of croton oil in alcohol and oil of cajeput, and has the odor of the latter.

Medical Uses.—There is an incongruity in associating a prompt but transient irritant, like oil of cajeput, with one whose operation is slow, and is scarcely active until the characteristic croton pustulation is produced. The preparation has nothing to recommend it before an extemporaneous solution of croton oil in olive oil, with or without the addition of oil of cajeput, cloves, or cassia.

LINIMENTUM HYDRARGYRI, *Br.*—LINIMENT OF MERCURY.

Linimentum mercuriale.—*Liniment mercuriel*, Fr.; *Quecksilber-Liniment*, G.

Preparation.—Take of Ointment of Mercury one ounce; Solution of Ammonia, Liniment of Camphor, of each one fluidounce. Liquefy the ointment of mercury in the liniment of camphor with a gentle heat; then add the solution of ammonia gradually, and mix with agitation. *Br.*

This may be prepared in a wide-mouthed vial, if the ointment and liniment are digested together, and frequently agitated until the lumps have disappeared, when the ammonia water should be added and well incorporated by shaking. The liniment has a gray color from the finely divided mercury.

Medical Uses.—The camphor and ammonia in this preparation are intended by their stimulant action to promote the discutient and absorbent action of the mercury. As it must be applied with friction, there is great danger of its causing salivation. It is less efficient in promoting the resolution of enlarged and indurated glands, etc., than are mercurial ointments and plasters, especially those containing the iodides of mercury.

LINIMENTUM IODI, *Br.*—LINIMENT OF IODINE.

Liniment ioduré, Fr.; *Jodliniment*, G.

Preparation.—Take of Iodine one and a quarter ounce; Iodide of Potassium half an ounce; Camphor a quarter of an ounce; Rectified Spirit ten fluidounces. Dissolve the iodine, iodide of potassium, and camphor in the spirit. *Br.*

This is much stronger than the Tinctura iodi, from which it also differs in containing enough camphor to impart to it its odor. The potassium iodide adapts the liniment for use with aqueous liquids by preventing the precipitation of the iodine.

Medical Uses.—As it is probable that a very minute proportion, if any, either of iodine or of iodide of potassium is absorbed by the sound skin, it must be concluded that this liniment will be less efficient as a local application than either the simple or compound iodine ointment, in both of which the active ingredients are kept longer in contact with the integument than they can be in a liniment.

LINIMENTUM OPII, *Br.*—LINIMENT OF OPIUM.

Anodyne liniment, E.; *Liniment opiacé*, Fr.; *Opiumliniment*, G.

Preparation.—Take of Tincture of Opium, Liniment of Soap, each two fluidounces. Mix.

The *liniment savonneux opiacé* of the French Codex is made by triturating 5 parts of powdered soap with 90 parts of expressed oil of almonds, and adding 5 parts of tincture of opium; it must be well agitated.

Medical Uses.—Being merely a mixture of laudanum and soap liniment, its fixed proportions are rather embarrassing than convenient. The quantity of laudanum used should vary with the condition of the affected part as to delicacy, degree of pain, etc.

LINIMENTUM PLUMBI SUBACETATIS, *U. S.*— LINIMENT OF SUBACETATE OF LEAD.

Liniment saturné, *Beurre de saturne*, *Baume universelle*, Fr.; *Bleiliniment*, G.

Preparation.—Take of Olive Oil three troyounces; Solution of Subacetate of Lead two troyounces. Mix them. *U. S.*

This yields a yellowish-white opaque emulsion, which does not separate on standing, but gradually stiffens. It is made extemporaneously by weighing the materials into a vial and then agitating well.

Medical Uses.—A convenient discutient liniment for *sprains*, *bruises*, *chilblains*, *inflamed glands*, and *chapped hands*.

LINIMENTUM POTASSII IODIDI CUM SAPONE, *Br.*— LINIMENT OF IODIDE OF POTASSIUM AND SOAP.

Liniment savonneux ioduré, Fr.; *Jodkalium-Seifenliniment*, G.

Preparation.—Take of Hard Soap cut small, Iodide of Potassium, each one and a half ounce; Glycerin one fluidounce; Oil of Lemon one fluidrachm;

Distilled Water ten fluidounces. Dissolve the soap in seven fluidounces of the water by the heat of a water-bath. Dissolve the iodide of potassium and glycerin in the remainder of the water, and mix the two solutions together. When the mixture is cold add the oil of lemon and mix the whole thoroughly. *Br.*

The solution of the oil is facilitated by dissolving it in an equal quantity of alcohol previous to mixing it with the aqueous liquid.

Medical Uses.—This liniment is even more objectionable than liniment of iodine, since it contains only the iodic salt and no iodine, as the latter preparation does. The clinical evidence of any real benefit being derived from it through its iodide of potassium has never been furnished. If cutaneous absorption of the iodide of potassium be desired, it will be secured much more readily by the prolonged application of compresses saturated with a strong solution of the iodide, and their protection by a water-proof covering.

LINIMENTUM SAPONIS, *U. S.*, *Br.*—SOAP LINIMENT.

Linimentum saponato-camphoratum liquidum, P. G.—*Liquid opodeldoc*, E.; *Liniment savonneux camphré*, Fr.; *Flüssiger Opodeldok*, G.

Preparation.—Take of Soap in shavings four troyounces; Camphor two troyounces; Oil of Rosemary half a fluidounce; Water six fluidounces; Alcohol two pints. Digest the soap in the water until it is dissolved; dissolve the camphor and oil in the alcohol; mix the solutions, and filter through paper. *U. S.*

Take of Hard Soap cut small two and a half ounces; Camphor one and a quarter ounce; Oil of Rosemany three fluidrachms; Rectified Spirit eighteen fluidounces; Distilled Water two fluidounces. Mix the water with the spirit, and add the oil of rosemary, the soap, and the camphor. Macerate for seven days at a temperature not exceeding 70° F. with occasional agitation, and filter. *Br.*

Both Pharmacopœias use soap made with olive oil and soda, which is more soluble in the alcohol than soap made with animal fat, but both omit to state whether or not the soap is to be dried before being weighed. The details of the first process are rapidly executed; the soap on being digested with the water in a tared vessed yields a thick and smooth, almost jelly-like solution, to which sufficient hot water should be added to compensate for the loss by evaporation; the alcoholic solution of the oil and camphor is then added, the mixture rapidly stirred, and the vessel well closed and allowed to cool. If white Castile soap is used, the liniment will have a pale-yellowish color, and is at once ready for use; but if mottled soap is employed, the preparation will be turbid, and should be filtered, when it will have a brownish color due to the iron held in solution. In very cold weather, two fluidounces of the alcohol may be replaced by the same quantity of water, to prevent a portion of the soap from separating. Barckhausen (1872) suggests the use of a potassa soap made of rape-seed oil, which has the advantage of not separating from the alcohol even at the freezing temperature.

A preparation of similar composition, but differing in consistence, is still employed to some extent and recognized by some Pharmocopœias, as

LINIMENTUM SAPONATO-CAMPHORATUM, s. BALSAMUM OPODELDOC. Opodeldoc, Steer's opodeldoc, *E.;* Baume opodeldoch, Baume de savon, *Fr.;* Opodeldok, *G.*—The French Codex prepares it as follows :—

Digest in a suitable vessel of tallow soap 30 parts, camphor 24 parts, and 90 per cent. alcohol 250 parts; when dissolved add oil of thyme 2 parts, oil of rosemary 6 parts, agitate with 10 parts of animal charcoal, add ammonia water 10 parts, filter rapidly by means of a well-covered funnel, and collect the filtrate in suitable wide-mouth vials.

The German Pharmacopœia uses about two-thirds the weight of soap, and filters before the volatile oils and ammonia have been added. The liniment is solid at the ordinary temperature, but readily liquefies at the temperature of the body, is white or yellowish, opalescent, and somewhat translucent.

SPIRITUS SAPONATUS, P. G.—Seifenspiritus, G., is a solution of one part of Castile soap in 3 parts of alcohol and 2 parts of rose-water.

Medical Uses.—An anodyne and discutient preparation, used for the same purposes as camphor liniment, but more efficient, because more stimulant, than that preparation.

LINIMENTUM SINAPIS COMPOSITUM, *Br.*—COMPOUND LINIMENT OF MUSTARD.

Liniment sinapisé composé, Fr.; *Zusammengesetztes Senfliniment*, G.

Preparation.—Take of Oil of Mustard one fluidrachm; Ethereal Extract of Mezereon forty grains; Camphor one hundred and twenty grains; Castor Oil five fluidrachms; Rectified Spirit four fluidounces. Dissolve the extract of mezereon and camphor in the spirit, and add the oil of mustard and castor oil. *Br.*

The solution is readily effected on maceration in a vial.

Medical Uses.—It was doubtless intended in this compound to provide a powerful counter-irritant and revulsive, and it is described as a useful embrocation. We should hesitate to employ it without feeling more assured than at present of its being safe. The sores made by mezereon or by mustard are very intractable. Moreover, if the oil of mustard is in such proportion as to produce its proper effect, it will do so long before the mezereon has begun to act. Hence one or the other ingredient of the liniment would seem to be superfluous.

LINIMENTUM TEREBINTHINÆ, *U. S.*, *Br.*—LINIMENT OF TURPENTINE.

Liniment térébenthiné, Fr.; *Terpentinliniment*, G.

Preparation.—Take of Resin Cerate twelve troyounces; Oil of Turpentine half a pint. Add the oil to the cerate previously melted, and mix them. *U. S.*

Take of Soft Soap two ounces; Camphor one ounce; Oil of Turpentine sixteen fluidounces. Dissolve the camphor in the oil of turpentine, then add the soap, rubbing them together until they are thoroughly mixed. *Br.*

The first formula yields what is known as *Kentish liniment;* the cerate should be melted at a low heat, and then the oil gradually added with continued stirring. The second process is a considerable modification of the former, and requires continued trituration of the soap in a mortar, with the gradual addition of the oil, in order to obtain a uniform mass.

Medical Uses.—This preparation was originally employed in the treatment of *burns* and *scalds*, which it protects from the irritating influence of the air, while it maintains a moderate stimulation which tends to prevent the ulterior effects of those injuries. It is essential for its successful use that the primary dressing should not be removed for twenty-four hours, and that the liniment should not be continued longer than is necessary to establish a healthy action in the part. This preparation is also serviceable in superficial *erysipelas*, or *erythema*, arising from traumatic causes, and in *frost-bite* without active inflammatory phenomena.

LINIMENTUM TEREBINTHINÆ ACETICUM, *Br.*—LINIMENT OF TURPENTINE AND ACETIC ACID.

Liniment térébenthiné acétique, Fr.; *Terpenthin- und Essig-Liniment*, G.

Preparation.—Take of Oil of Turpentine, Acetic Acid, Liniment of Camphor, each one fluidounce. Mix. *Br.*

Medical Uses.—This preparation is essentially "St. John Long's liniment," which name it derived from a quack who professed to cure almost every painful local disease by its application. It is particularly efficient in *neuralgia* when applied over the points of exit of the trunks, or the terminal distribution of the affected nerves. It should then be employed so as to vesicate the part superficially and over a small area. It may also be applied to relieve other local pains and inflammations, such as limited *muscular rheumatism*, and to the epigastrium to allay *vomiting* depending on inflammation of the stomach.

LINUM, *U. S.*—FLAXSEED.

Lini semina, Br.; *Semen Lini*, P. G.—*Linseed*, E.; *Semence de lin*, Fr.; *Leinsamen*, *Flachssamen*, G.

The seed of Linum usitatissimum, *Lin.* Woodv., Med. Bot., plate 3; Bentley and Trimen, Med. Plants, 39.

Nat. Ord.—Linaceæ.

LINI FARINA, *U. S.*, *Br.*—FLAXSEED MEAL.

Linseed meal, E.; *Farine de lin*, Fr.; *Leinsamenmehl*, G.

Origin.—Flax is probably indigenous to the Mediterranean basin, but has been cultivated for so long a period, and grows so spontaneously wherever it has been introduced, that it is difficult to determine its native country. It has an annual stem about 2 feet high, alternate linear-lanceolate leaves, and terminal flowers with 5 ovate pointed and 3-nerved sepals, and 5 fugacious blue-veined and short-clawed petals. The fruit is an ovate 5-celled and 10-seeded capsule, each cell being again imperfectly divided. As cultivated in the various tropical and temperate countries, several varieties have been observed differing in the shape and size of the seeds, and more markedly in other characters. The seeds are principally imported from Russia and Germany.

Fig. 99.

Flaxseed.—*a.* Entire. *b.* Section through the epithelium, testa, and tegmen to the albumen.

Description.—Flaxseed is about $\frac{1}{6}$ inch long, oblong-ovate, considerably flattened, rounded below, and oblique at the apex, beneath which the hilum is located in a slight depression. The testa is of a brown color, glossy, and covered with a transparent epithelium, which swells very considerably in water; the kernel consists of a very thin endosperm and two large plano-convex oily cotyledons having the shape of the seed, with the radicle projecting into the pointed end. The seed is inodorous, and has a mucilaginous, bitterish, and oily taste.

Lini farina, U. S., is the meal obtained from flaxseed, containing the oil. The British Pharmacopœia recognizes by the same name the meal which has been deprived of the oil by pressure.

Constituents.—The most important constituents of flaxseed are the *mucilage* and *fixed oil*, the latter (see Oleum lini), according to Chevallier (1844), being contained in the embryo to the extent of about 30 to 39 per cent., the former in the epithelium to the extent of about 15 per cent. The mucilage is $C_{12}H_{20}O_{10}$, and by nitric acid is converted into mucic acid. Besides the above, Leo Meyer (1826) found protein compounds, a small portion of wax, resin, sugar, malates, acetates, and other salts, which are dissolved with the mucilage. The ash amounts to about 3 per cent., and consists of phosphates with some sulphates and chlorides of potassium, calcium, and magnesium.

Off. Prep.—1. Of flaxseed: Farina lini, Infus. lini comp. (lini), *U. S.*, *Br.* 2. Of flaxseed meal: All cataplasms, except Catapl. fermenti, *Br.*

Medical Action and Uses.—The union of oil and mucilage in flaxseed adapts it for external application in the many cases in which an emollient is required; and the ready absorption of its infusion has led to its internal use as a diluent and diuretic. Flaxseed tea is universally employed in *inflammations* of mucous membranes of the respiratory, digestive, and urinary organs. It serves as the basis of numerous ptisans, and is injected into the rectum, vagina, and bladder, in irritations of those organs. It forms an ordinary drink in *renal* and *vesical* irritations. The tea is made with half an ounce of flaxseed to a pint of boiling water, macerated for two hours, and strained. It may be taken in any convenient quantity. The compound infusion, which is officinal, contains liquorice, which adapts it to bronchial affections. Flaxseed mucilage is prepared by boiling the seed. It is commonly used to cover *erysipelatous* and other inflammations of the skin, *burns*, etc., but is objectionable if allowed to get dry, by rendering the skin stiff; it is also apt to become sour and irritating. For the purposes last mentioned the acetate of lead is sometimes dissolved in it. It precipitates the solution of subacetate of lead.

The flaxseed poultice is prepared by gradually pouring boiling water upon flaxseed meal, and stirring the mixture until it acquires the proper consistence. As it tends to render the skin white, wrinkled, and sodden, and to excite a pustular eruption, the part to which it is applied should first be covered with sweet oil, fresh lard, or glycerine; or as directed officinally (British Pharmacopœia), olive oil should be mixed with the meal of which the poultice is made.

LINTEUM.—Lint.

Linteum carptum.—*Charpie*, Fr. G.

Preparation and Description.—Lint was originally made from bleached linen cloth by scraping it until it became soft and woolly. At the present time it is almost exclusively prepared by means of machinery from a fabric woven for this purpose, and is known as *patent lint*, in distinction to the hand-made lint. It is in rather thick, but very soft and fleecy sheets, and, when viewed under the microscope, shows the bast cells of flax as long cylindrical tubes, which are slightly thickened in a few places, and somewhat pointed towards both ends. The cell-walls are very thick by concentric deposits, leaving only a small central cavity. Immersed in an ammoniacal solution of copper, they swell considerably, and are ultimately dissolved without leaving any residue. These cells resemble the bast fibres of hemp, but the latter are thinner, blunt at the ends, with a still smaller cavity in the centre, and adhere more firmly together, hence the coarser appearance of hemp fabrics.

Cotton is now often more or less substituted for linen, and lint made in this way is known as *cotton lint*. The fibre of cotton is described on page 679, and may be readily distinguished from linen fibre by the microscope.

Tests for Linen and Cotton.—Boiled with a concentrated solution of potassa, the linen fibre turns bright yellow within two minutes, while cotton fibre remains white or becomes pale yellowish. Dipped in a solution of *rosolic acid*, which is known in commerce as aurin or yellow corallin, and afterwards in a concentrated solution of sodium carbonate, linen fibre is dyed rose-red, while cotton fibre remains white. When immersed in a tincture of *madder*, linen fibre acquires a yellowish-red, but cotton fibre a light yellow color. Cold concentrated *sulphuric acid* does not materially alter linen fibre within one or two minutes, while cotton fibre is destroyed in the same time. When rubbed with a *fixed oil*, linen fabric remains white and opaque, but cotton becomes translucent.

Surgical Action and Uses.—The purpose of lint is to provide a soft, unirritating covering for wounds; to protect them from the air and the foreign particles floating in it; to moderate and graduate the pressure of bandages and other surgical apparatus; to absorb the more liquid discharges; and to be introduced into wounds which are not intended to heal immediately. Of the different forms of lint, that which is made of old linen by picking apart its threads is the most elastic and absorbent, and by far the most comfortable to the patient; that which is made by scraping old linen is very suitable for small wounds and abrasions; and the so-called patent lint is the least eligible unless its threads are unravelled so as to form a soft mass. But the last mentioned lint, when made of cotton, as it usually is, does not absorb discharges nearly as well as that derived from linen, chiefly on account of the oil which adheres to it. Of late years cotton has been prepared entirely free from oil, and therefore possessing a greater absorbent power, and is at the same time impregnated with carbolic acid so as to render it disinfectant. But a defect of all cotton lint is that as soon as it becomes saturated with liquids it entirely loses its elasticity, which is not the case with old linen lint, or charpie. A substance analogous to charpie is oakum, which consists of tarred ropes picked into shreds, and whose value derived from the tar impregnating it is counterbalanced by the harshness of the material.

LIQUIDAMBAR.—Sweet Gum.

A balsamic exudation from Liquidambar styraciflua, *Lin.*

Nat. Ord.—Hamamelaceæ, Balsamifluæ.

Origin.—The sweet gum tree is a large and handsome North American tree, growing from Connecticut and Illinois southward and westward to Mexico. It has a thick gray deeply furrowed astringent bark, that of the branches being usually furnished with thick, wing-like ridges of cork. The leaves are dark green, round in outline, palmately five to seven-lobed, and the lobes serrate. The fruit is capsular, beaked, aggregated in globular heads, together with the indurated scales. The leaves, fruit and bark when bruised have an agreeable odor; the taste of the bark is balsamic and astringent, and that of the other parts mentioned aromatic and acidulous. In its southern locations the tree yields a balsamic exudation from incisions made in the bark.

Description.—Sweet gum, also called *gum wax*, exudes in the form of a thick liquid, having the density of syrup, and a yellowish color. On standing it thickens, becomes darker in color, and finally hard at the ordinary temperature, and breaks with a resinous fracture, which is of a variegated appearance, the color being brown, with lighter and even white spots and streaks. It softens somewhat by the warmth of the hand, and when heated fuses to a yellowish-brown liquid. It has a very pleasant balsamic odor and taste, the latter being followed by pungency. It dissolves completely, fragments of bark excepted, in alcohol, ether, and chloroform; the alcoholic solution having a slight acid reaction.

Constituents.—A pretty complete analysis of sweet gum was made by Wm. L. Harrison (1874). He obtained, by distillation with a solution of sodium carbonate in water, $3\frac{1}{2}$ per cent. of an aromatic oily hydrocarbon, having the properties of *styrol*, and the aqueous liquid in the retort, on being supersaturated with acid, yielded $5\frac{1}{2}$ per cent. of *cinnamic acid*. The portion insoluble in the alkaline liquor was partly dissolved in hot petroleum-benzin, the solution yielding *styracin* on cooling, and finally left a dark brown nearly colorless and inodorous resin. The sweet gum examined contained 9 per cent. of impurities. On treating sweet gum with warm petroleum-benzin, cinnamic acid and styracin are taken up, and crystallize together on cooling; they may then be separated with weak ammonia, which dissolves the cinnamic acid only. Harrison observed also that by heating sweet gum with a small quantity of water, and stirring frequently, a gray-colored mixture is obtained resembling storax. The presence of cinnamic acid in sweet gum was previously proved by Hanbury (1857) and Procter (1866). It will be observed that sweet gum agrees in composition with storax, which, in addition, contains water mechanically mixed with it.

Pharmaceutical Uses.—A *syrup of sweet gum* is made by the officinal process for syrup of tolu, and is much employed in some parts of the Southern States. A *syrup of sweet gum bark* is likewise used and prepared by the officinal process for syrup of wild cherry (Dr. C. W. Wright, 1856). According to L. Hughes (1876), an ethereal solution of sweet gum is very serviceable for extinguishing the mercury in preparing mercurial ointment.

Medical Action and Uses.—These appear to be identical with those of storax; and indeed the latter is defined by the United States Pharmacopœia to be "a balsam prepared from the bark of Liquidambar orientale." Its action is that of an aromatic resin, operating particularly upon the respiratory and urinary mucous membranes. It is employed in the treatment of chronic profluvia of these parts, such as *bronchitis*, *cystitis*, *pyelitis*, and *gleet*. Externally it was used formerly in an ointment for the treatment of *scabies*, and for various purposes to which resin cerate is now applied, including frost-bite, indolent *ulcers*, and *burns*.

LIQUORES.—SOLUTIONS.

Solutés, Fr.; *Lösungen*, G.

With the exception of infusions, decoctions, and syrups, and of those aqueous liquids containing volatile oils or gases, all aqueous solutions are, by the U. S. Pharmacopœia, designated *Liquores;* the British and some other Pharmacopœias embrace under the same head also aqueous solutions of gases. The German Pharmacopœia is inconsistent in its designation; lime-water, chlorine water, and some lotions being placed among *Aquæ*, while ammonia water is regarded as a *liquor*. Gutta-percha solution and blistering liquid alone have a menstruum other than water.

LIQUOR AMMONIÆ, *Br.* See AQUA AMMONIÆ.

LIQUOR AMMONII ACETATIS, *U. S.*—SOLUTION OF ACETATE OF AMMONIUM.

Liquor ammoniæ acetatis, Br.; *Liquor ammonii acetici*, P. G.; *Acetas ammonicus liquidus*, *Spiritus Mindereri.—Spirit of Mindererus*, E.; *Acetate d'ammoniaque liquide*, *Esprit de Mindererus*, Fr.; *Essigsaure Ammonium-Flüssigkeit*, G.

Preparation.—Take of Diluted Acetic Acid two pints; Carbonate of Ammonium a sufficient quantity. Add the carbonate gradually to the acid until the latter is neutralized, and filter. This preparation, when dispensed, should be freshly made.

Solution of acetate of ammonium may also be prepared by mixing together the following solutions :—

Take of Carbonate of Ammonium six hundred and forty grains; Distilled Water a sufficient quantity. Dissolve the carbonate of ammonium in twelve fluidounces of distilled water, and filter through paper, adding a sufficient quantity of distilled water, through the filter, to make the solution measure a pint.

Take of Acetic Acid four fluidounces; Distilled Water twelve fluidounces. Mix them.

These solutions must be kept in well-stopped bottles, and mixed in equal quantities when dispensed. *U. S.*

Take of Acetic Acid ten fluidounces; Carbonate of Ammonia three and a quarter ounces or a sufficiency; Distilled Water two and a half pints. Reduce the carbonate of ammonia to powder, and add it gradually to the acetic acid, until a neutral solution is formed, then add the water. *Br.*

The directions of the U. S. Pharmacopœia indicate that the solution is to contain some carbonic acid. The first formula directs the *neutralization* of the acetic acid, which, however, cannot be ascertained by litmus paper, owing to the carbonic acid remaining in solution. Turmeric paper is preferable, in so far as it more readily indicates even a slight excess of ammonium carbonate by the brown color produced; but the exact point of neutralization cannot be ascertained. Under the circumstances the taste is as reliable as test-paper. After the pricking sensation upon the tongue caused by the carbonic acid has disappeared, the taste should be saline, and free from alkalinity. This result is accomplished by the second process, provided that translucent ammonium carbonate is used in making one of the solutions. The correct measures of the alkaline and acid solutions having been taken, they are mixed in a graduate, and after the violent effervescence has subsided the liquid is poured into the vial.

The British Pharmacopœia directs the preparation of a neutral solution which is somewhat stronger; the undiluted acetic acid being used, less carbonic acid is retained by the liquid, and may be expelled by trituration or stirring at first, and towards the close of the reaction by warming the liquid until it has no effect upon test-paper, after which it is to be properly diluted. In place of ammonium carbonate ammonia water may be used to effect the neutralization, as directed by the German Pharmacopœia.

Acetic acid decomposes ammonium carbonate, carbonic acid gas being given off, and ammonium acetate remaining in solution; $4HC_2H_3O_2 + N_4H_{16}C_3O_8$ yields $3CO_2 + 4NH_4C_2H_3O_2 + 2H_2O$. When long kept in contact with air, the solution acquires an alkaline reaction.

Physiological Action.—Experiments upon animals show that this preparation, in large doses, affects them energetically; in rabbits causing fatal tetanic spasms and dissolution of the gastric mucous membrane. Given to healthy men it does not appear to occasion any decided symptoms—only a little warmth of the skin and in the abdomen, headache, and loss of appetite. Upon the skin it acts as an irritant, and may even vesicate it. Judged by its apparent effects in disease, it seems to be diaphoretic, diuretic, and expectorant, sometimes causing transient giddiness and exhilaration.

Medical Uses.—It is generally held to be efficient in the forming stage of *catarrh*, *sore throat*, and *muscular rheumatism*, and in the *eruptive fevers* when the eruption is slow to appear. It is the best diaphoretic in epidemic catarrh or *influenza*. In low forms of *fever* it is often of signal advantage, helping to sustain the powers of life until the crisis is past. In this way it is peculiarly valuable in *typhus*, in which, like other appropriate stimulants, it lowers the pulse and temperature, moistens the dry tongue, and moderates the delirium.

It is reported to have been peculiarly efficacious in the treatment of epidemic *pseudo-membranous bronchitis.*

In *sick headache* few remedies are so successful as a teaspoonful or two of this solution repeated every hour. In *alcoholic intoxication* it frequently dissipates at once the signs of drunkenness. It is reported to be an efficient remedy in *dysmenorrhœa* and *menorrhagia.* It is an adjuvant in the treatment of scarlatinous *dropsy*, and is, perhaps, not without advantage in chronic *eruptions of the skin.*

Externally it is a valuable discutient in *contusions, glandular swellings, mammary engorgements, commencing abscesses, hydrarthrosis*, and even acute *hydrocele.* It has been found beneficial in *impetigo capitis.*

The *dose* of the officinal solution is from half a fluidounce to a fluidounce and a half, diluted with sweetened water.

LIQUOR AMMONIÆ CITRATIS, *Br.*—SOLUTION OF CITRATE OF AMMONIA.

Citrate d'ammoniaque liquide, Fr.; *Citronensaure Ammoniak-Flüssigkeit*, G.

Preparation.—Take of Citric Acid three ounces; Strong Solution of Ammonia two and three-quarter fluidounces or a sufficiency; Distilled Water one pint. Dissolve the citric acid in the water, and add the solution of ammonia until the liquid is neutral to test-papers. *Br.*

Citric acid $H_3C_6H_5O_7$ unites with ammonia $3HNH_4O$ to form ammonium citrate $(NH_4)_3C_6H_5O_7$ and water $3H_2O$. The point of neutralization is ascertained by blue litmus paper, which should not be reddened, and by turmeric paper, which should not acquire a brownish tint. The solution is clear and colorless, and has a saline taste.

Medical Action and Uses.—This solution is perhaps more palatable than solution of acetate of ammonia, but its medicinal effects are in no wise different. *Dose*, from two to four fluidrachms.

LIQUOR ANTIMONII CHLORIDI, *Br.*—SOLUTION OF CHLORIDE OF ANTIMONY.

Liquor Stibii chlorati, P. G.; *Antimonium muriaticum liquidum, Butyrum antimonii (s. stibii), Chloridum (s. Chloruretum) stibicum.—Liquid butter of antimony*, E.; *Chlorure (Beurre) d'antimoine liquide, Huile d'antimoine*, Fr.; *Spiessglanzbutter*, G.

Preparation.—Take of Black Antimony one pound; Hydrochloric Acid four pints. Place the black antimony in a porcelain vessel, pour upon it the hydrochloric acid, and constantly stirring, apply to the mixture, beneath a flue with a good draught, a gentle heat, which must be gradually augmented as the evolution of gas begins to slacken, until the liquid boils. Maintain it at this temperature for fifteen minutes; then remove the vessel from the fire, and filter the liquid through calico into another vessel, returning what passes through first, that a perfectly clear solution may be obtained. Boil this down to the bulk of two pints (imperial), and preserve it in a stoppered bottle. *Br.*

Hydrochloric acid decomposes sulphide of antimony with the production of antimonious chloride which dissolves in the acid liquid, and hydrogen sulphide which escapes; $Sb_2S_3 + 6HCl$ yields $2SbCl_3 + 3H_2S$. Provision must be made to carry off the offensive gas either through a flue or by working in the open air. The powdered sulphide and the acid may be left in contact for several hours, during which time the reaction will partly take place; the mixture should afterwards be slowly heated until the boiling point is reached, and the disengagement of sulphuretted hydrogen ceases. The insoluble mineral impurities are then filtered off, either through calico, or preferably through a material which is not corroded by the acid liquid, such as gun-cotton, asbestos, or glasswool. The arsenic naturally contained in the antimony is partly evolved, and the remainder is removed as arsenious chloride by boiling the filtered liquid and concentrating it as directed, this arsenic compound being much more volatile than the antimonious chloride.

Properties.—It is a yellowish or yellowish-red liquid, having the spec. gr. 1.47, and yielding with water a white precipitate of antimonious oxychloride (*powder of Algaroth*), $(SbCl_3)_2 5Sb_2O_3$. This precipitate is completely soluble in an aqueous solution of tartaric acid, and the solution, when treated with hydrogen sulphide, yields an orange-brown precipitate of sulphide of antimony, which, after drying, should weigh not less than 22 grains for every fluidrachm of the officinal solution. When free from other metals the solution is colorless; as prepared from the crude sulphide, however, it always contains ferric chloride.

Impurities.—*Lead*, if present, will mostly crystallize from the cold liquid; what remains dissolved may be recognized by a drop of dilute sulphuric acid, which will cause a white precipitate. *Copper* is recognized by the blue color obtained on treating the liquid with an excess of ammonia. *Arsenic* is detected by rendering the liquid strongly alkaline with potassa, adding a little pure zinc, and heating to boiling. The vapors on coming in contact with filtering paper, moistened with a drop of solution of silver nitrate, will then color the latter black.

Pharmaceutical Uses.—In the preparation of Antimonii oxidum, *Br.*

Surgical Action and Uses.—Butter of antimony is one of the most powerful caustics used in surgery, and, from its readily penetrating into *wounds*, it has been used to cauterize those inflicted by rabid animals and venomous serpents. It has also been applied to *malignant pustule*, *warts*, *condylomata*, and *chancres*. "Pure chloride of antimony has been used as an application to staphyloma by some German surgeons; a camel's-hair pencil or a point of lint is dipped in the deliquescent salt and applied to the tumor until a whitish crust is perceived, when the whole is washed away by means of a large camel's-hair pencil dipped first in milk and afterwards into milk and water." (Neligan.)

Several instances of poisoning by this preparation are on record in which, besides abrasions of the mouth and throat, or even a charred appearance of these parts, there was more or less complete general collapse. In one case recovery took place after four or five drachms, and in another after an ounce, had been taken. In a fatal case the dose was three ounces, and on inspection after death the interior of the alimentary canal from the mouth downwards to the jejunum presented a black appearance, as if the parts had been charred. (Taylor.)

The proper antidotes for poisoning by chloride of antimony are chalk, and magnesia or its carbonates, combined with demulcent drinks. Tannic acid and the substances containing it are also recommended.

LIQUOR ARSENICALIS, *Br.* See LIQUOR POTASSII ARSENITIS.

LIQUOR ARSENICI CHLORIDI, *U. S.*—SOLUTION OF CHLORIDE OF ARSENIC.

Liquor arsenici hydrochloricus, Br.—*Hydrochloric solution of arsenic*, E.; *Liqueur arsenicale hydrochlorique*, Fr.; *Chlorarsenik-Lösung*, G.

Preparation.—Take of Arsenious Acid in small pieces sixty-four grains; Muriatic Acid two fluidrachms; Distilled Water a sufficient quantity. Boil the arsenious acid with the muriatic acid and four fluidounces of distilled water, until the arsenious acid is entirely dissolved, and, when the solution is cold, add enough distilled water to make it measure a pint. *U. S.*

Take of Arsenious Acid in powder eighty grains; Hydrochloric Acid two fluidrachms; Distilled Water a sufficiency. Boil the arsenious acid with the hydrochloric acid and four ounces of the water until it is dissolved; then add distilled water to make the bulk up to one pint (imperial). *Br.*

Arsenious and hydrochloric acids, when heated together, and then distilled, unite to form volatile *arsenious chloride*, As_2Cl_6, which, on being dissolved in water, is decomposed again into the compounds from which it was prepared. The officinal solutions, therefore, contain simply the two acids.

Properties.—The solution is colorless, has an acid reaction, and the spec. grav. 1.009. Sulphuretted hydrogen yields at once a bright yellow precipitate of sulphide of arsenic. In arsenic strength it corresponds with Fowler's solution, containing 4 grains to the fluidounce; De Valangin's solution contained $1\frac{3}{4}$ grains. The British Pharmacopœia gives the following directions for determining its strength. One fluidounce boiled for five minutes with twenty grains of bicarbonate of soda, and then diluted with six fluidounces of distilled water, to which a little mucilage of starch has been added, does not give with the volumetric solution of iodine a permanent blue color until 808 grain-measures have been added.

Medical Uses.—The advantages of this preparation, which is known as Valangin's solution, over Fowler's solution, are far from being apparent. Indeed, its action has been pronounced very uncertain. Its medicinal uses and its *dose* are the same as those of the latter preparation.

LIQUOR ARSENICI ET HYDRARGYRI IODIDI, *U. S.* —SOLUTION OF IODIDE OF ARSENIC AND MERCURY.

Solutio Donovani.—Donovan's solution, E.; *Soluté d'iodo-arsénite de mercure, Liqueur de Donovan*, F.; *Jodquecksilber-Arsenik-Lösung, Donovansche Tropfen*, G.

Preparation.—Take of Iodide of Arsenic, Red Iodide of Mercury, each thirty-five grains; Distilled Water half a pint. Rub the iodides with half a fluidounce of the water, and, when they are dissolved, add the remainder of the water, and filter through paper. *U. S.*

This is a solution of the two iodides in very nearly the proportion of their molecular weights, and containing them mixed, but not chemically combined.

Properties.—It is of a light yellow color, has a metallic taste, and gives precipitates with solutions of silver, alkalies, and salts of the alkaloids. The 8 fluidounces represent very nearly 6 grains of metallic arsenic, and 15.5 grains of mercury.

Medical Uses.—The combination of arsenic and mercury in this preparation was made for the treatment of *syphilitic* diseases of the skin, and is especially useful in those of the squamous form, although mercury alone is apt to aggravate them. Many consider that in these cases the mercury is more injurious than useful. Its efficacy is shown in other cutaneous affections apparently free from syphilitic taint, when they have become chronic, and have resisted arsenic alone. Among these may be mentioned *impetigo* and *sycosis;* in the latter it should be associated with epilation. The best authorities deny that it has any curative influence in *lupus*. The *dose* is five drops, gradually increased, and should be taken after meals, well diluted.

LIQUOR ATROPIÆ, *Br.*—SOLUTION OF ATROPIA.

Soluté d'atropine, Fr.; *Atropin-Lösung*, G.

Preparation.—Take of Atropia four grains; Rectified Spirit one fluidrachm; Distilled Water seven fluidrachms. Dissolve the atropia in the spirit, and add this gradually to the water, shaking them together. *Br.*

Medical Uses.—This solution contains in each minim the one hundred and twentieth of a grain of atropia. It may be used hypodermically in the dose of one minim, and cautiously increased. It is used for dilating the pupil by instilling it into the eye, care being taken, by pressure on the puncta lachrymalia, to prevent its passage into the nostril.

LIQUOR ATROPIÆ SULPHATIS, *Br.*—SOLUTION OF SULPHATE OF ATROPIA.

Soluté de sulfate d'atropine, F.; *Schwefelsaure Atropinlösung*, G.

Preparation.—Take of Sulphate of Atropia four grains; Distilled Water one fluidounce. Dissolve. *Br.*

The two preceding solutions are best prepared in small quantity only, that decomposition, which is likely to result from long keeping, may be prevented.

Medical Uses.—This preparation is identical with solution of atropia in its strength, action, uses, dose, and mode of application. For acting upon the iris, disks of paper or gelatin impregnated with either solution may be introduced between the eyelid and the eyeball.

LIQUOR BARII CHLORIDI, *U. S.*—SOLUTION OF CHLORIDE OF BARIUM.

Soluté de chlorure de baryum, Fr.; *Chlorbaryum-Lösung*, G.

Preparation.—Take of Chloride of Barium a troyounce; Distilled Water three fluidounces. Dissolve the chloride in the distilled water and filter through paper. *U. S.*

Properties.—A colorless solution having the disagreeable taste of barium salts. It is precipitated by solutions of sulphates and carbonates, and of most salts of organic acids, except the acetates.

Medical Uses.—It is difficult to understand why a preparation in favor of whose therapeutic virtues so little can be said, should continue to be employed in medicine, and distinguished by an officinal rank. Under Barium will be found a more detailed account of it.

LIQUOR BISMUTHI ET AMMONIÆ CITRATIS, *Br.*—SOLUTION OF CITRATE OF BISMUTH AND AMMONIA.

Liquor bismuthi.—Solution of ammonio-citrate of bismuth, E.; *Soluté de citrate de bismuth ammoniacal*, Fr.; *Citronensaure Wismuth-Ammoniak-Lösung*, G.

Preparation.—Take of Purified Bismuth four hundred and thirty grains; Nitric Acid two fluidounces; Citric Acid two ounces; Solution of Ammonia, Distilled Water, each a sufficiency. Mix the nitric acid with an ounce of distilled water, and add the bismuth in successive portions. When effervescence has ceased, apply for ten minutes a heat approaching that of ebullition, and decant the solution from any insoluble matter that may be present. Evaporate the solution until it is reduced to two fluidounces, then add the citric acid previously dissolved in four ounces of distilled water, and afterwards the solution of ammonia in small quantities at a time until the precipitate formed is redissolved, and the solution is neutral or slightly alkaline to test-paper. Dilute with distilled water to the volume of one pint (imperial). *Br.*

A strong solution of bismuthous nitrate is first produced by dissolving the metal in nitric acid and concentrating by evaporation. Twice the weight of citric acid is then added, or enough to convert the whole of the bismuth into bismuthous citrate, and to leave an equal weight in excess. On adding ammonia to the acid liquid, ammonium citrate is formed, and this reacting with the bismuth salt, bismuthous citrate is thrown down: $(NH_4)_3C_6H_5O_7 + Bi3NO_3$ yields $BiC_6H_5O_7 + 3NH_4NO_3$. Without filtering, more ammonia is supplied to produce an additional quantity of ammonium citrate, which is supposed to unite with the bismuthous citrate to form the double salt, the citrate of bismuth and ammonium, $BiC_6H_5O_7.(NH_4)_3C_6H_5O_7$, in addition to which the solution contains ammonium nitrate. N. G. Bartlett (1865), however, showed, and his observations were corroborated by Méhu (1873), that the neutral bismuthous citrate dissolves in ammonia, and that on evaporation, a dry salt is obtained which is again soluble in water, and for which Rother (1876) gives the formula $(NH_4)_3C_6H_5O_7.Bi3HO$. These observations have led to several modifications of the above formula, by which contamination with ammonium nitrate is at the same time avoided. These modifications are based upon the preparation of *bismuth citrate;* 1, by double decomposition between bismuth nitrate and potassium or sodium citrate; or 2, by first preparing bismuthous hydrate or subcarbonate, and treating this with the equivalent quantity of citric acid; or 3, as suggested by Rother, by boiling for a short period equivalent quantities of (10 parts) bismuth subnitrate and (7 parts) citric acid with some water, washing the precipitate, and dissolving in ammonia.

Properties.—The solution of the British Pharmacopœia is colorless, has a saline slightly styptic taste, and the specific gravity 1.122. It is neutral or slightly alkaline to test-paper, and mixes with water without change. Potassa yields a precipitate of bismuth hydrate, and liberates ammonia; muriatic acid produces a precipitate of basic salt which is redissolved by an excess of acid. Three fluidrachms of the officinal solution, treated with sulphuretted hydrogen, yield a black precipitate, which, after drying, weighs 9.92 grains. Each fluidrachm represents 3 grains of bismuthous oxide.

BISMUTHI ET AMMONII CITRAS.—Ammonio-citrate of bismuth, *E.;* Citrate de bismuth ammoniacal, *Fr.;* Citronsaures Wismuthammoniak, *G.*

As stated above, the officinal solution contains ammonium nitrate and an excess of ammonium citrate. It is, therefore, not adapted to the preparation of the dry salt. But if the *bismuth citrate* prepared by either of the above processes is dissolved in ammonia, the solution carefully concentrated and dried, the salt is obtained in white, transparent shining scales, which are freely soluble in water, slightly so in alcohol, and insoluble in ether, and have a slightly acid and metallic taste. Exposed to air, it loses ammonia, becomes opaque, and then dissolves in water only after the addition of a little ammonia. According to Rother, it is anhydrous, and should therefore yield 46.4 per cent. of bismuthous oxide.

Medical Uses.—If, as we have endeavored to show elsewhere, the action of bismuth is entirely local and depends upon its insolubility, the use of its soluble salts is irrational. Yet the solubility of this preparation is set forth as a ground of its superiority over the oxide and the subnitrate! The officinal *dose* is stated to be from thirty minims to one fluidrachm.

LIQUOR CALCII CHLORIDI, *U. S.*—SOLUTION OF CHLORIDE OF CALCIUM.

Soluté de chlorure de calcium, Fr.; *Chlorcalcium-Lösung*, G.

Preparation.—Take of Marble in small pieces six troyounces; Muriatic Acid twelve troyounces; Distilled Water a sufficient quantity. Mix the acid with half a pint of distilled water, and gradually add the marble. Towards the close of the effervescence apply a gentle heat, and, when the action has ceased, pour off the clear liquid, and evaporate to dryness. Dissolve the residue in one and a half times its weight of distilled water, and filter through paper. *U. S.*

The preparation of calcium chloride and its purification from iron have been explained (see Calcii chloridum, p. 317). In the above process the solution is directed to be evaporated to dryness; if the temperature does not exceed 150° C. (302° F.) the residue is a hydrate of the formula $CaCl_2.2H_2O$, and molecular weight 147. This is dissolved in 1½ times its weight of distilled water, so that 10 parts of the solution contain 4 parts of the salt mentioned, or 3 parts of the anhydrous calcium chloride. (For properties and tests see page 317.)

Pharmaceutical Uses.—In the preparation of Calcii carbonas præcip., *U. S.*

Medical Action and Uses.—This solution is an active irritant, and may readily become poisonous. It was formerly used in *scrofula*, *goitre*, and *cutaneous eruptions*, but is now deservedly abandoned. The *dose* is said to be thirty or more minims, and should be given in milk or sweetened water.

LIQUOR CALCIS, *U. S.*, *Br.*

Aqua calcariæ, P. G.; *Aqua calcariæ ustæ*, *Aqua calcis*, *Calcaria soluta*, *Oxydum calcicum aqua solutum.*—*Solution of lime*, *Lime water*, E.; *Eau (Liqueur) de chaux*, Fr.; *Kalkwasser*, G.

Preparation.—Take of Lime four troyounces; Distilled Water eight pints. Upon the lime, first slaked with a little of the distilled water, pour the remainder of the water, and stir them together. Then immediately cover the vessel, and set it aside for three hours. Keep the solution, together with the undissolved lime, in a well-stopped bottle, and pour off the clear liquid when wanted.

Water free from saline or other obvious impurity, though not distilled, may be employed in this process. *U. S.*

Take of Slaked Lime two ounces; Distilled Water one gallon. Put the lime into a stoppered bottle containing the water, and shake well for two or three minutes. After twelve hours the excess of lime will have subsided, and the clear solution may be drawn off with a siphon as it is required for use, or transferred to a green glass bottle furnished with a well-ground stopper. *Br.*

When water is added to burned lime or calcium oxide, it is converted into *calcium hydrate* Ca2HO, molec. weight 74, which dissolves in the excess of water. If used for this purpose the lime should be prepared from marble, when it will be nearly pure; but if made from ordinary limestone, it usually contains alkalies which are readily soluble in water; hence it should be treated with a portion of the water, and this rejected to remove the impurities mentioned. The water should be kept upon the lime to retain the solution saturated, and this should be drawn off as needed. Since at the ordinary temperature lime requires about 750 parts of water for solution, one fluidounce (U. S. measure) of lime-water contains 0.6 grain of lime, or 0.8 grain of calcium hydrate.

Properties.—Lime-water is a clear, colorless solution, of a slight alkaline disagreeable taste, but a strong alkaline reaction to test-paper. When exposed to air, it becomes covered with a pellicle of calcium carbonate; the same compound is formed with the loss of the alkaline reaction if carbonic acid gas is passed through the solution, and the solution heated to expel the excess of the gas. If lime-water is heated to boiling, it becomes turbid from the separation of some calcium hydrate, which dissolves again on cooling. (For the chemical behavior of lime, see Calx, page 325.)

The British Pharmacopœia gives the following test for ascertaining the strength of lime-water: Ten ounces require for neutralization at least 200 grain-measures of the volumetric solution of oxalic acid, which corresponds to 5.6 grains of calcium oxide (CaO).

Pharmaceutical Uses.—In preparing Argenti oxidum, Lotio hydrargyri flava, Lotio hydrargyri nigra, *Br.*, and Linimentum calcis, *U. S.*, *Br.*

Medical Action and Uses.—Lime-water is without caustic qualities, but is astringent and styptic, diminishing more or less the secretion of parts to which it is directly applied, and of the mucous membranes and glands when taken internally. It is a valuable lotion in various diseases of the skin, especially *eczema capitis* and *ulcers.* In the former, the affected part should be thoroughly cleansed with warm water and soap before the lime-water is applied. In all cases of chronic *mucous* or *purulent discharges* from the nostrils, fauces, auditory canals, vagina, urethra, or rectum, it is one of the simplest and best washes. It is said to destroy *ascarides of the rectum.* With flaxseed oil or sweet oil it forms the officinal liniment so useful in the treatment of *burns.*

Internally, as already indicated, it appears to escape the neutralizing influence of the gastric acids, for it has long been used to diminish the mucous secretion in *chronic bronchitis*, and to modify the urine and the lining membrane of the urinary passages in *calculous* and other disorders of urino-genital organs. In vesical diseases lime-water is sometimes injected into the bladder through a catheter, after properly cleansing the organ. It would seem, whether employed in the one or the other manner, to act by diminishing the irritability of the vesical mucous membrane. The constipation that results from the internal use of lime-water, as well as its beneficial operation in chronic bronchitis, prove that it is not fully acidified in the stomach. In *diarrhœa* attended with acid stools and the associated colic and tympanites belonging to acid gastro-intestinal fermentation, and which is so prevalent during hot seasons, especially among infants, lime-water, added to their milk in the proportion of from one-fourth to one-half, is a very efficient remedy. The *aphthous* condition of the mouth and fauces, and the *thrush* that forms there under these circumstances, are often removable by lime-water. In *chronic diarrhœa*, dependent on whatever cause, this solution given with milk as the almost exclusive food, will usually mitigate, and in appropriate cases cure, the disease. The most signal triumphs of this simple method are achieved in *chronic dysentery*, and in cases of *typhoid fever* protracted by the persistence of the intestinal ulcers. Even in tubercular *phthisis* it sometimes suspends the discharges for a considerable time. In all these affections it diminishes *tympanites*, and in certain cases in which that symptom appears to be the result of intestinal fermentation only, lime-water is one of the best remedies. This preparation has been extolled as a remedy for *diabetes*, and the highest testimony in its favor exists, so far as relates to its power of lessening the secretion of sugar. It in like proportion diminishes thirst and voracious appetite. It should be given with milk, or, if that is contra-idicated, with cream, and in quantity not less than one or two pints daily. In *hydruria*, or diabetes insipidus, it is more efficacious still. It has been recommended in *rachitis* and *osteo-malacia;* and is very useful in gouty (acid) *dyspepsia*, especially when taken during the first stages of digestion. The *cutaneous eruptions* so often associated with gouty disorders are usefully treated by the internal use of lime-water.

The demonstration that false membranes are soluble in lime-water led to the use of gargles and the spray of this liquid and the vapors of slaked lime in *pseudo-membranous pharyngitis* (diphtheria), and in *laryngitis* and *bronchitis* of the same type. The result has been the cure of a large number of cases in which the nature of the disease was abundantly demonstrated by inspection, or by the rejection of false membranes. To be successful, the inhalation should be almost uninterrupted. As often as possible the patient should be confined in a dense vapor of slaking lime, and with this the use of atomized lime-water should be alternated, while the room is kept filled with the vapor. Other treatment, except stimulants, is of little use. It may, perhaps, be questioned whether the good results of this method are due to the solvent action of the lime, or to the softening influence of the watery vapor which holds it in solution. Probably both influences contribute to the result.

Lime-water is an appropriate antidote to *arsenious acid*, with which it forms an innocuous compound.

The *dose* of lime-water is from half an ounce to six ounces, given from one to four times a day, with an equal quantity of milk or weak animal broth.

LIQUOR CALCIS CHLORATÆ, *Br.*—SOLUTION OF CHLORINATED LIME.

Chlorure de chaux liquide, Fr.; *Chlorkalk-Flüssigkeit*, G.

Preparation.—Take of Chlorinated Lime one pound; Distilled Water one gallon. Mix well the water and the chlorinated lime by trituration in a large mortar, and, having transferred the mixture to a stopped bottle, let it be well shaken several times for the space of three hours. Pour out now the contents of the bottle on a calico filter, and let the solution which passes through be preserved in a stoppered bottle. *Br.*

The solution has the odor, taste, and general properties of chlorinated lime (see page 326). The British Pharmacopœia requires each fluidounce to contain thirteen grains of available chlorine, which is ascertained by the following test: sixty grains by weight mixed with twenty grains of iodide of potassium dissolved in four fluidounces of water, when acidulated with two fluidrachms of hydrochloric acid, gives a red solution, which requires for the discharge of its color five hundred grain-measures of the volumetric solution of hyposulphite of soda.

Medical Action and Uses.—They are the same as those of chlorinated lime. The solution is convenient as a *deodorizer* of decomposing organic matter, as an *excitant* of the skin in low fevers, and as a stimulant of chronic *cutaneous eruptions.*

LIQUOR CALCIS SACCHARATUS, *Br.*—SACCHARATED SOLUTION OF LIME.

Saccharate (*Sucrate*) *de chaux liquide*, Fr.; *Kalksaccharat-Lösung*, G.

Preparation.—Take of Slaked Lime one ounce; Refined Sugar in powder two ounces; Distilled Water one pint. Mix the lime and the sugar by trituration in a mortar. Transfer the mixture to a bottle containing the water, and having closed this with a cork shake it occasionally for a few hours. Finally separate the clear solution with the siphon, and keep it in a stoppered bottle. *Br.*

Water containing sugar dissolves a larger quantity of lime than pure water. Peligot has ascertained the solubility for 100 parts of sugar in solutions of 40 per cent. to be 26.57 parts; of 20 per cent. only 23.15 parts; and in solutions of 5 per cent. only 18.06 parts of lime. The stronger solution, which has a thin syrupy consistence, has sometimes been used under the name of *Syrupus* *calcis*, *Syrup* or *Saccharate* of lime. Prepared according to the British Pharmacopœia, the solution has the general properties of lime-water, and the specific gravity 1.052. 460.2 grains by weight (1 fluidounce), require for neutralization 254 grain-measures of volumetric solution of oxalic acid, which corresponds to 7.11 grains of lime in one fluidounce.

Medical Action and Uses.—It has been supposed that this solution excelled ordinary lime-water, because it contains more lime. It is probably, however, unsuitable for continued use, since the excess of lime tends to accumulate in the bowels, and irritate and even obstruct them. *Dose*, from fifteen minims to a fluidrachm in water or milk. It has sometimes been employed as an antidote to hydrosulphuric acid and its compounds, in which case it should be freely administered.

LIQUOR CHLORI, *Br.* See AQUA CHLORINII.

LIQUOR EPISPASTICUS, *Br.*—BLISTERING LIQUID.

Linimentum cantharidis, Br., 1864.—*Liqueur vésicant*, Fr.; *Blasenziehende Flüssigkeit*, G.

Preparation.—Take of Cantharides in powder eight ounces; Acetic Acid four fluidounces; Ether a sufficiency. Mix the cantharides and acetic acid; pack them in a percolator, and at the expiration of twenty-four hours pour ether over the contents of the percolator, and allow it to pass slowly through till twenty fluidounces are obtained. Keep it in a stoppered bottle. *Br.*

Cantharidin being soluble both in acetic acid and ether, the preparation should contain the entire amount of that principle in solution. Tichborne preferred to substitute the acetic acid by an equivalent amount of glacial acetic acid, as thereby less water is introduced into the powder. Brady has shown that, when spontaneously evaporated from the skin, the film left is not uniform, but thickest at the circumference. Deane (1876) recommends the discarding of the officinal solvents, and the substitution of acetic ether, which dries more uniformly, and takes up a larger amount of cantharidin.

Medical Action and Uses.—This liquid is intended to produce a rapid vesication, which is effected chiefly by the acetic acid, although the irritation is maintained by the cantharides. It should be well rubbed into the skin with a small mop or piece of sponge attached to a handle, until redness is produced, and should be used only on limited portions of the skin.

LIQUOR FERRI CHLORIDI, *U. S.*—SOLUTION OF CHLORIDE OF IRON.

Liquor ferri perchloridi fortior, Br.; *Liquor ferri sesquichlorati*, P. G.; *Liquor ferri muriatici oxydati*, *Ferrum sesquichloratum solutum.*—*Solution of ferric chloride*, *Strong solution of perchloride of iron*, E.; *Solution de perchlorure de fer*, *Chlorure ferrique liquide*, Fr.; *Flüssiges Eisenchlorid*, G.

The specific gravities of the officinal solutions of ferric chloride are: 1.480 to 1.484 *P. G.*, 1.44 *Br.*, 1.355 *U. S.*, 1.26 *F. P.*

Preparation.—Take of Iron in the form of wire and cut in small pieces three troyounces; Muriatic Acid seventeen troyounces and a half; Nitric Acid, Distilled Water, each a sufficient quantity. Put the iron into a flask measuring two pints, pour upon it eleven troyounces of the muriatic acid, and let the mixture stand until effervescence ceases; then heat to the boiling point, decant the liquid, filter through paper, and, having rinsed the flask with a little distilled water, boiling hot, pour the washings upon the filter. Put the filtered liquid into a porcelain capsule measuring four pints, mix with it the residuary muriatic acid, and, having heated the mixture nearly to the boiling point, add a troyounce and a half of nitric acid. Upon the cessation of effervescence, drop in nitric acid until it no longer occasions effervescence; and, when the liquid becomes cool, add sufficient distilled water to make it measure a pint. *U. S.*

Take of Iron Wire two ounces; Hydrochloric Acid twelve fluidounces; Nitric Acid nine fluidrachms; Distilled Water eight fluidounces. Mix eight fluidounces of the hydrochloric acid with the distilled water, and in this dissolve the iron at a gentle heat. Filter the solution, add to it the remainder of the hydrochloric acid and the nitric acid, heat the mixture briskly until on the sudden evolution of red fumes the liquid becomes of an orange-brown color, then evaporate by the heat of a water-bath until it is reduced to ten fluidounces. *Br.*

The reactions which take place in the preparation of ferric chloride, and the proper manipulations to insure success, have been described. (See Ferri chloridum, page 613.) The solution of the U. S. Pharmacopœia differs from the similar solutions of the other pharmacopœias in containing an excess of one troyounce of muriatic acid to the pint; the difference in density has been stated above.

Properties and Tests.—Solution of ferric chloride is a reddish-brown liquid, which has a strong styptic taste and may be mixed with water and alcohol in all proportions without producing a precipitate. Diluted with water, it is not precipitated by barium chloride or potassium ferridcyanide (absence of sulphate and ferrous salt), but yields a white precipitate with silver nitrate (chloride), and a dark blue precipitate of Prussian blue with potassium ferrocyanide. The absence of nitric acid is proven by adding a crystal of ferrous sulphate to a little of the solution and afterwards a few drops of strong sulphuric acid, when a black color should not be produced near the crystal. Two fluidrachms of the solution, diluted with water and mixed with an excess of ammonia water, yield a reddish-brown precipitate which, when washed and ignited, weighs 28.25 grains U. S. P., 31.24 grains Br. P.

Pharmaceutical Uses.—*Martin's hemostatic*, which is used in France, consists of selected pieces of spunk, which are saturated with ferric chloride.

Adrian's hemostatic is made by dissolving 15 grams of sodium chloride in 60 grams of water, and adding 25 grams of solution of ferric chloride specific gravity 1.26.

FERRUM ALBUMINATUM is a compound of ferric chloride and albumen, which has been recently introduced in Europe, and for which J. Biel (1878) has given the following process: 10 grams of dry soluble egg-albumen are dissolved in 100 grams of distilled water; the clear solution is mixed with 2.4 grams of solution of ferric chloride, *P. G.* (or 1.75 grams of crystallized ferric chloride, see page 613), previously diluted with 24 grams of distilled water; 20 grams of 90 per cent. alcohol are now added, and sufficient water to make 200 grams. This concentrated solution will keep in the dark without alteration; for dispensing, to obtain the *Liquor ferri albuminati*, one part of it is diluted with 4 parts of distilled water, and then contains 0.033 per cent. of metallic iron, the strength generally adopted in Europe. It is more convenient, however, to evaporate the concentrated solution at a temperature not exceeding 40° C. (104° F.), when the compound is obtained in golden-yellow transparent scales containing 3.34 per cent. iron, and yield the solution, by dissolving them in 100 times their weight of distilled water.

Off. Prep.—Liquor ferri perchloridi, *Br.;* Tinct. ferri chloridi (perchloridi), *U. S.*, *Br.*

Medical Action and Uses.—Solution of chloride of iron is used chiefly for the styptic and astringent qualities which it possesses in a high degree.

Its efficiency as an internal medicine is displayed in various *passive hemorrhages*, particularly of the stomach, bowels, uterus, and urinary passages. It is useful in several profluvia, as *leucorrhœa*, *hydruria*, nocturnal *incontinence of urine*, and *vesical catarrh*. It is reported to control *seminal emissions* due to irritability of the urethra or spermatic ducts. In chronic *dysentery* it is one of the best of the astringent medicines appropriate to that affection; it may be prescribed internally and by enema. This preparation is more frequently employed locally as a styptic and astringent in *epistaxis*, hemorrhage from *leech bites*, from the jaw after the *extraction of teeth*, from the *tonsils*, from *cancer of the uterus*, from the *umbilical* cord, from the rectum in *hemorrhoids*, from the uterus after *abortion*, and from *vascular growths* in the cavity of that organ. One of its most valuable applications is to the arrest of *post-partum hemorrhage* caused by uterine inertia. Dr. Barnes, who first employed it, made use of a mixture of half a pint of the stronger solution of the chloride (B. P.) with a pint and a half of water. He directed that a tube about nine inches long should be carried by the hand to the fundus of the uterus previously freed from coagula, and that the liquid should be very slowly injected, care being taken that no air accompanied it. It is stated never to fail, and in no case to do any harm. Numerous confirmatory cases have been published. In *pulmonary hemorrhage* a weak solution of the chloride has been successfully used in the form of atomized spray. It may be employed to check *gastric hemorrhage* in any of the various conditions in which that accident occurs. This powerful styptic has been used to cure *aneurisms*, varicose, sacculated, and others; but although the operation is successful in coagulating the blood in the tumor, it has so often happened either that the tumor suppurated, or that purulent infiltration took place around it, or that fatal embolism occurred, that the operation is no longer considered warrantable. It has been most successful in erectile tumors of the scalp; and safest when the tumors, previously blistered or not, have been covered with compresses wet with the astringent solution. *Varicose veins* have been treated by injections of this preparation, pressure being maintained immediately above the point operated upon. In chronic *ophthalmia* with varicose enlargement of the bloodvessels, it affords, probably, the best chance of cure. As a local application in *diphtheria* it appears to excel all other stimulants and caustics. In the same manner it cures *chilblains*, and is advantageous in *zona*. It is useful in repressing fungous granulations everywhere, but especially in cases of *in-grown toe nail*, and in ulceration of the *gums*. It also forms one of the best dressings for *hospital gangrene*, hardening the tissues and correcting the fetor. In *prolapsus of the rectum* it has been efficiently employed, the projecting bowel being well painted with the solution and then reduced; after which it is retained by means of a tampon moistened with a diluted solution of the medicine. *Dose*, from one to ten minims mixed with syrup, and largely diluted. The teeth should be carefully guarded against its action, by administering the liquid through a glass tube, and by thoroughly washing the mouth after its use.

LIQUOR FERRI PERCHLORIDI, *Br.*—SOLUTION OF PERCHLORIDE OF IRON.

Solution de chlorure ferrique diluée, Fr.; *Verdünnte Eisenchlorid-Lösung*, G.

Preparation.—Take of Strong Solution of Perchloride of Iron five fluidounces; Distilled Water fifteen fluidounces. Mix. *Br.*

This preparation is intended to take the place of the tincture of ferric chloride, as it retains the iron salt in an unchanged condition.

See Liq. ferri chloridi.

LIQUOR FERRI CITRATIS, *U. S.*—SOLUTION OF CITRATE OF IRON.

Liquor ferri citrici, Citras ferricus liquidus.—Citrate de fer liquide, Fr.; *Flüssiges Eisencitrat*, G.

Preparation.—Take of Citric Acid in coarse powder five troyounces and three hundred and sixty grains; Solution of Tersulphate of Iron a pint; Water of Ammonia twenty fluidounces; Distilled Water a sufficient quantity. To the water of ammonia, mixed with two pints of distilled water, add the solution of tersulphate of iron, previously mixed with two pints of distilled water, stirring constantly; transfer the precipitate formed to a muslin strainer, and wash it with water until the washings are nearly tasteless. After the precipitate has been drained, put half of it into a porcelain capsule, on a water-bath heated to 140° F., add the citric acid, and stir the mixture until the precipitate is nearly dissolved. Then add so much of the reserved precipitate as may be necessary fully to saturate the acid. Lastly, filter the liquid, and evaporate it, at a temperature not above 140° F., until it is reduced to the measure of a pint. *U. S.*

The first part of the process consists in preparing ferric hydrate; the reaction has been explained (see page 625). The hydrate retains a considerable quantity of water, so that on the addition of citric acid the mixture becomes liquid as the acid is dissolved and ferric citrate formed. The solution is aided by the application of heat which should never exceed 66° C. (151° F.), but is best kept at 60° C. (140° F.) to prevent decomposition. The digestion must be continued for several hours until the acid has taken up as much iron as can combine with it, when it is filtered and evaporated as directed.

Properties.—The solution has a dark brown color and a slightly ferruginous taste; when evaporated spontaneously or at a moderate heat, in thin layers, it forms transparent, garnet-red scales, which are readily detached from the glass or porcelain plate. A fluidrachm should yield 30 grains of scales.

Pharmaceutical Uses.—In preparing Ferri citras, Ferri et ammonii citras, and Ferri et quiniæ citras, *U. S.*

Medical Uses.—This solution forms a convenient mode of dispensing citrate of iron. *Dose*, ten minims, or about five grains of the salt.

LIQUOR FERRI NITRATIS, *U. S.*—SOLUTION OF NITRATE OF IRON.

Liquor ferri pernitratis, Br.—*Solution of pernitrate of iron*, E.; *Azotate (pernitrate) de fer liquide*, Fr.; *Salpetersaure Eisenoxyd-Lösung*, G.

Preparation.—Take of Iron in the form of wire and cut in pieces two troyounces and a half; Nitric Acid five troyounces; Distilled Water a sufficient quantity. Mix the iron with twelve fluidounces of distilled water in a wide-mouthed bottle, and add to the mixture, in small portions at a time, with frequent agitation, three troyounces of the nitric acid, previously mixed with six fluidounces of distilled water, moderating the reaction by setting the vessel in cold water, in order to prevent the occurrence of red fumes. When the effervescence has nearly ceased, agitate the solution with the undissolved iron until a portion of the liquid, on being filtered, exhibits a pale green color. Then filter the liquid, and, having poured it into a capacious porcelain capsule, heat it to the temperature of 130° F., and add the remainder of the nitric acid. When the effervescence has ceased, continue the heat until no more gas escapes, and then add enough distilled water to make the liquid measure thirty-six fluidounces. *U. S.*

Take of fine Iron Wire free from rust one ounce; Nitric Acid four and a half fluidounces; Distilled Water a sufficiency. Dilute the nitric acid with sixteen ounces of the water, introduce the iron wire into the mixture, and leave them in contact until the metal is dissolved, taking care to moderate the action, should it become too violent, by the addition of a little more distilled water. Filter the solution, and add to it as much distilled water as will make its bulk one pint and a half (30 fluidounces). *Br.*

Both formulas aim at the production of ferric nitrate, $Fe_2 6NO_3$. If the directions of the British Pharmacopœia are followed, the iron is taken up with the evolution of red vapors, the reaction being as follows: Fe_2+8HNO_3 yields $Fe_2 6NO_3+2NO+4H_2O$. Considerable heat is produced, and may rise to such a degree that nitric acid is vaporized; the reaction must therefore be closely watched, and, if it should become too violent, moderated by the addition of some cold water.

This difficulty is sought to be avoided in the process of the United States Pharmacopœia by first forming ferrous nitrate and converting this into the ferric salt. Berzelius observed that, besides ferrous nitrate, ammonium nitrate is also formed, and no gas evolved, if a mixture of iron, water, and nitric acid is kept below the temperature of 50° C. (122° F.), when $2Fe_2+10HNO_3$ yields $4(Fe2NO_3)+NH_4NO_3+3H_2O$. The formation of ammonia is a secondary reaction, and depends upon the action of the nascent hydrogen upon the excess of nitric acid; it is lessened, but not entirely prevented, by a stronger acid and at a higher temperature, and augmented as the temperature and the acid strength are decreased, sometimes to such a degree that ferrous hydrate is separated. It follows from this that the solutions, as obtained by both formulas, are apt to vary in their composition.

Ordway (1865) found that weak solutions of *ferrous nitrate*, which are free from excess of acid, may be concentrated at 60° C. (140° F.), but must then be evaporated at a lower temperature to prevent oxidation. The green crystals obtained in the cold cannot be dried without decomposition. *Ferric nitrate* has been obtained in colorless or purplish crystals, which are cubes when containing $12H_2O$, or prisms with $18H_2O$.

Properties and Tests.—The solution has a reddish-brown, or, if the acid is somewhat in excess, a pale amber color, which becomes darker on heating, and lighter again on cooling. When mixed with a solution of ferrous sulphate, and then with strong sulphuric acid, it assumes a blackish-brown color. Ferridcyanide of potassium, nitrate of silver, and nitrate of barium do not disturb the solution, proving the absence of ferrous salt, chloride, and sulphate. The specific gravity is 1.060 to 1.070, U. S. P.; 1.107, Br. P.

The ferric oxide obtained from a fluidounce of the solution by precipitating with ammonia, washing, and igniting, is required to weigh between 8 and 10 grains, U. S. P.; 20.6 grains, Br. P.

Medical Action and Uses.—This preparation differs in its properties from the other acid compounds of iron. It is much more astringent than the vegetable acid salts or than the iodide of iron, and less harsh than the sulphuric and muriatic acid compounds. It is used chiefly in chronic *diarrhœa* dependent upon debility of the system, or following dysentery, when no febrile complication exists. It is also profitably employed in *leucorrhœa* affecting feeble and lymphatic females, both internally and locally; and in *menorrhagia* occurring under similar conditions. The *dose* is about ten drops, largely diluted. As an injection, from ten to thirty drops in an ounce of water may be employed.

LIQUOR FERRI PERCHLORIDI. See LIQ. FERRI CHLORIDI.

LIQUOR FERRI SUBSULPHATIS, *U. S.*—SOLUTION OF SUBSULPHATE OF IRON.

Solution of persulphate of iron, Monsel's solution, E.; *Liqueur hémostatique de Monsel*, Fr.; *Basisch-schwefelsaure Eisenoxyd-Lösung, Monsel's Eisenlösung*, G.

Preparation.—Take of Sulphate of Iron in coarse powder twelve troyounces; Sulphuric Acid a troyounce and thirty grains; Nitric Acid a troyounce and three hundred grains; Distilled Water a sufficient quantity. Mix the acids with half a pint of distilled water in a capacious porcelain capsule, and, having heated the mixture to the boiling point, add the sulphate of iron, one-fourth at a time, stirring after each addition until effervescence ceases. Then keep the solution in brisk ebullition until nitrous vapors are no longer perceptible, and the color assumes a deep ruby-red tint. Lastly, when the liquid is nearly cold, add enough distilled water to make it measure twelve fluidounces. *U. S.*

This process is a slight modification of that proposed by D. Squibb (1860). On introducing the ferrous sulphate in small portions into the heated acids, a black color is produced from the union of nitric oxide with ferrous sulphate, which disappears with the copious evolution of red nitrous vapors as fast as the sulphate dissolves in the hot liquid. The mixture foams most towards the end of the process, and after the liquid has again subsided a little of it should be tested with nitric acid to insure its complete oxidation. The amount of sulphuric acid used is insufficient for forming the so-called neutral ferric sulphate. A basic or oxysulphate is the result, which has the composition $2Fe_2O.5SO_3 + Aq$, or $5(Fe_2 3SO_4).Fe_2 6HO$. The mineral *copiapite* is a crystallized hydrate of the same combination. Other more basic ferric sulphates are known, some being soluble, others insoluble in water.

Properties and Tests.—Monsel's solution is a deep brown-red liquid, being nearly of a syrupy consistence, and of the spec. grav. 1.552. It has a very astringent, but not caustic taste, and mixes with water and alcohol in all proportions without decomposition. On dropping sulphuric acid into it, the color becomes lighter, and with a larger quantity of the acid, a separation of whitish ferric sulphate takes place. Diluted with distilled water, it yields precipitates with ammonia water and barium nitrate, but none with nitrate of silver; or with ferridcyanide of potassium. When a crystal of ferrous sulphate is added to a little of the solution, and afterwards some strong sulphuric acid, a blackish color is not produced. When evaporated at a moderate heat upon a glass or porcelain plate, it yields transparent, deliquescent scales, and at a somewhat higher temperature is converted into a yellowish powder, which is less deliquescent.

Medical Uses.—This preparation is chiefly used as a local styptic in cases of *hemorrhage* from parts not readily subjected to pressure, as the nasal cavities, the sockets from which teeth have been extracted, the uterus, vagina, rectum, etc. It has the advantage of being less irritating than other acid salts of iron. It is generally applied by means of a wooden or glass brush, or a fragment of compact sponge. Where pressure can also be made, it should not be omitted. An atomized solution of it has been found successful in some cases of *hæmoptysis*. For this purpose from one to ten grains should be dissolved in an ounce of distilled water. Internally it may be prescribed in the *dose* of from five to fifteen grains properly diluted.

LIQUOR FERRI TERSULPHATIS, *U. S.*—SOLUTION OF TERSULPHATE OF IRON.

Liquor ferri persulphatis, Br.; *Liquor ferri sulfurici oxydati*, P. G.—*Solution of persulphate of iron*, E.; *Persulfate de fer liquide*, Fr.; *Flüssiges schwefelsaures Eisenoxyd*, G.

Preparation.—Take of Sulphate of Iron in coarse powder twelve troyounces; Sulphuric Acid two troyounces and sixty grains; Nitric Acid a troyounce and three hundred and sixty grains; Water a sufficient quantity. Mix the acids with half a pint of water in a capacious porcelain capsule, and, having heated the mixture to the boiling point, add the sulphate of iron, one-fourth at a time, stirring after each addition until effervescence ceases. Then continue the heat until the solution acquires a reddish-brown color, and is free from nitrous odor. Lastly, when the liquid is nearly cold, add enough water to make it measure a pint and a half. *U. S.*

Take of Sulphate of Iron eight ounces; Sulphuric Acid, Nitric Acid, of each six fluidrachms; Distilled Water twelve fluidounces, or a sufficiency. Add the sulphuric acid to ten ounces of the water, and dissolve the sulphate of iron in the mixture with the aid of heat. Mix the nitric acid with the remaining two ounces of the water, and add the dilute acid to the solution of sulphate of iron. Concentrate the whole by boiling, until, by the sudden disengagement of ruddy vapors, the liquid ceases to be black, and acquires a red color. A drop of the solution is now to be tested with red prussiate of potash, and if a blue precipitate forms, a few additional drops of nitric acid should be added, and the boiling renewed, in order that the whole of the sulphate may be converted into persulphate of iron. When the solution is cold, make the quantity eleven fluidounces by the addition, if necessary, of distilled water. *Br.*

The reaction which takes place in these processes is precisely the same as in making the subsulphate of iron, the only difference being that the sulphuric acid is used in sufficient quantity to form ferric sulphate, $Fe_2 3SO_4$. The reaction is explained by the equation $6FeSO_4 + 3H_2SO_4 + 2HNO_3 = 3(Fe_2 3SO_4) + 2NO + 4H_2O$.

Properties.—Solution of ferric sulphate is a dark, reddish-brown liquid, having no odor, and a very astringent, and at the same time acid taste. It is miscible in all proportions with alcohol and water without causing decomposition. Its behavior to reagents is the same as that of the subsulphate. It has the spec. grav. 1.320 U. S. P., 1.441 Br. P. One fluidounce of the solution, diluted with water and mixed with an excess of ammonia water, yields a precipitate which, when washed and ignited, weighs 69 grs. U. S. P., 91.5 grs. Br. P.

Pharmaceutical Uses.—In preparing magnetic oxide of iron, and ferric oxide as an antidote to arsenic, or for preparing the various tartrates and citrates containing iron; also in preparing, by double decomposition, ferri ferrocyanidum, ferri pyrophosphas, *U. S.*, and tinct. ferri acetatis, *Br.*, and in forming the double salt ferri et ammonii sulphas, *U. S.*

Medical Uses.—It may be used for the same purposes as the subsulphate, but is not so eligible, because it is more irritant and less astringent.

LIQUOR GUTTA-PERCHÆ, *U. S.*, *Br. Add.*—SOLUTION OF GUTTA-PERCHA.

Liqueur de gutta-percha, Fr.; *Guttapercha-Lösung*, G.

Preparation.—Take of Gutta-percha in thin slices a troyounce and a half; Purified Chloroform seventeen troyounces; Carbonate of Lead in fine powder two troyounces. To twelve troyounces of the chloroform, contained in a bottle, add the gutta-percha, and shake occasionally until it is dissolved. Then add the carbonate of lead, previously mixed with the remainder of the chloroform, and, having several times shaken the whole together, at intervals of half an hour, set the mixture aside, and let it stand for ten days, or until the insoluble matter has subsided, and the solution become limpid, and either colorless or of a pale straw-color. Lastly, decant the liquid, and keep it in a well-stopped bottle. *U. S.*

Take of Gutta-percha in thin slices one ounce; Chloroform eight fluidounces; Carbonate of Lead in fine powder one ounce. Add the gutta-percha to six fluidounces of the chloroform in a stoppered bottle, and shake them together frequently until solution has been effected. Then add the carbonate of lead, previously mixed with the remainder of the chloroform, and, having several times shaken the whole together, set the mixture aside, and let it remain at rest until the insoluble matter has subsided. Lastly, decant the clear liquid, and keep it in a well-stoppered bottle. *Br.*

Crude gutta-percha does not yield a clear solution with chloroform, but on standing the impurities will rise to the surface, more rapidly if, according to Maschke (1857), the solution is agitated with 1 or 1½ per cent. of water. Hodgson (1861) proposed carbonate of lead with the same object in view, the impurities subsiding with the lead compound. Other heavy and insoluble compounds may be used with the same result of rendering the solution clear and almost or entirely colorless.

Off. Prep.—Charta sinapis, *U. S.*, *Br.*

Medical Uses.—The various applications of this solution are enumerated under Gutta-percha. They consist, briefly, in the adhesive and protective qualities of the film formed by the evaporation of the solvent.

LIQUOR HYDRARGYRI NITRATIS, *U. S.*—SOLUTION OF NITRATE OF MERCURY.

Liquor hydrargyri nitratis acidus, Br.; *Liquor hydrargyri nitrici oxydati*, *Hydrargyrum oxydatum nitricum solutum.*—*Acid solution of nitrate of mercury*, *Solution of pernitrate of mercury*, E.; *Deutoazotate* (*Pernitrate*) *de mercure liquide*, Fr.; *Flüssiges salpetersaures Quecksilberoxyd*, G.

Preparation.—Take of Mercury three troyounces; Nitric Acid five troyounces; Distilled Water six fluidrachms. Dissolve the mercury, with the aid of a gentle heat, in the acid previously mixed with the distilled water. When reddish vapors cease to arise, evaporate the liquid to seven troyounces and a half, and keep it in a well-stopped bottle.

Solution of Nitrate of Mercury may also be prepared as follows: Take of Red Oxide of Mercury three troyounces and one hundred and twenty grains; Nitric Acid three troyounces and three hundred grains; Distilled Water six fluidrachms. Mix the acid with the water, dissolve the oxide of mercury in the mixture, and evaporate to seven troyounces and a half. *U. S.*

Take of Mercury four ounces; Nitric Acid five fluidounces; Distilled Water one and a half fluidounce. Mix the nitric acid with water in a flask, and dissolve the mercury in the mixture without the application of heat. Boil gently for fifteen minutes, cool, and preserve the solution in a stoppered bottle. *Br.*

The mercury is dissolved in the first and last processes by the action of nitric acid, with the extrication of red nitrous vapors to form mercuric nitrate; $3Hg_2 + 16HNO_3$ yields $6(Hg2NO_3) + 4NO + 8H_2O$. It is necessary to apply some heat, particularly at the close of the reaction, to convert into mercuric any mercurous salt which may be present. The second United States process yields the same solution more rapidly, and involves simply a combination of the mercuric oxide with nitric acid, water being liberated; $HgO + 2HNO_3$ yields $HgNO_3 + H_2O$.

Properties and Tests.—The solution is colorless, and has a strong acid reaction and a caustic and metallic taste. Its specific gravity is 2.165 U. S. P.; 2.240 Br. P. A crystal of ferrous sulphate dropped into it soon becomes surrounded with a dark-colored liquid (presence of nitrate). Dropped upon copper, a deposit of mercury is at once produced, and if dropped into very dilute muriatic acid, a white precipitate of mercurous chloride is not formed. The absence of mercurous nitrate is also proven by the yellow (not black) precipitate with soda or potassa solution, and by the scarlet red (not yellow or green) precipitate with potassium iodide; this latter precipitate is soluble in an excess of the precipitant.

If the solution is kept over sulphuric acid, until crystals have been separated, the syrupy liquid will have the composition $Hg2NO_3.2H_2O$; and the crystals contain less water, their composition being $2(Hg2NO_3).H_2O$. If the liquid is further concentrated by heat, nitric acid is given off and the solution contains then basic nitrates which are crystallizable, but when largely diluted with water are converted into more basic insoluble white or yellowish compounds.

The German Pharmacopœia recognizes a *Liquor hydrargyri nitrici oxydulati* (*s. Hydrargyrum oxydulatum solutum, s. Liquor Bellostii*), which is made by dissolving, without heat, 100 parts of powdered crystallized mercurous nitrate in 15 parts of nitric acid to which 885 parts of distilled water are gradually added.

Medical Action and Uses.—It is not used internally. Locally its action is powerfully caustic, destroying the life of the tissue to which it is directly applied, and inflaming the surrounding parts. The slough separates as a yellowish scab. When swallowed by mistake it produces the effects of a powerful corrosive poison, including intense pain, vomiting, purging, collapse, and speedy death, after which the fauces have been found vesicated and discolored, and the stomach presenting brown eschars. Applied to an ulcerated surface, even of small extent, it has caused salivation; and a weak solution of it used in the treatment of itch has occasioned fatal poisoning, with symptoms of corrosion and salivation also.

This preparation is employed to stimulate sluggish restorative processes and to remove indurated tissues. It is a valuable application in chronic and indurated *ulcers* of the neck of the uterus, of whatever nature, but most so, of course, in simple ulcers. Tubercles and ulcers of the skin belonging to *lupus* have sometimes been treated advantageously by this caustic, while appropriate internal medicines were also given. It is advised that it should by applied daily. It is an efficient remedy for *acne* by destroying the diseased sebaceous follicles. It has been recommended as the most successful of local applications for all forms of *syphilitic* sores, of the skin, tongue, throat, etc. The strength of the solution employed must vary with the object in view. In lupus and acne the pure liquid must be used, and applied by means of a pointed glass rod or brush, or a wooden splinter, so as accurately to limit the caustic action to the diseased tissue. When ulcers of the throat are to be treated, one or two minims of the acid to an ounce of water may be used as a gargle, or with an atomizer, care being taken not to inhale the spray; or by means of a sponge mop a mixture of a fluidrachm of the solution with an ounce of water may be applied. For cutaneous ulcers a lotion may be made with thirty minims of the solution and an ounce of water.

LIQUOR HYDRARGYRI PERCHLORIDI, *Br.*—SOLUTION OF PERCHLORIDE OF MERCURY.

Liquor hydrargyri bichloridi.—Solution of corrosive sublimate, E.; *Chlorure de mercure et d'ammoniaque liquide*, *Soluté de sel alembroth*, Fr.; *Sublimat-Lösung*, G.

Preparation.—Take of Perchloride of Mercury, Chloride of Ammonium, each ten grains; Distilled Water one pint. Dissolve. *Br.*

This is a colorless solution of the sal alembroth of the alchymists, having the saline and metallic taste of the salts from which it is made. It yields white precipitates with alkalies and their carbonates, and is decomposed by vegetable juices and the medicinal extracts. It contains one-half grain of corrosive sublimate to the (imperial) fluidounce, and is of one-half the strength of the similar solution which was formerly recognized by the Prussian and other European Pharmacopœias.

Medical Action and Uses.—The object of this preparation appears to be to render the solution of corrosive sublimate more perfect than that in water alone. The average *dose* is one fluidrachm, containing one-sixteenth of a grain of corrosive sublimate.

LIQUOR IODINII COMPOSITUS, *U. S.*—COMPOUND SOLUTION OF IODINE.

Liquor iodi, Br.—*Solution of iodine*, E.; *Soluté ioduré de Lugol*, Fr.; *Lugol'sche Jodlösung*, G.

Preparation.—Take of Iodine three hundred and sixty grains; Iodide of Potassium a troyounce and a half; Distilled Water a pint. Dissolve the iodine and iodide of potassium in the distilled water. *U. S.*

Take of Iodine twenty grains; Iodide of Potassium thirty grains; Distilled Water one fluidounce. Dissolve. *Br.*

Solutions of potassium iodide dissolve iodine in different proportions, weak solutions taking up 1 atom of I for each molecule of KI, or 76.5 parts for 100 parts of the salt. The dissolved portion, therefore, has the composition KI_2. The proportion of iodine to potassium iodide in the second formula approaches the composition given; but the formula of the United States Pharmacopœia directs a larger amount of the salt. The iodine strength of both solutions, however, is nearly alike. Viewed as free iodine held in solution by potassium iodide, one part of the former is represented by 23.3 parts (United States Pharmacopœia) and 24.4 parts (British Pharmacopœia) of the solution.

Properties.—The solution is of a dark brown-red color, having the caustic taste of iodine, and imparting to starch paste a dark blue color. When boiled iodine is given off, but the whole of it does not volatilize until the liquid is evaporated to dryness, and the residuary mass heated nearly to redness. When agitated with chloroform, ether, or bisulphide of carbon, the solution is decolorized.

Medical Action and Uses.—This preparation is considerably stronger in the proportion of its active ingredients than the compound *tincture* of iodine, and is thought to be more efficient, although there is no satisfactory evidence in favor of that opinion. Twenty-four drops of it contain about one grain of iodine. The average *dose* is six drops. It should be administered in a large portion of water.

LIQUOR LITHIÆ EFFERVESCENS, *Br.*—EFFERVESCING SOLUTION OF LITHIA.

Aqua lithiæ effervescens.—Lithia water, E.; *Eau de lithine*, Fr.; *Lithionwasser*, G.

Preparation.—Take of Carbonate of Lithia ten grains; Water one pint. Mix in a suitable apparatus, and pass into it as much pure washed carbonic acid gas, obtained by the action of sulphuric acid on chalk, as can be introduced with a pressure of seven atmospheres. Keep the solution in bottles securely closed, to prevent the escape of the compressed gas. *Br.*

This is a solution of lithium carbonate in water rendered more agreeable by the carbonic acid gas. Each fluidounce contains half a grain of the carbonate, the amount of which is best ascertained by evaporating a known measure of it. The residue should answer to the tests for lithium carbonate.

Medical Uses.—This is merely an agreeable form of administration for lithia, and may be given in the *dose* of from four to twelve fluidounces.

LIQUOR MAGNESIÆ CARBONATIS, *Br.*—SOLUTION OF CARBONATE OF MAGNESIA.

Aqua magnesio-effervescens.—Fluid magnesia, E.; *Eau magnésienne, Magnésie liquide*, Fr.; *Kohlensaure Magnesialösung*, G.

Preparation.—Take of Sulphate of Magnesia two ounces; Carbonate of Soda two and a half ounces; Distilled Water a sufficiency. Dissolve the two salts separately, each in half a pint of water. Heat the solution of sulphate of magnesia to the boiling point, then add to it the solution of carbonate of soda, and boil them together until carbonic acid ceases to be evolved. Collect the precipitated carbonate of magnesia on a calico filter, and wash it with distilled water until what passes ceases to give a precipitate with chloride of barium. Mix the washed precipitate with a pint of distilled water, and, putting them into a suitable apparatus, pass into it pure washed carbonic acid gas, obtained by the action of sulphuric acid on chalk. Let the mixture remain in contact with excess of carbonic acid, retained there under pressure for about twenty-four hours; then filter the liquid to remove any undissolved carbonate of magnesia, and again pass carbonic acid gas into the filtered solution. Finally, keep the solution in a bottle securely closed, to prevent the escape of carbonic acid.

The solution contains about thirteen grains of carbonate of magnesia in a fluidounce. *Br.*

The first part of the above process embraces the preparation of magnesium oxycarbonate $(MgCO_3)_3.Mg2HO$, which is the officinal magnesii carbonas. By the subsequent operation this is dissolved in water by the aid of carbonic acid gas in excess, whereby magnesium carbonate, $MgCO_3$, and bicarbonate, MgH_22CO_3, are formed.

Properties and Tests.—It is a colorless solution, which should effervesce on opening the vessel, carbonic acid escaping, and has a slightly acidulous taste, free from bitterness. The residue left by evaporating a fluidounce and calcining the residue should weigh five grains, and answer to the tests for magnesia. When the solution is exposed to cold, prismatic crystals of magnesium carbonate, $MgCO_3.5H_2O$, appear, which on exposure to the air lose water and become $MgCO_3.3H_2O$.

Medical Uses.—The intention of this preparation is apparently to provide an agreeable form for administering magnesia in cases of constitutional *gout* and other disorders attended with an excess of *acid* in the system, and acid urinary deposits. An extemporaneous mixture of magnesia with carbonated water answers the same purpose, and so do the granular effervescing vegetable salts of magnesia. The *dose* of this preparation is one or two fluidounces.

LIQUOR MAGNESII CITRATIS, *U. S.*—Solution of Citrate of Magnesium.

Liquor magnesiæ citratis, Br. Add.; *Liquor magnesii citrici.—Limonade au citrate de magnésie, Limonade purgative citro-magnésienne*, Fr.; *Flüssige Citronsaure Magnesia*, G.

Preparation.—Take of Carbonate of Magnesium two hundred grains; Citric Acid four hundred grains; Syrup of Citric Acid two fluidounces; Bicarbonate of Potassium forty grains; Water a sufficient quantity. Dissolve the citric acid in four fluidounces of water, and, having added the carbonate of magnesium, stir until it is dissolved. Filter the solution into a strong twelve-ounce bottle, containing the syrup of citric acid. Then add the bicarbonate of potassium and enough water to nearly fill the bottle, which must be closed with a cork secured with twine. Lastly, shake the mixture occasionally until the bicarbonate is dissolved. *U. S.*

Take of Carbonate of Magnesia one hundred grains; Citric Acid two hundred grains; Syrup of Lemons half a fluidounce; Bicarbonate of Potash in crystals forty grains; Water a sufficiency. Dissolve the citric acid in two ounces of the water, and, having added the carbonate of magnesia, stir until it is dissolved. Filter the solution into a strong half-pint bottle, add the syrup and sufficient water to nearly fill the bottle; then introduce the bicarbonate of potash, and immediately close the bottle with the cork, which should be secured with string or wire. Afterwards shake the bottle until the bicarbonate of potash has dissolved. *Br.*

When magnesium carbonate and citric acid are brought together in the presence of water, carbonic acid gas is given off and magnesium citrate formed. The neutral salt has the composition $Mg_32C_6H_5O_7$, is but slightly soluble in water, and crystallizes from its solutions with $14H_2O$. The salt $MgHC_6H_5O_7$ is much more soluble in water, and it is this compound at which both Pharmacopœias aim in the above formulas. The reaction occurs as follows: $(MgCO_3)_3.Mg2HO+4H_3C_6H_5O_7$ yields $4MgHC_6H_5O_7+3CO_2+5H_2O$. A slight excess of citric acid is employed, which is subsequently neutralized with potassium bicarbonate, whereby some potassium citrate is formed and carbonic acid gas liberated, the latter remaining with the hermetically corked solution. Carbonate of magnesium, as ordinarily met with, varies much less in composition than calcined magnesia after some exposure to the atmosphere; the former compound is, therefore, very properly used in preference to the latter.

To prepare the solution, ten times, or any other convenient multiple of the officinal quantities of citric acid and magnesium carbonate are weighed out, mixed with the corresponding quantity of water; after the magnesia has dissolved, the liquid is passed through a paper filter, equally divided among the requisite number of bottles, into each of which the necessary measure of syrup is introduced; sufficient water, previously boiled and filtered, is then added to each bottle, after which the potassium bicarbonate in crystals is dropped in. The corks are then inserted, and securely fastened by twine, and the bottles laid upon their sides in a cool place. Prepared in this way, the crystals will gradually dissolve in the syrup, and this will slowly mix with the lighter saline solution, unless it be wanted for immediate use, when, by slight agitation, the syrup and bicarbonate are dissolved in the aqueous liquid.

The solution is colorless, free from sediment, and of a pleasant acidulous taste free from bitterness.

Medical Action and Uses.—This medicine has come into popular use as a purgative, and, if its constitution could be depended upon, would answer a useful purpose. But as it sometimes purges violently, and in other cases fails of any purgative effect, it ought not to be employed where certainty and uniformity of action are important. It should generally be given in divided doses of four or six ounces every hour until the desired operation is produced.

LIQUOR MORPHIÆ ACETATIS, *Br.*—SOLUTION OF ACETATE OF MORPHIA.

Soluté d'acétate de morphine, Fr.; *Essigsaure Morphinlösung*, G.

Preparation.—Take of Acetate of Morphia four grains; Diluted Acetic Acid eight minims; Rectified Spirit two fluidrachms; Distilled Water six fluidrachms. Mix the acid, the spirit, and the water, and dissolve the acetate of morphia in the mixture. *Br.*

Medical Uses.—Each fluidrachm contains half a grain of morphia acetate, the decomposition of which is prevented by the spirit.

LIQUOR MORPHIÆ HYDROCHLORATIS, *Br.*—SOLUTION OF HYDROCHLORATE OF MORPHIA.

Soluté de hydrochlorate de morphine, Fr.; *Salzsaure Morphinlösung*, G.

Preparation.—Take of Hydrochlorate of Morphia four grains; Diluted Hydrochloric Acid eight minims; Rectified Spirit two fluidrachms; Distilled Water six fluidrachms. Mix the hydrochloric acid, the spirit, and the water, and dissolve the hydrochlorate of morphia in the mixture. *Br.*

Medical Uses.—Each fluidrachm of this solution contains half a grain of muriate of morphia, and its *dose* is from ten to sixty minims. It will be observed that it contains four grains of the morphia salt to the ounce of water, while the solution of sulphate of morphia, U. S. P., contains but one grain to the fluidounce. Trousseau recommends, for hypodermic injection, a solution of muriate of morphia in glycerin, which preserves the salt from decomposition.

LIQUOR MORPHIÆ SULPHATIS, *U. S.*—SOLUTION OF SULPHATE OF MORPHIA.

Soluté de sulfate de morphine, Fr.; *Schwefelsaure Morphinlösung*, G.

Preparation.—Take of Sulphate of Morphia eight grains; Distilled Water half a pint. Dissolve the sulphate of morphia in the distilled water. *U. S.*

In some parts of the United States a much stronger solution is frequently prescribed under the name of *Magendie's solution of morphia*. It is prepared by dissolving 16 grains of sulphate of morphia in one fluidounce of water, and is, therefore, *sixteen times stronger* than that admitted into the Pharmacopœia. *Magendie's solution* is prepared in France by dissolving 0.8 gram ($12\frac{1}{4}$ grains) of morphia acetate in 30 grams (1 fluidounce) of water, and is, therefore, considerably weaker than the solution known by the same name in the United States.

Medical Action and Uses.—This solution, which in a fluidrachm contains one-eighth of a grain of the sulphate, is a convenient form for the administration of morphia. The commencing *dose* for an adult should not generally exceed a fluidrachm. For hypodermic injection it is too weak, and for that purpose a "Magendie's solution" which contains one-fifth of a grain of sulphate of morphia in six minims of the solution is generally employed.

LIQUOR PLUMBI SUBACETATIS, *U. S.*, *Br.*—SOLUTION OF SUBACETATE OF LEAD.

Liquor plumbi subacetici, P. G.; *Acetum plumbicum*, *Acetum saturni*, *Plumbum hydrico-aceticum solutum*, *Subacetas plumbicus liquidus.*—*Goulard's extract*, E.; *Sous-acétate de plomb liquide*, *Extrait de Goulard*, *Vinaigre de plomb* (*de saturne*), F.; *Bleissig*, G.

Specific gravities of the officinal solution: 1.32 F. P., 1.267 U. S., 1.26 Br., 1.235 to 1.240 P. G.

Preparation.—Take of Acetate of Lead sixteen troyounces; Oxide of Lead in fine powder nine troyounces and a half; Boiling Water a sufficient quantity. Put the acetate and oxide into four pints of boiling water, in a glass or porcelain vessel, and boil for half an hour, occasionally adding boiling water to preserve the measure; then filter through paper. Lastly, keep the liquid in a well-stopped bottle. *U. S.*

Take of Acetate of Lead five ounces; Oxide of Lead in powder 3½ ounces; Distilled Water one pint, or a sufficiency. Boil the acetate of lead and the oxide of lead in the water for half an hour, constantly stirring; then filter, and when the liquid is cold, add to it more distilled water, until the product measures twenty fluidounces. Keep the clear solution in stoppered bottles. *Br.*

Several basic acetates of lead are known, both soluble and insoluble in water, which may be obtained by treating solutions of the neutral acetate with the requisite quantity of oxide of lead. The exact composition of the officinal solutions depends, therefore, upon the proportion of the two compounds. The U. S. Pharmacopœia has adopted the views of Döbereiner, Berzelius, and others, in using the compounds in very nearly the proportion of their molecular weights, while the British Pharmacopœia orders an excess of oxide. In both cases a large amount of white insoluble residue is left, consisting of the oxyacetate $Pb2C_2H_3O_2.5(Pb2HO)$; both solutions contain chiefly the diplumbic acetate $Pb2C_2H_3O_2.Pb2HO$, that of the British Pharmacopœia also some $Pb2C_2H_3O_2.2(Pb2HO)$. The German and French Pharmacopœias use the two ingredients in the proportion of 3 parts of acetate to 1 of oxide, which results in the production of another basic salt having the composition $2(Pb2C_2H_3O_2).Pb2HO$.

The combination of the chemicals may be effected at the ordinary temperature by macerating the finely levigated litharge with the solution of lead acetate, in a corked bottle, and agitating occasionally until the sediment has become white; from two to four days are usually required. By boiling all the ingredients as directed in the formulas above, precisely the same result is obtained in a much shorter time, and the process is preferable to that of the German Pharmacopœia, which directs the heating of the mixed acetate and oxide by means of a steam-bath, until they fuse into a white mass, which is then to be treated with warm water.

Properties and Tests.—Solution of subacetate of lead is a colorless liquid, having a sweet, astringent taste, and an alkaline reaction to test-paper; the specific gravity has been given above. Added to a solution of gum-arabic, a dense white precipitate is produced; otherwise it has the reactions of lead and acetic acid. When completely precipitated by an excess of sulphuric acid, the filtrate, on being evaporated to dryness, leaves no residue, or only a very slight one (absence of other salts). When precipitated by an excess of ammonia, the filtrate should not have a blue color (absence of copper). The British Pharmacopœia requires that 413.3 grains of the solution should be precipitated by not less than 810 grain-measures of the volumetric solution of oxalic acid. On exposure to air, or on being mixed with water containing air in solution, the solution yields a white precipitate of carbonate of lead. It unites readily with liquid and solid fats.

Off. Prep.—Cerat. plumbi subacet. (Ung. plumbi subacet. comp.), *U. S.*, *Br.;* Linimentum plumbi subacet., *U. S.;* Liquor plumbi subacet. dilutus, *U. S.*, *Br.*

Medical Action and Uses.—This solution has occasioned violent toxical symptoms when taken internally, which it never should be for medicinal purposes. It is employed whenever an astringent and local sedative action is required to allay pain or inflammation, to constringe flaccid tissues, or to lessen secretion. Whenever applied to the denuded cutis, its use should not be continued long, lest acute poisonous effects be developed. It is of common use, diluted, in the treatment of *contusions*, *sprains*, *excoriations*, *fractures*, *burns*, *wounds*, *abscesses*, *hernia*, *hemorrhoids*, and various cutaneous *eruptions* of an inflammatory sort. It is best applied on soft cloths, lint, etc., and should be covered with water-proof tissue. Spongio-piline is a convenient vehicle for its use. The mucilage of slippery-elm or of quince seeds causes a precipitation of the lead from this solution; flaxseed and sassafras pith mucilage are less objectionable. For practical use the diluted solution is in most cases preferable.

LIQUOR PLUMBI SUBACETATIS DILUTUS, *U. S.*, *Br.*—DILUTED SOLUTION OF SUBACETATE OF LEAD.

Aqua plumbi, P. G.; *Aqua plumbica (vel saturnina).*—*Lead water*, E.; *Eau de saturne*, *Eau blanche*, Fr.; *Bleiwasser*, *Kühlwasser*, G.

Preparation.—Take of Solution of Subacetate of Lead three fluidrachms; Distilled Water a pint. Mix them. *U. S.*

Take of Solution of Subacetate of Lead, Rectified Spirit, each two fluidrachms; Distilled Water nineteen and a half fluidounces. Mix, and filter through paper. Keep the clear solution in a stoppered bottle. *Br.*

The use of distilled water does not prevent the mixture from becoming turbid at once, the carbonic acid held in solution or contained in the atmosphere producing some carbonate of lead. Other Pharmacopœias use common water, and several of them give, in addition to the above, another formula for *Goulard's lead water*, *Aqua plumbi Goulardi*, P. G.; *Aqua vegeto-mineralis Goulardi vel Lotio plumbea*, *Eau de Goulard*, Fr.; *Goulardsches Wasser*, G.; which is prepared by mixing 90 parts of common water, 2 parts of solution of subacetate of lead, and 8 parts of alcohol (specific gravity .892) or of vulnerary tincture.

Medical Uses.—It is this rather than the stronger solution of subacetate of lead that is commonly employed for the various purposes above indicated. When it is used as a lotion merely, and is not confined by dressings, it is rendered more efficient by the addition of alcohol, in the proportion of three or four drachms to a pint of the solution.

LIQUOR POTASSÆ, *U. S.*, *Br.*—SOLUTION OF POTASSA.

Liquor kali caustici, P. G.; *Kali hydricum solutum*, *Lixivium causticum.* —*Solution of potash*, E.; *Potasse caustique liquide*, *Lessive caustique*, Fr.; *Aetzkalilauge*, *Kalilauge*, G.

Specific gravity of the officinal solutions: 1.065, U. S.; 1.058, Br.; 1.330 to 1.334, P. G., F. P.

A solution of HKO in water.

Preparation.—Take of Bicarbonate of Potassium fifteen troyounces; Lime nine troyounces; Distilled Water a sufficient quantity. Dissolve the bicarbonate of potassium in four pints of distilled water, and heat the solution to the boiling point. Mix the lime with four pints of distilled water, and, having heated the mixture to the boiling point, add it to the alkaline solution, and boil for ten minutes. Then transfer the whole to a muslin strainer, and, when the liquid portion has passed, add enough distilled water through the strainer to make the strained liquid measure seven pints. Lastly, keep the liquid in well-stopped bottles of green glass.

Solution of potassa thus prepared has the specific gravity 1.065, and contains five and eight-tenths per cent. of hydrate of potassium.

Solution of potassa may also be prepared in the following manner:—

Take of Potassa a troyounce; Distilled Water a pint. Dissolve the potassa in the distilled water, and allow the solution to stand until the sediment subsides. Then pour off the clear liquid, and keep it in a well-stopped bottle of green glass. *U. S.*

Take of Carbonate of Potash one pound; Slaked Lime twelve ounces; Distilled Water one gallon. Dissolve the carbonate of potash in the water, and, having heated the solution to the boiling point in a clean iron vessel, gradually mix with it the slaked lime, and continue the ebullition for ten minutes with constant stirring. Then remove the vessel from the fire, and, when by the subsidence of the insoluble matter the supernatant liquor has become perfectly clear, transfer it by means of a siphon to a green glass bottle furnished with an air-tight stopper, and add distilled water if necessary to make it correspond with the tests of specific gravity and neutralizing power. *Br.*

On bringing together potassium carbonate and slaked lime in the presence of water a double decomposition is effected, resulting in the formation of potassium hydrate and calcium carbonate; $K_2CO_3 + CaH_2O_2$ yields $2KHO + CaCO_3$. This reaction cannot be completed in concentrated solutions, but occurs promptly in dilute solutions. The smallest quantity necessary for 1 part of potassium carbonate, according to Watson, is 8 parts of water; Mohr, however, prefers to use not less than 12 parts, and to concentrate the caustic liquor if necessary with sufficient water. The decomposition may be effected in the cold by frequent agitation, but the resulting calcium carbonate is then light and retains much of the liquor, while at the same time silica, if present in the carbonate, is not completely removed. The British Pharmacopœia uses potassium carbonate and water in the proportion of 1 to 10; the United States Pharmacopœia nearly in the proportion of 1 to 11, having substituted the much purer bicarbonate for the carbonate. Should the materials be chemically pure, one part of slaked lime would be sufficient to decompose a fraction over two parts of potassium carbonate, and nearly the same proportion would be required for burned lime and potassium bicarbonate if in boiling the solution of the latter carbonic acid was not given off. It will thus be seen that both Pharmacopœias direct the employment of an unnecessarily large quantity of lime. This excess may be avoided by following the directions of the British Pharmacopœia, to add the milk of lime gradually in small portions to the boiling alkaline liquid; when this addition amounts to a quantity of lime equal to about one-half the weight of the potassium salt, a small portion of the boiling mixture is poured upon a small moistened filter, and the filtrate collected in a test-tube containing a little hydrochloric acid. Should effervescence occur, the boiling must be continued, and more lime added, until on testing as before, a new filter being used each time, no effervescence is observed. The removal of the caustic liquor may be effected either by filtering it at once through muslin, or, better still, we think, by allowing the insoluble matter to subside, drawing off the clear liquor by means of a siphon, and transferring the sediment before it has become hard upon a muslin strainer, and washing the potassa out by means of distilled water. In all cases the liquid should be brought to the proper density by the addition of water, or, if necessary, by evaporation. A well-cleaned iron vessel is best adapted for the above operation.

Other methods for obtaining potassa solution adapted for special purposes have been recommended. Schubert decomposed potassium sulphate accurately by a hot solution of baryta. Hunter (1866) arrived at the same result by substituting lime for the baryta, and by boiling and filtering under a pressure of about 40 pounds to the square inch. F. Schulze (1861) heated a mixture of 1 part of pure potassium nitrate with 3 parts of ferrous oxalate to dull redness while hydrogen gas was being conducted to the bottom of the crucible. Wöhler's process (1853), to heat a mixture of 1 part of potassium nitrate and 2 of copper to dull redness, is apt to yield a product containing potassium nitrite if the mixture has not been intimate, or if the heat is not continued long enough; Polacci (1872) found the solution in water to contain a little copper.

Properties.—Potassa solution is a clear and colorless liquid of the specific gravity stated above, and has a strong alkaline reaction and a very caustic taste. The slight peculiar odor which it usually has is due to its action upon organic bodies which may have been derived from the atmosphere. It dissolves wool, skin, and other animal and many vegetable substances, and decomposes fats, forming therewith soluble soaps. It attracts carbonic acid from the air with great avidity, and must therefore be preserved in well-stopped bottles. Green glass, free from lead, is best adapted for the purpose, but is likewise somewhat decomposed by alkalies, which cause the stopper to become firmly fastened into the bottle, unless protected by a thin layer of paraffin. Potassa solution decomposes the salts of ammonium, of the metals, and of all the alkaloids, and induces the decomposition of tannin and its derivatives.

Tests.—The solution should not effervesce, or but slightly so, when added to an excess of dilute muriatic acid. When acidulated with nitric acid, it may give a slight turbidity with barium nitrate (*sulphate*), silver nitrate (*chloride*), or sodium carbonate (*alumina*); and when the acidulated solution is evaporated to dryness the residue should form a clear or merely a slightly turbid (from presence of *silica*) solution in water, which should not be disturbed by ammonia and magnesium chloride (absence of phosphate). It is not precipitated or colored black by hydrogen sulphide, either before or after being acidulated (absence of *metals*). It differs from soda solution in yielding a white crystalline precipitate with an excess of concentrated solution of tartaric acid, and a yellow one on the addition of hydrochloric acid and platinic chloride. The British Pharmacopœia demands that 462.9 grains (1 fluidounce imperial) should require for neutralization 482 grain-measures of the volumetric solution of oxalic acid, which corresponds to 5.84 per cent. by weight of potassium hydrate, or 27 grains in one fluidounce. The solution of the United States Pharmacopœia is likewise stated to contain 5.8 per cent. of the hydrate; but the solution is denser than that of the British. The following table, computed by Gerlach (1869), gives the specific gravity of potassa solution at 15° C. (59° F.), containing from 1 to 60 per cent. of potassium oxide, and the same percentages of potassium hydrate:—

Per-centage.	K_2O	KHO	Per-centage.	K_2O	KHO	Per-centage.	K_2O	KHO
1	1.010	1.009	21	1.230	1.188	41	1.522	1.425
2	1.020	1.017	22	1.242	1.198	42	1.539	1.438
3	1.030	1.025	23	1.256	1.209	43	1.554	1.450
4	1.039	1.033	24	1.270	1.220	44	1.570	1.462
5	1.048	1.041	25	1.285	1.230	45	1.584	1.474
6	1.058	1.049	26	1.300	1.241	46	1.600	1.488
7	1.068	1.058	27	1.312	1.252	47	1.615	1.499
8	1.078	1.065	28	1.326	1.264	48	1.630	1.511
9	1.089	1.074	29	1.340	1.276	49	1.645	1.527
10	1.099	1.083	30	1.355	1.288	50	1.660	1.539
11	1.110	1.092	31	1.370	1.300	51	1.676	1.552
12	1.121	1.101	32	1.385	1.311	52	1.690	1.565
13	1.132	1.111	33	1.402	1.324	53	1.705	1.578
14	1.143	1.119	34	1.418	1.336	54	1.720	1.590
15	1.154	1.128	35	1.431	1.349	55	1.733	1.604
16	1.166	1.137	36	1.445	1.361	56	1.746	1.618
17	1.178	1.146	37	1.460	1.374	57	1.762	1.630
18	1.190	1.155	38	1.475	1.387	58	1.780	1.641
19	1.202	1.166	39	1.490	1.400	59	1.795	1.655
20	1.215	1.177	40	1.504	1.411	60	1.810	1.667

Pharmaceutical Uses.—By evaporating the solution it yields Potassa (Potassa caustica), *U. S.*, *Br.* It is employed in the officinal processes for the following: Antim. sulphurat., Argenti oxidum, Atropia, Hydrarg. oxidi flavum, *U. S.;* Potassii bromidum, Potassii iodidum, *Br.*

Physiological Action.—Solution of potassa possesses in a degree the caustic properties of the pure alkali, since it contains nearly six per cent. of the latter. The soapy feel which it gives to the fingers is due to its combination with the unctuous secretion of the skin. In medicinal doses, and taken during or after a meal, it speedily combines with the acids then abundantly secreted by the stomach; but, if properly diluted, and used when the stomach is empty, it is absorbed and tends to neutralize the acid secretions, especially the urine along with which it is chiefly eliminated. Used habitually, it lessens the coagulability of the blood and dissolves out the hematin from the red corpuscles, giving rise to paleness and puffiness of the skin, passive hemorrhages, general emaciation, and, in a word, to the ordinary phenomena of scurvy. This aplastic operation explains its efficacy in moderating a tendency to plastic exudations, in promoting the absorption of those already existing, and in modifying nutrition generally.

Medical Uses.—Solution of potassa limits or suspends the formation of *acid urinary deposits* and *concretions*, by neutralizing the free acids with which they are formed, while it spares the urinary passages from the irritation of their contact. But, since these acids always proceed from some defect of primary assimilation, the mere neutralization of them when formed does not necessarily effect a radical cure, which must be sought in the use of remedies tending to bring the digestive powers and the work of digestion into due proportion and harmony. For this purpose, dietetic and hygienic measures are the most efficient. The *gastric symptoms*, which call for solution of potassa and other antacid medicines, are heartburn, sour eructations, aphthæ, œsophageal spasm, vomiting, cramp in the stomach, colic, and irregular diarrhœa. It is probable that such medicines, by correcting acidity, tend to promote the due digestion of food, and thereby indirectly to remove the debility of the system upon which *acid dyspepsia* depends. Certain it is that in cases of "uric acid diathesis," as it has been called, the alkaline treatment duly carried out will sometimes suspend the faulty secretion for an indefinite period. It is true that this result is more usual after the liberal use of diuretic mineral waters, which probably cleanse the urinary channels of accumulated deposits, than by the use of solution of potassa, or of any other alkali alone. The *tympanites* incident to this form of dyspepsia is best palliated by the medicine when it is given in a bitter infusion. *Strangury* from cantharides is said to be both prevented and relieved by twenty minims of solution of potassa largely diluted. In *acne* of the face (gutta rosacea) the internal use of the medicine is sometimes very efficient, and it has been equally recommended for the prevention and cure of *boils* in cases where they occur in successive crops. *Scrofulous glandular swellings* are doubtless diminished during a course of this medicine, but its debilitating effects upon the system should at the same time be counteracted by appropriate food and cod-liver oil. It is injurious in *phthisis*, but, on the other hand, useful in *chronic bronchitis*, especially when associated with emphysema, and when expectoration is difficult and the sputa are scanty and tenacious. The mode of action implied in some of the preceding statements receives a further support by solution of potassa having been used successfully to moderate *obesity*. The hypothesis invoked to explain its action is that "it increases the vital powers of metamorphosis, by saponifying in part the fat contained in the blood and enabling it to be burnt off as carbonic acid." We should incline to the opinion that it acts by slowly poisoning the victim, radically disorganizing his blood, and hindering his nutrition. For the purpose intended it has been given in the dose of one or two fluidrachms three times a day, a dose which probably no stomach could long receive with impunity. Experiments and observations in India furnish some reason for thinking that solution of potassa is an antidote to *serpents' bites*. They are not, however, conclusive. The power of this solution to dissolve organic products has been used to soften the nail in cases of *ingrown nail*, and gradually to permit its removal, leaving the fungous granulations free from its irritation. It has been recommended to add solution of potassa to the lime-water used for atomized inhalation in *diphtheritic* affections of the throat and larynx, in the proportion of about ten or fifteen drops to five or six ounces of lime-water diluted one-half with pure water.

Solution of potassa may be administered internally in the *dose* of from ten minims to a fluidrachm largely diluted by a mucilaginous or sweetened aromatic infusion. It should not be prescribed along with henbane, belladonna, or stramonium, whose medicinal properties it destroys.

LIQUOR POTASSÆ EFFERVESCENS, *Br.*—
EFFERVESCING SOLUTION OF POTASH.

Aqua potassæ effervescens.—*Potash water*, E.; *Eau alcaline gazeuse*, Fr.; *Alkalisches Mineralwasser*, G.

Preparation.—Take of Bicarbonate of Potash thirty grains; Water one pint (imperial). Dissolve the bicarbonate of potash in the water and filter the solution; then pass into it as much pure washed carbonic acid gas, obtained by the action of sulphuric acid on chalk, as can be introduced with a pressure of seven atmospheres. Keep the solution in bottles securely closed, to prevent the escape of the compressed gas. *Br.*

Properties and Tests.—The solution effervesces strongly when the containing vessel is opened, carbonic acid gas escaping; it is clear and sparkling, and has an agreeable acidulous taste. Ten fluidounces, after being boiled for five minutes, require for neutralization 150 grain-measures of the volumetric solution of oxalic acid. Five fluidounces, evaporated to one-fifth, and 12 grains of tartaric acid added, yield a crystalline precipitate, which, when dried, weighs not less than 12 grains.

Medical Uses.—The remarks made under Liquor magnesiæ carbonatis are quite as applicable to this preparation. Solution of potassa is usually given in a bitter infusion; but if, for any reason, that vehicle is objectionable, it can very well be administered in carbonic acid water. The cases are, however, rare in which potassa is preferable to the bicarbonate of sodium.

LIQUOR POTASSII ARSENITIS, *U. S.*—SOLUTION OF ARSENITE OF POTASSIUM.

Liquor arsenicalis, Br.; *Liquor kali arsenicosi*, P. G.; *Solutio arsenicalis Fowleri, kali arsenicosum solutum.—Arsenical solution, Fowler's solution*, E.; *Liqueur (solution) arsenicale de Fowler*, Fr.; *Fowler'sche Tropfen*, G.

The officinal solutions contain 1 part of arsenious acid in 90 parts, P. G.; 100, F. P.; 111, Br. P.; 116, U. S. P., parts by weight.

Preparation.—Take of Arsenious Acid in small pieces, Bicarbonate of Potassium, each sixty-four grains; Compound Spirit of Lavender half a fluidounce; Distilled Water a sufficient quantity. Boil the arsenious acid and bicarbonate of potassium in a glass vessel, with half a fluidounce of distilled water, until the acid is entirely dissolved, and add twelve fluidounces of distilled water. Then add the compound spirit of lavender, and afterwards enough distilled water to make it measure a pint. *U. S.*

Take of Arsenious Acid in powder, Carbonate of Potash, each eighty grains; Compound Tincture of Lavender five fluidrachms; Distilled Water a sufficiency. Place the arsenious acid and the carbonate of potash in a flask with ten ounces of the water, and apply heat until a clear solution is obtained. Allow this to cool. Then add the compound tincture of lavender, and as much distilled water as will make the bulk one pint (imperial). *Br.*

The United States Pharmacopœia very properly directs the mixture of potassium salt and arsenious acid to be boiled in a small quantity of water, whereby a combination and solution is readily effected, the liquid containing potassium arsenite, which is probably HK_2AsO_3. When this is subsequently diluted with water and remains in contact with the air, it absorbs carbonic acid again, and the solution will then be identical with that of the British Pharmacopœia, which must be regarded merely as a solution of arsenious acid in the alkaline carbonate, from which a portion crystallizes again when the solution is long kept. On keeping 100 grams for three years, Ménière (1876) collected 0.15 gram, or 15 per cent. of the amount originally dissolved. The precise circumstances under which this separation takes place have not been ascertained; but the separation is undoubtedly due to the gradual conversion of the arsenious acid into the crystalline modification, which is but sparingly soluble. It is evident, however, that Fowler's solution cannot be kept unchanged for an indefinite period, and it is advisable that it be prepared in no larger quantities than will be sufficient for a few months or a year.

Properties and Tests.—Fowler's solution is a reddish liquid, at first somewhat opalescent, having an alkaline reaction to test-paper, and the odor of lavender. Its specific gravity is 1.009. It gives the usual reactions of arsenic, and requires to be acidulated with muriatic acid before it will be precipitated by hydrogen sulphide. The amount of arsenious acid contained in it is conveniently ascertained with iodine, with starch paste as an indicator, which is not permanently colored blue until the arsenious has all been oxidized to arsenic acid, hydriodic acid being formed at the same time; $As_2O_3 + 5H_2O + 2I_2$ yields $2H_3AsO_4 + 4HI$. The British Pharmacopœia gives the following test: a fluidounce (441.5 grains) of the solution is boiled for five minutes with ten grains of sodium bicarbonate, and then diluted with six fluidounces of distilled water containing a little starch paste; 808 grain-measures of the volumetric solution of iodine should be necessary for the reaction, and will indicate 4 grains of arsenious acid.

Medical Uses.—The action and uses of this medicine have been sufficiently discussed elsewhere (see Acidum arseniosum). It is sufficient in this place to state that its efficacy is most conspicuous in *squamous diseases of the skin*, *intermittent fever*, *neuralgia*, especially of the trifacial, and in *nervous asthma*. The commencing *dose* should not exceed five drops, nor should it be given when the stomach is empty, nor unless greatly diluted.

LIQUOR POTASSII CITRATIS, *U. S.*—SOLUTION OF CITRATE OF POTASSIUM.

Liquor kali citrici.—*Citrate de potasse liquide*, Fr.; *Flüssiges Citronensaures Kali*, G.

Preparation.—Take of Citric Acid half a troyounce; Bicarbonate of Potassium three hundred and thirty grains; Water half a pint. Dissolve the acid and bicarbonate in the water, and strain the solution through muslin. *U. S.*

This is a solution of potassium citrate containing a little free carbonic acid, and differs from mistura potassii citratis in the absence of the yellowish color and the agreeable lemon flavor. Instead of straining the finished solution to remove particles of foreign matter, it is preferable to dissolve the chemicals separately in one-half the water, strain or filter if necessary, and mix the clear solutions; a larger quantity of carbonic acid gas will thus be retained in the liquid.

Medical Action and Uses.—This preparation is nearly identical in its action with Mistura potassii citratis, *U. S. P.*, and Liq. potassii effervescens, *Br. Ph.*, and with the effervescing draught prepared extemporaneously. When the intention is solely to affect the system after absorption of the salt, either of the first two will lessen the tension of the arterial system, and promote *diaphoresis*; but when it is intended at the same time to make an impression upon the stomach itself, the carbonic acid extricated during effervescence becomes an important part of the dose. The primary action of the gas is to stimulate organically, while it perhaps anæsthetizes, the gastric mucous membrane, as may be inferred from the many cases of gastric hyperæmia and irritation in which it allays *nausea* and *vomiting*. It may therefore be sometimes used with advantage when the stomach is disordered, although fever may be absent. Either solution may have its diaphoretic power increased by the addition of spirit of nitrous ether, of solution of morphia, or of antimonial wine or tartar emetic in very small, non-nauseating doses.

The *dose* of neutral mixture is a tablespoonful; of the effervescing mixture a tablespoonful of each of the two solutions should be mixed, and swallowed while effervescing. The dose should be repeated every hour until the object in view is attained or defeated.

LIQUOR POTASSII PERMANGANATIS, *U. S.*—SOLUTION OF PERMANGANATE OF POTASSIUM.

Liquor potassæ permanganatis, Br.—*Soluté de permanganate de potasse*, Fr.; *Flüssiges übermangansaures Kali*, G.

Preparation.—Take of Permanganate of Potassium sixty-four grains; Distilled Water a pint. Dissolve the permanganate of potassium in the distilled water. *U. S.*

Take of Permanganate of Potash eighty grains; Distilled Water one pint (imperial). Dissolve. *Br.*

Both solutions contain four grains of the permanganate in the fluidounce, and have the purple color and the chemical behavior of the salt.

Medical Uses.—The officinal solution, of four grains of the salt to an ounce of distilled water, appears unnecessary, since it is too weak for many purposes, and too strong for others. For its uses and doses, see Potassii permanganas.

LIQUOR SODÆ, *U. S.*, *Br.*—SOLUTION OF SODA.

Liquor natri caustici, P. G.; *Natrum hydricum solutum.*—*Soude caustique liquide*, Fr.; *Aetznatronlauge*, G.

Specific gravity of the officinal solutions: 1.071, U. S.; 1.047, Br.; 1.330 to 1.334, P. G., F. P.

A solution of $HNaO$ in water.

Preparation.—Take of Carbonate of Sodium twenty-six troyounces; Lime eight troyounces; Distilled Water a sufficient quantity. Dissolve the carbonate of sodium in three pints and a half of distilled water, and heat the solution to the boiling point. Mix the lime with three pints of distilled water, and, having heated the mixture to the boiling point, add it to the hot solution of the carbonate, and boil for ten minutes. Then transfer the whole to a muslin strainer, and, when the liquid portion has passed, add enough distilled water, through the strainer, to make the strained liquid measure six pints. Lastly, keep the liquid in well-stopped bottles of green glass.

Solution of soda has the specific gravity 1.071, and contains five and seven-tenths per cent. of hydrate of sodium. *U. S.*

Take of Carbonate of Soda twenty-eight ounces; Slaked Lime twelve ounces; Distilled Water one gallon. Dissolve the carbonate of soda in the water; and, having heated the solution to the boiling point in a clean iron vessel, gradually mix with it the slaked lime, and continue the ebullition for ten minutes with constant stirring. Then remove the vessel from the fire; and, when by the subsidence of the insoluble matter the supernatant liquor has become perfectly clear, transfer it by means of a siphon to a green-glass bottle furnished with an air-tight stopper, and add distilled water, if necessary, to make it correspond with the tests of specific gravity and neutralizing power. *Br.*

Properties.—What has been stated with regard to the preparation and the properties of potassa solution applies equally well to the solution of soda. The latter does not yield a precipitate with platinic chloride, and with excess of tartaric acid only in concentrated solution. 458 grains by weight (1 fluidounce) of solution of the British Pharmacopœia require for neutralization 470 grain-measures of the volumetric solution of oxalic acid, corresponding to 18.8 grains (4.1 per cent. by weight) of sodium hydrate.

The following table by Gerlach (1869) gives the specific gravity at 15° C. (59° F.) of soda solution containing from 1 to 60 per cent. of sodium oxide and the same percentage of sodium hydrate:—

Percentage.	Na_2O	NaHO	Percentage.	Na_2O	NaHO	Percentage.	Na_2O	NaHO
1	1.015	1.012	21	1.300	1.236	41	1.570	1.447
2	1.029	1.023	22	1.315	1.247	42	1.583	1.456
3	1.043	1.035	23	1.329	1.258	43	1.597	1.468
4	1.058	1.046	24	1.341	1.269	44	1.610	1.478
5	1.074	1.059	25	1.355	1.279	45	1.623	1.488
6	1.089	1.070	26	1.369	1.290	46	1.637	1.499
7	1.104	1.081	27	1.381	1.300	47	1.650	1.508
8	1.119	1.092	28	1.395	1.310	48	1.663	1.519

Pharmaceutical Uses.—In preparing Antimon. sulphurat., Bismuthi oxid., *Br.;* Cinchon. sulph., *U. S.;* Ferri oxid. magnet., Ferri peroxid. humid., Hydrarg. oxidi flav., Quiniæ sulph., *Br.;* Soda (Soda caust.), *U. S.*, *Br.;* Sodæ valerianas, *Br.*

Medical Uses.—This preparation is seldom used therapeutically, and chiefly in cases of "torpor of the liver." *Dose*, ten to sixty drops largely diluted.

LIQUOR SODÆ ARSENIATIS. See SODII ARSENIATIS.

LIQUOR SODÆ CHLORINATÆ, *U. S.*—SOLUTION OF CHLORINATED SODA.

Liquor sodæ chloratæ, Br.; *Liquor natri chlorati*, P. G.; *Liquor natri hypochlorosi.—Labarraque's solution*, E.; *Chlorure de soude liquide, Liqueur de Labarraque*, Fr.; *Chlornatronlösung, Bleichflüssigkeit*, G.

A solution of $NaCl.NaClO$ in water.

Preparation.—Take of Chlorinated Lime twelve troyounces; Carbonate of Sodium twenty-four troyounces; Water twelve pints. Dissolve the carbonate of sodium in three pints of the water, with the aid of heat. Triturate the chlorinated lime, a little at a time, with small portions of the water, gradually added, until a smooth, uniform mixture is obtained. Mix this intimately with the remainder of the water, and set the mixture aside for twenty-four hours. Then decant the clear liquid, and, having transferred the residue to a muslin strainer, allow it to drain until enough liquid has passed to make, with the decanted liquid, eight pints. Mix this thoroughly with the solution of carbonate of sodium, transfer the mixture to a muslin strainer, and allow it to drain; adding water, if necessary, towards the close, until eleven pints and a half of liquid have passed. Lastly, keep the liquid in well-stopped bottles, protected from the light. *U. S.*

Take of Carbonate of Soda twelve ounces; Black Oxide of Manganese four ounces; Hydrochloric Acid fifteen fluidounces; Distilled Water two pints. Dissolve the carbonate of soda in thirty-six fluidounces of the distilled water, and put the solution into a glass vessel. Mix the oxide of manganese and hydrochloric acid in a glass flask with a bent tube attached by means of a cork to its mouth, apply a gentle heat, and with a suitable arrangement of apparatus cause the gas which is evolved to pass first through a wash-bottle containing four ounces of water and then into the solution of carbonate of soda, regulating the heat so that the gas shall be slowly but constantly introduced. When the disengagement of chlorine has ceased, transfer the solution in which it has been absorbed to a stoppered bottle, and keep it in a cool and dark place. *Br.*

The process of the U. S. Pharmacopœia yields the chlorinated soda by double decomposition of chlorinated lime with sodium carbonate, whereby calcium carbonate is precipitated, the chlorinated soda remaining in solution together with the sodium chloride resulting from the decomposition of the chloride of calcium present in the lime compound. No heat being employed after mixing the solutions, the calcium carbonate separates in a very light condition, and retains much of the liquid. The processes of the French and German Pharmacopœias are based upon the same reaction, but the strength of the resulting solution must vary very considerably, 1 part of chlorinated lime being used for a total quantity of water amounting to 7.5 parts, German Pharmacopœia, 16 parts (nearly), U. S. Pharmacopœia, and 45 parts, French Codex.

By the British Pharmacopœia chlorine gas is directed to be passed into the dissolved sodium carbonate, whereby one-half of the salt is acted upon, resulting in the production of chloride and hypochlorite of sodium, and the liberation of carbonic acid which unites with the other half of the salt to bicarbonate of sodium; $2Na_2CO_3 + Cl_2 + H_2O$ yields $NaCl.NaClO + 2NaHCO_3$. If the action of chlorine is continued, the hypochlorite of sodium is decomposed, chloride of sodium and hypochlorous anhydrid being formed; $NaClO + Cl_2$ yields $NaCl + Cl_2O$. This last-mentioned compound, which has a yellowish color, seems to decompose the bicarbonate with difficulty, so that if an excess of chlorine has been used, the solution will contain chloride of sodium, bicarbonate of sodium, and free hypochlorous anhydrid.

Properties and Tests.—The solution is clear and colorless, not greenish-yellow as described by the U. S. Pharmacopœia, a yellowish color being imparted only when the process of the British Pharmacopœia has been followed and an excess of chlorine has been used. It has a feeble odor of chlorine, and a saline, somewhat styptic and sharp taste, and bleaches vegetable colors like chlorine, but less energetically. On the addition of hydrochloric acid effervescence takes place, the gas consisting of carbonic acid and chlorine, the latter resulting from the mutual reaction of the hydrochloric and hypochlorous acids, thus: $NaCl.NaClO + 2HCl = 2NaCl + HCl + HClO$, and $HCl + HClO = Cl_2 + H_2O$. It is upon the amount of this *available chlorine* that the value of this preparation depends; and the British Pharmacopœia determines it by adding 70 grains of the solution to a solution of 20 grains of potassium iodide in 4 fluidounces of water, and acidulated with 2 fluidrachms of hydrochloric acid. The chlorine set free liberates an equivalent quantity of iodine, which imparts to the solution a brown color, to discharge which 500 grain-measures of the volumetric solution of hyposulphite of sodium should be required.

A preparation analogous to the preceding in composition and identical in bleaching effects, is *Liquor potassæ chlorinatæ*, *Chlorinated potassa solution*, which is perhaps better known by its French designation *Eau de javelle.* It is obtained by substituting equivalent quantities of potassium carbonate for the sodium carbonate ordered in the above processes.

Physiological Action.—In animals it produces violent gastro-intestinal irritation, spasms, and death. In man the same symptoms occur from poisonous doses, together with the phenomena of collapse. In medicinal doses it appears to increase the perspiration and urine, to repress mucous profluvia, and lessen glandular enlargements. It also tends to prevent or suspend gangrenous ulceration.

Medical Uses.—Under the impression that its antiseptic qualities fitted it to counteract morbid processes which were theoretically supposed to depend upon putridity, it has been largely employed in *typhoid* fever and typhoid diseases generally, but without obvious advantage. But as a topical application to *gangrenous sores*, and to other *unhealthy ulcers*, such as affect the mouth in *mercurialization*, in *diphtheria*, *scarlatina*, and *scurvy*, the nostrils in *ozæna*, the *uterus*, the *vagina*, and the *auditory canal*, it corrects the offensive odor of the secretions, and stimulates the parts to separate dead tissue and to assume a healthy action. For *simple ulcers* of an indolent aspect, especially such as result from *burns*, or which affect the *nipples* and the *genital organs* of females, this liquid generally acts as a wholesome stimulant.

It may be given internally in *doses* varying from thirty to sixty drops in water or some mild liquid, and repeated every two or three hours. As a gargle it should be diluted with *eight or ten* parts of water, and used of the same strength as an injection into the vagina, uterus, or bladder, and as a lotion for burns, excoriations, and cutaneous eruptions.

LIQUOR SODÆ EFFERVESCENS, *Br.*—EFFERVESCING SOLUTION OF SODA.

Aqua sodæ effervescens, *Aqua alcalina effervescens.*—*Soda water*, E.; *Eau alcaline gazeuse*, Fr.; *Sodawasser*, G.

Preparation.—Take of Bicarbonate of Soda thirty grains; Water one pint. Dissolve the bicarbonate of soda in the water, and filter the solution; then pass into it as much pure washed carbonic acid gas, obtained by the action of sulphuric acid on chalk, as can be introduced with a pressure of seven atmospheres. Keep the solution in bottles securely closed, to prevent the escape of the compressed gas. *Br.*

This corresponds to the effervescing solution of potash (see page 847), and has the same physical properties. Ten fluidounces, after being boiled for five minutes, require for neutralization 178 grain-measures of the volumetric solution of oxalic acid. *Br.*

The corresponding solution of the French Codex is made by dissolving 3.12 grams (48 grains) of bicarbonate of sodium, 0.23 grm. (3½ grains) bicarbonate of potassium, 0.35 grm. (5½ grains) sulphate of magnesium, and 0.08 grm. (1¼ grains) of chloride of sodium in 650 grms. (21 troyounces) of water, and impregnating the solution with carbonic acid gas.

Medical Uses.—This preparation appears to be superfluous. The quantity of bicarbonate of sodium required in any particular case can be administered in carbonated water.

LIQUOR SODII ARSENIATIS, *U. S.*—SOLUTION OF ARSENIATE OF SODIUM.

Liquor sodæ arseniatis, Br.—*Solution of arseniate of soda*, E.; *Liqueur (Soluté) d'arseniate de soude*, Fr.; *Arsensaure Natronlösung*, G.

Preparation.—Take of Arseniate of Sodium rendered anhydrous by a heat not exceeding 300° F. sixty-four grains; Distilled Water a pint. Dissolve the arseniate of sodium in the water. *U. S.*

Take of Arseniate of Soda (rendered anhydrous by a heat not exceeding 300° F.) four grains; Distilled Water one fluidounce. Dissolve. *Br.*

The *Liqueur arsenical de Pearson* of the French Codex is made by dissolving one part of crystallized arseniate of sodium in 600 parts of distilled water, and is, therefore, only about one-tenth the strength of the above, which contain one part of the exsiccated salt in 114 *U. S.* and 110 *Br.* parts.

The solutions are colorless, and give the reactions of arseniate of sodium, which see.

Medical Uses.—This preparation does not appear to possess any demonstrable advantages over the solution of arsenite of potassium. It may be employed in similar *doses*, or from three to five drops, largely diluted, and after meals.

LIQUOR STRYCHNIÆ, *Br.*—SOLUTION OF STRYCHNIA.

Soluté de strychnine, Fr.; *Strychninlösung*, G.

Preparation.—Take of Strychnia in crystals four grains; Diluted Hydrochloric Acid six minims; Rectified Spirit two fluidrachms; Distilled Water six fluidrachms. Mix the hydrochloric acid with four drachms of the water, and dissolve the strychnia in the mixture by the aid of heat. Then add the spirit and the remainder of the water. *Br.*

Medical Uses.—This solution, being stable, is convenient for medical prescription. The *dose* is from five to ten minims, *i. e.*, from one-twenty-fourth to one-twelfth of a grain of muriate of strychnia.

LIQUOR ZINCI CHLORIDI, *U. S.*, *Br.*—SOLUTION OF CHLORIDE OF ZINC.

Chlorure de zinc liquide, *Solution de Burnett*, Fr.; *Flüssiges Chlorzink*, G.

Preparation.—Take of Zinc in small pieces six troyounces; Nitric Acid, Precipitated Carbonate of Zinc, each one hundred and fifty grains; Muriatic Acid, Distilled Water, each a sufficient quantity. To the zinc, contained in a glass or porcelain vessel, add gradually enough muriatic acid to dissolve it; then strain the solution, add the nitric acid, and evaporate to dryness. Dissolve the dry mass in five fluidounces of distilled water, add the precipitated carbonate of zinc, and agitate the mixture occasionally during twenty-four hours; then filter through paper, adding enough distilled water, through the filter, to make the liquid measure a pint. *U. S.*

Take of Granulated Zinc one pound; Hydrochloric Acid forty-four fluidounces; Solution of Chlorine a sufficiency; Carbonate of Zinc half an ounce, or a sufficiency; Distilled Water one pint. Mix the hydrochloric acid and water in a porcelain dish, add the zinc, and apply a gentle heat to promote the action until gas is no longer evolved. Boil for half an hour, supplying the water lost by evaporation, and allow the product to cool. Filter it into a bottle, and add solution of chlorine by degrees, with frequent agitation, until the fluid acquires a permanent odor of chlorine. Add the carbonate of zinc, in small quantities at a time, and with renewed agitation, until a brown sediment appears. Filter the liquid into a porcelain basin, and evaporate until it is reduced to the bulk of two pints. *Br.*

Zinc dissolves in hydrochloric acid with the evolution of hydrogen gas, $Zn_2 + 4HCl$ yields $2ZnCl_2 + 2H_2$. The iron contained in the solution is first oxidized in the one case by nitric acid, and in the other by chlorine gas. To avoid contamination with nitrate, the former solution is evaporated to dryness, redissolved in water, and then treated with zinc carbonate, whereby ferric oxide is precipitated. The process of the British Pharmacopœia arrives at the same result in a similar manner, except that an evaporation of the liquid to dryness is not resorted to. 1 pound of zinc yields about 24½ ounces of zinc chloride, which are contained in 40 (imperial) fluidounces of the solution. The formula of the U. S. Pharmacopœia yields about 9¼ troyounces of zinc chloride, dissolved to make one apothecaries' pint. The two preparations are, therefore, practically identical.

Properties.—The solution is a colorless and inodorous liquid, which has the disagreeable metallic taste of zinc salts, and is miscible with alcohol and water. Its reactions and tests are those of *Zinci chloridum*, which see. Ch. Bullock (1868) determined the specific gravity of some solutions of this salt, marked *, and, by calculating the remainder, constructed the following table, giving the percentage of anhydrous zinc chloride. The specific gravities ascertained by Kremers (1858) differ somewhat from these results; but the figures given by R. Hoffmann (Tabellen, etc., 1877) are considerably larger for the solutions containing over 9 per cent. of $ZnCl_2$.

The French Codex directs the dissolving of 1 part of fused chloride of zinc in 2 parts of water, the solution to be of specific gravity 1.33. Sir Wm. Burnett's liquid contained 200 grains of zinc in the imperial fluidounce, and was stated to have the specific gravity 2.0; it contained about 50 per cent. of $ZnCl_2$.

Medical Action and Uses.—Under the name of *Burnett's Disinfecting Fluid* a solution of chloride of zinc was extensively employed, and its utility probably suggested an officinal preparation for similar purposes. That solution has in numerous cases produced fatal mischief by being taken internally, occasioning all the phenomena belonging to a violent irritant poison, leaving in the mouth, œsophagus, and alimentary canal traces of its corrosive action, and giving the intestinal walls a leathery aspect and consistence. In some cases it is stated that the dead body showed no signs of putrefaction. The chief application of this solution is to deodorizing and disinfecting sinks, sewers, water-closets, dissecting-rooms, hospitals, etc. It has been made use of to preserve dead bodies by injecting it into the bloodvessels; but owing to its corrosive action upon steel, such bodies are not suitable for dissection. Largely diluted (gtt. x to gtt. xx in water f℥iv) it has been used as an injection for *gonorrhœa* in both sexes, and for *leucorrhœa;* also as a collyrium in *gonorrhœal*, and in *diphtheritic ophthalmia.* It should be employed, if at all, with extreme caution, the weakest solution being first applied to test the susceptibility of the parts.

LIRIODENDRON, *U. S.*—TULIP TREE BARK.

White poplar bark, E.; *Écorce de tulipier*, F.; *Tulpenbaumrinde*, G.

The bark of Liriodendron tulipifera, *Lin.* *Nat. Ord.*—Magnoliaceæ.

Origin.—The tulip tree or tulip poplar is a stately tree, 100 to 140 feet high, which is found in woodlands and rich soil throughout the United States from New England to Michigan and Illinois, and southward to the Gulf of Mexico. Its leaves are alternate, petiolate, broad, three-lobed, with the terminal lobe broadest, and emarginately truncate. The large flowers, which appear in May, are tulip-shaped, and have three sepals and six greenish-yellow, near the base orange-red petals. The fruit consists of flat, indehiscent, one- or two-seeded capsules with lance-oblong wings above, and cohering together in an elongated cone. The bark is collected from the branches, and also from the trunk.

Description.—The branch bark is in curved pieces or quills, which have a brown- or blackish-gray to purplish-brown outer surface, marked with numerous small warts, their shallow scars or confluent lines forming more or less regular, elongated meshes, which become longitudinally cleft in the older bark. The fissured, gray, corky layer is removed from the trunk bark, which then consists exclusively of liber, has a pale-yellowish color, and a smooth, very finely and closely striate inner surface. The dry bark breaks, when young, with a short, the older with a fibrous fracture, and shows, upon cross-section, broad wedges of medullary rays, and in the inner layers tangential rows of bast fibres. The similar root bark has a darker color. The slight odor of the fresh bark disappears almost completely on drying; the taste is somewhat pungently aromatic and bitter, combined with some astringency. When long kept the bark is said to become insipid; bark collected by us ten years ago, and kept in a dry place without special precaution, has still the characteristic taste in a marked degree.

Constituents.—The most important constituent appears to be the *liriodendrin* of Prof. Emmet (1831), which he obtained crystallized by concentrating the tincture made with strong alcohol, adding water until a permanent turbidity commences to appear, and evaporating spontaneously. It forms white needles or prisms and small scales, insoluble in water, soluble in alcohol and ether, fusible at about 82° C. (180° F.), and volatilizing partly undecomposed near 132° C. (270° F.). It is contained in the infusion of the bark, and precipitated from it by an alkali. A portion is always obtained in an amorphous condition, but has the same bitter and pungent taste as the crystallized. Wallace Procter (1872) did not succeed in obtaining it crystallized by treating the alcoholic extract with petroleum-benzin; it separated in transparent, yellowish globules of a persistently bitter and acrid taste.

Medical Uses.—Used popularly as a domestic tonic by the country people, it was first introduced into medicine, as a tonic, by Dr. Benjamin Rush, who ascribed to it only the virtues of a simple bitter. Like other bitters, it has had some repute as a vermifuge, and as an antiperiodic; and, in warm infusion, as a diuretic and sudorific. The *dose* of the powder is one or two drachms. An infusion or decoction may be prepared with an ounce of the bark in a pint of water, and given in the dose of two fluidounces. A saturated tincture may be prescribed in the dose of a fluidrachm.

LITHII BROMIDUM.—BROMIDE OF LITHIUM.

Bromure de lithium, Fr.; *Bromlithium*, G.
Formula LiBr. Molecular weight 87.

Preparation and Properties.—This salt is readily soluble in water and alcohol, 100 parts of the former liquid dissolving at 0° C. (32° F.) 143 parts, and at 34° C. (93.2° F.) 196 parts of the bromide. According to Yvon (1875), it may be prepared by dissolving lithium carbonate in hydrobromic acid and evaporating. Or 37 grams of the carbonate are converted into neutral sulphate, dissolved in a small portion of water, and mixed with a concentrated aqueous solution of 119 grams of potassium bromide. The mixture is well stirred, the liquid separated by filtration, evaporated to dryness, and treated with alcohol, which leaves potassium sulphate undissolved; the alcoholic solution is evaporated to dryness. Lithium bromide may be obtained in crystals by evaporating its syrupy solution over sulphuric acid. The anhydrous salt contains nearly 92 per cent. of bromine.

Medical Action and Uses.—In 1870 Dr. S. Weir Mitchell accidentally found that bromide of lithium seemed to cause a more rapid and intense sleepiness than the other bromides. He observed, moreover, that it was the most soluble salt of its class, that it contained a larger proportion of bromine than any other, and that, clinically, it excels them all as a hypnotic, and is efficient in smaller doses than the bromide as an anti-epileptic. In 1877 he declared of this salt that it had stood the test of his own experience as well as that of many French and German therapeutists, who had come to regard it as the most valuable of the bromides. According to Levy, its action, compared with that of potassium bromide, is as follows: It acts with greater force and rapidity upon the spinal cord and nerves; the anæsthesia it produces begins in the nerves and is propagated to the cord; in other words, it is a sedative of morbid excitement in the spinal cord. It does not appear to act upon the heart.

Bromide of lithium was used in the treatment of *epilepsy*, as already stated, and apparently with very remarkable advantages; but its efficiency was differently estimated by some other physicians, of whom Echeverria regarded it as inferior to the potassium bromide, and Sée prescribed it without any favorable results. It has been given in this disease in the *dose* of from five to ten grains three times a day, in a simple bitter infusion. But much larger doses may be prescribed. It has also been used in *gout* with no demonstrable advantage.

LITHII CARBONAS, *U. S.*—CARBONATE OF LITHIUM.

Lithiæ carbonas, Br.; *Lithium carbonicum*, P. G.; *Carbonas lithicus*.—*Carbonate of lithia*, E.; *Carbonate de lithine*, *Carbonate lithique*, Fr.; *Kohlensaures Lithion*, G.
Formula Li_2CO_3. Molecular weight 74.

Origin and Preparation.—Lithium is met with as phosphate in *montebrasite* and several other minerals, and as fluoride or silicate in *lepidolite*, *spodumene*, and others. It is found in minute quantities in the ashes of some plants, and in many mineral springs, often as carbonate; the waters of the Mur-spring at Baden-Baden, and of a hot spring at Wheel-Clifford, in Cornwall, are the richest known; the latter, according to W. A. Miller (1864), containing 26.05 grains LiCl in the imperial gallon. To prepare the carbonate lepidolite is heated with sulphuric acid, the aqueous solution treated with lime to separate metallic oxides and earths, and then precipitated by potassium carbonate, or neutralized with muriatic acid and evaporated. From the residue the chloride of lithium is dissolved by a mixture of alcohol and ether, and thus freed from the chlorides of rubidium, cæsium, sodium, and potassium, with which metals it is associated in the lepidolite. The concentrated aqueous solution of lithium chloride, treated with ammonium carbonate, yields a precipitate of lithium carbonate, which is washed with alcohol.

Properties.—Carbonate of lithium is a light white powder, or is in minute crystalline grains, fuses at a dull red heat with the evolution of some carbonic acid, and, after congealing, may be broken into pearly pieces. It is insoluble in alcohol, but dissolves in about 100 parts of water; the solution precipitates the salts of the heavy metals, and, on boiling, decomposes the ammonium salts. It dissolves with effervescence in dilute hydrochloric acid, and the solution evaporated to dryness leaves a residue of lithium chloride, which imparts a carmine color to the flame of a spirit lamp. The neutral solution of the chloride yields a white precipitate with phosphate of sodium.

Tests.—Magnesium and calcium salts are the principal impurities; salts of heavier metals are rarely present. The salt, dissolved in hydrochloric acid, should yield no precipitate with hydrogen sulphide either before or after neutralization with ammonia. The same solution yields no precipitate with sulphuric acid (*barium*), nor after neutralization with ammonium oxalate (*calcium*) or lime-water (magnesium). Ten grains of the salt, neutralized with sulphuric acid and heated to redness, leave 14.86 grains of dry sulphate of lithium (*Br.*). Alkaline impurities are detected, after being converted into chlorides, by their insolubility in a mixture of equal volumes of alcohol and ether, as stated above.

Off. Prep.—Liquor lithiæ effervescens, *Br.;* Lith. citras, *U. S.*, *Br.*

Chemical Action.—When a calculus composed of uric acid and oxalate of lime is suspended in a warm solution of carbonate of lithium it loses sensibly in weight; and when a portion of bone infiltrated with gouty concretions is placed in a solution of the salt, after two or three days the whole of the deposit disappears. In fact, the urate of lithium is the most soluble salt formed with uric acid. These facts have been adduced to explain the efficacy in chronic gout of numerous mineral springs in Europe, and of the Gettysburg Spring in Pennsylvania.

Medical Uses.—Opinions are by no means uniform in regard to the value of carbonate of lithium in removing *uric acid deposits* and *gouty concretions*. On the one hand, it is asserted that when patients are voiding uric acid gravel, it causes the deposit to diminish or to cease altogether; and that, in gout, it often diminishes the frequency of the attacks. At the same time, it is stated to be powerfully diuretic. On the other hand, some authorities confidently affirm that they have seen no benefit arise from its use. Others, again, declare that it is suitable only for the treatment of chronic gout, that the daily dose of it should be small, and that its good effects become apparent only after several weeks' use. On the whole, there appears to be no substantial ground for a belief in its alleged virtues in gout and calculous diseases.

Carbonate of lithium in solution is said to exhibit extraordinary powers in the solution of *false membrane*.

This medicine may be given in the *dose* of from one to three grains three times a day, dissolved in three or four ounces of hot water, or preferably in carbonated water.

LITHII CITRAS, *U. S.*—Citrate of Lithium.

Lithiæ citras, Br.; *Lithium citricum.*—*Citrate of lithia*, E.; *Citrate de lithine*, Fr.; *Citronensaures Lithion*, G.

Formula $Li_3C_6H_5O_7$. Molecular weight 210.

Preparation.—Take of Carbonate of Lithium one hundred grains; Citric Acid in crystals two hundred grains; Distilled Water two fluidounces. Dissolve the citric acid in the water gently heated, and to the solution gradually add the carbonate of lithium until perfectly dissolved, heating the solution so long as effervescence is produced. Evaporate, by means of a steam- or sand-bath, to a viscid consistence, dry the residue in an oven, at a temperature of about 240° F.; then rapidly pulverize it, and preserve the powder in a well-stopped bottle. *U. S.*

Take of Carbonate of Lithia fifty grains; Citric Acid in crystals ninety grains; Warm Distilled Water one fluidounce. Dissolve the citric acid in the water, and add the carbonate of lithia in successive portions, applying heat until effervescence ceases, and a perfect solution is obtained. Evaporate by a steam- or sand-bath till water ceases to escape, and the residue is converted into a viscid liquid. This should be dried in an oven or air-chamber at the temperature of about 240° F., then rapidly pulverized and inclosed in a stoppered bottle. *Br.*

Both formulas direct the acid and carbonate nearly in the proportion in which they combine, the first having a slight excess of citric acid, the second of lithium carbonate. Carbonic acid is given off, and the reaction may be thus represented: $3Li_2CO_3+2H_3C_6H_5O_7$ yields $2Li_3C_6H_5O_7+3CO_2+3H_2O$. The yield is equal to the weight of citric acid used.

Properties.—Lithium citrate is a white and amorphous powder, which dissolves in 25 parts of water, and may be obtained crystallized from a concentrated solution on standing. When heated, it blackens, gives off the odor of burning citric acid, inflammable gases are evolved, and finally a white residue is left, which, if neutralized with hydrochloric acid, is soluble in alcohol, and the solution, ignited, burns with a carmine-colored flame. 20 grains of the salt, when heated to low redness with free access of air, leave a residue weighing 10.6 grains. The salt is recognized as a citrate by mixing its aqueous solution with calcium chloride, filtering, and heating the clear liquid, when again a precipitate of calcium citrate will be deposited.

Tests.—Other acids beside citric are detected by their several tests. Basylous impurities are recognized by igniting some of the salt, dissolving the residue in hydrochloric acid, evaporating to dryness, redissolving in water, and testing as described in the preceding article.

Other Lithium Salt.—LITHII BENZOAS, *Benzoate of lithium*, has been recommended by Shuttleworth (1875). It is prepared by heating a mixture of 1 oz. of lithium carbonate and 9 ozs. of water, adding gradually $3\frac{1}{4}$ ozs. of benzoic acid, or as long as effervescence is produced, filtering and evaporating to dryness. The yield is nearly $3\frac{1}{2}$ ozs. The salt is soluble in $3\frac{1}{2}$ parts of cold and $2\frac{1}{2}$ parts of boiling water, and in 10 parts of cold alcohol specific gravity 0.838.

Medical Action.—Like the vegetable salts of sodium and potassium, the citrate of lithium is decomposed in the body, and excreted as a carbonate with the urine. Its operation is the same as that of the carbonate of lithium.

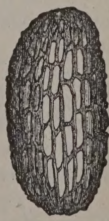
The scarcity and high price of lithium salts necessarily limit their use.

LOBELIA, *U. S.*, *Br.*—LOBELIA.

Herba lobeliæ, P. G.—*Indian tobacco*, E.; *Herbe de lobélie enflée*, Fr.; *Lobelienkraut*, G.

The leaves and tops of Lobelia inflata, *Lin.* Barton, Med. Bot., t. 16; Bentley and Trimen, Med. Plants, 162. *Nat. Ord.*—Lobeliaceæ.

Fig. 100.



Lobelia Seed, magnified.

Origin.—The inflated lobelia is an annual herb, native of the North American continent, growing in dry open fields and on the borders of woods, from the northern parts of Canada, southward throughout the United States to Georgia and Mississippi. It flowers from July to September, and should be collected when some of the capsules have ripened.

Description.—The herb grows from 12 to 20 inches high, has a branching stem, which is somewhat furrowed and beset with spreading hairs. The leaves are alternate, two to three inches long, ovate or oblong, irregularly toothed, pubescent, and pale green; the lower ones petiolate, the upper sessile and gradually reduced to bracts. The flowers are in long racemes, terminating the stem and branches. The calyx tube is adherent to the ovary, has the limb divided into five narrow teeth, and becomes inflated in fruit. The pale-blue corolla is somewhat two-lipped, and has the upper side of the tube split to the base. The five stamens are free from the corolla, and by the union of the filaments and anthers form a tube which incloses the single style. The fruit is a thin sub-globular capsule, which is two-celled, opens at the apex, and contains a large number of minute brown oblong seeds, the surface of which has, under the microscope, a reticulated appearance. It has an herbaceous, somewhat irritating odor, and an herbaceous, afterwards burning and acrid tobacco-like taste.

Constituents.—Lobelia owes its virtues, at least in part, to an alkaloid, *lobelina*, which was first recognized by Calhoun (1833), but isolated by Procter (1838). To obtain it, the tincture made with alcohol containing acetic acid is evaporated to a syrupy consistence, triturated with excess of magnesia, the filtrate agitated with ether, and the ethereal solution evaporated; the impure alkaloid requires purification by combining with an acid, treating with animal charcoal, and again decomposing with magnesia. W. D. Richardson (1872) obtained more alkaloid from the above mother liquor by precipitation with potassium iodo-hydrargyrate. *Lobelina* is a yellow, somewhat aromatic liquid, having an acrid taste; it is lighter than water, is soluble in alcohol, ether, and fixed oils, and less so in water. Its salts, except the acetate, are crystallizable, are freely soluble in water, scarcely so in ether, and not altered by a boiling temperature; whereas the alkaloid is thereby deprived of its acrid taste. Richardson found it even to be altered by simple exposure to air, whereby it became resinified and unable to combine with acids. Bastick (1850) considers it volatile, but to evaporate not entirely unchanged.

In 1871 Enders obtained the acrid principle *lobelacrin* by concentrating the tincture in the presence of charcoal, washing this with water, and exhausting with boiling alcohol (Pharmacographia). It forms warty tufts of a brown color, is soluble in ether and chloroform, slightly so in water, is decomposed by boiling with water, and yields sugar and *lobelic acid* under the influence of acids and alkalies. It is possible that the alkaloid, as heretofore obtained, has been more or less contaminated with this body.

The *lobelic acid* of Enders is probably identical with the compound of Pereira (1842) and Procter bearing the same name. Procter obtained it from the decoction of the leaves by precipitating it with sulphate of copper and decomposing with hydrogen sulphide. It is crystallizable, soluble in ether, and yields with ferric salts an olive-brown, with copper sulphate a light-green, and with lead acetate and baryta water a yellow precipitate. The barium compound of Enders's acid is soluble in water.

Reinsch (1848) obtained from the herb also waxy, resinous, fatty, and gummy matters, and Procter from the seeds about 30 per cent. of rapidly drying fixed oil.

Allied Species. LOBELIA SYPHILITICA, *Lin.*, *Great Lobelia.*—It is two to three feet high, has acute elliptic-oblong, irregularly serrate leaves, and showy blue flowers in the axils of the upper leaves, forming a terminal raceme; the calyx has a short hemispherical tube, five long acute lobes, and at their base conspicuous deflexed appendages. It is met with in low grounds in the United States.

LOBELIA CARDINALIS, *Lin.*, *Cardinal plant.*—It is common in marshy and low grounds throughout the greater portion of the United States, attains a height of two to three feet, is nearly smooth, has oblong lanceolate, acute, and slightly toothed leaves, and bears long racemes of large showy scarlet-red flowers on short pedicels in the axils of the leaf-like bracts.

Off. Prep.—Acet. lobeliæ, *U. S.;* Tinct. lobeliæ, *U. S.*, *Br.;* Tinct. lobeliæ æther., *Br.*

Physiological Action.—The effects produced by lobelia and its alkaloid upon animals are almost identical with those of tobacco and nicotia, but larger doses are required to develop them. It is ranked as a respiratory poison, and in the cat it greatly reduces the temperature.

The symptoms caused by lobelia in man are: nausea, salivation, malaise, præcordial distress, dyspnœa and dysphagia, burning and rawness in the fauces, eructation, vomiting, urination; general muscular relaxation, the pulse becoming small, irregular, and slow; and, when the dose has been very excessive, extreme prostration, anxiety, contracted pupils, insensibility, and occasionally death, preceded by convulsions. A large number of cases have been published of death from the maladministration of this drug by ignorant persons assuming to be practitioners of medicine.

Medical Uses.—The chief medicinal value of lobelia is in the treatment of *asthma*, whether the disease be purely spasmodic or associated with pulmonary emphysema, chronic bronchitis, heart disease, etc. It eliminates from the attack the bronchial spasm, which in the first-named affection constitutes the whole disease, and in the others a complication only. A fluidrachm of the tincture should be given every hour, or, if the symptoms are urgent, every half hour, until relief is obtained, or the characteristic effects of the medicine are produced. Its efficacy in the other diseases mentioned, as well as in *whooping cough*, will depend mainly upon the predominance of the nervous element in them; whenever the dyspnœa is due less to spasm than to inflammatory changes in the bronchia, or depends upon the presence in these tubes of secreted matters, lobelia displays no special virtues that entitle it to be preferred before numerous "expectorants." Thus, while it is of no more advantage in *inflammatory laryngitis* than various other nauseants and emetics, it is decidedly more efficacious in *spasmodic laryngitis* than most other remedies.

The *dose* of lobelia as an emetic is from ten to twenty grains; as an expectorant from one to five grains. The preparations most frequently employed are the tincture and the vinegar of lobelia, of either of which the dose as an expectorant is from ten to sixty minims. In asthmatic attacks one or two fluidrachms should be administered every half hour or hour, according to the urgency of the symptoms.

LOLIUM.—DARNEL.

Bearded darnel, E.; *Ivraie*, Fr.; *Lolch*, *Taumelkorn*, G.

The fruit (caryopsis) of Lolium temulentum, *Lin.*, s. L. arvense, *With.* Bentley and Trimen, Med. Plants, 295.

Nat. Ord.—Graminaceæ.

Origin.—The bearded darnel grows on waysides and in grain-fields in Western Asia and throughout Europe, and has been introduced to some extent in most grain growing countries; it is rare in the United States. It is an annual about 2½ feet high, with rather large leaves, and has an elongated inflorescence, the spikelets being nearly an inch long, about 7-flowered, somewhat compressed, alternate, sessile, appressed to the concave rachis, and about as long as the glumes.

Description.—The fruit is oblong-ovoid, nearly ¼ inch long, inclosed in the paleæ, grooved on the inner and convex on the outer surface, smooth, pale brown, internally white, inodorous, and of a farinaceous, afterwards bitterish, taste.

Constituents.—The chemical investigations undertaken for the purpose of isolating the poisonous principle have been recently (1875) reviewed by Wittstein. The deleterious properties of the plant, according to Ludwig and Stahl

(1864), appear to be due to an acrid fixed oil and to an amorphous yellowish glucoside. Bley (1834) and Muratori (1837) ascribed them to an acid body, and Baillet and Filhol (1863) to a non-saponifiable oily compound. The fruit contains the ordinary constituents of grain, among them from 30 to 50 per cent. of starch, the granules of which, according to Schwerdtfeger (1853), are about one-third the size of wheat starch, circular, with a moderately wide margin, and a bright, strongly translucent surface without marks.

LOLIUM PERENNE, *Lin.*, called *ray-* or *rye-grass*, is a pasture grass, has a perennial creeping rhizome, the glumes shorter than the spikelets, and awnless or short-awned flowers. It is not poisonous.

Medical Action and Uses.—A large number of persons have at different times been poisoned by bread made with flour containing lolium. Upon different animals it acts differently; it is poisonous to dogs, sheep, and horses, but not to hogs, cows, and ducks, and quails are said to be fond of the seeds as food. Its effects have been known from ancient times to be narcotic and anæsthetic. They comprise the following symptoms: headache, vertigo, disturbed and sometimes yellow vision, ringing in the ears, paresis of the tongue, oppression in breathing, anxiety, vomiting and sometimes purging, urination, general muscular trembling, cold sweating, and overpowering and deep sleep. In several cases the poisoning has proved fatal. There is reason to suspect that the old custom of using darnel to adulterate malt and distilled liquors is not wholly obsolete. The peculiar intoxication produced by some of these drinks strongly suggests such a fraudulent and wicked addition to them. Lolium has been mixed with poultices applied for the relief of local *pains*, pleuritic, neuralgic, and rheumatic; and, although it has been given internally, neither the grounds of its administration nor its alleged results are entitled to any confidence.

LOTIONES.—LOTIONS.

Washes, E.; *Lotions*, Fr.; *Waschungen*, G.

Lotions are liquid preparations, usually containing water as their principal vehicle, and are ordinarily applied by wetting lint or muslin with them, and keeping this upon the affected part.

LOTIO HYDRARGYRI FLAVA, *Br.*—YELLOW MERCURIAL LOTION.

Aqua phagedænica, P. G.—*Yellow wash*, E.; *Eau phagédénique*, *Eau divine de Fernel*, Fr.; *Phagedänisches Wasser*, *Altschadenwasser*, G.

Preparation.—Take of Perchloride of Mercury eighteen grains; Solution of Lime ten fluidounces. Mix. *Br.*

Mix 1 part of powdered corrosive sublimate with 300 parts of lime-water. *P. G.*

A double decomposition takes place, resulting in the formation of calcium chloride and finely divided yellow mercuric oxide. It should be well shaken when used.

Surgical Action and Uses.—This preparation is stimulant or even caustic. Its use is restricted almost exclusively to the treatment of indolent *chancres* and other *syphilitic ulcers*. It should be applied upon lint.

LOTIO HYDRARGYRI NIGRA, *Br.*—BLACK MERCURIAL LOTION.

Aqua phagedænica nigra, P. G.; *Aqua nigra, Aqua mercurialis nigra.—Black wash*, E.; *Eau phagédénique noir*, Fr.; *Schwarzes Wasser*, G.

Preparation.—Take of Subchloride of Mercury thirty grains; Solution of Lime ten fluidounces. Mix. *Br.*

Rub together 1 part of calomel and 60 parts of lime-water. *P. G.*

The chemical reaction between the two substances results in producing calcium chloride and black mercurous oxide. It must be well shaken when used.

Surgical Action and Uses.—The action of black wash appears to be mildly stimulant and astringent as well as protective. It may be applied on lint to *syphilitic* ulcers.

LUPULINA, *U. S.*—LUPULIN.

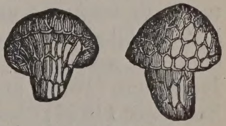
Glandulæ lupuli, P. G.; *Lupulinum.—Lupuline, Lupulite*, Fr.; *Hopfenmehl, Lupulin*, G.

The yellow glandular powder separated from the strobiles of Humulus lupulus, *Lin.*

Origin.—See Humulus, page 702. On handling dry hops the glandular powder becomes detached, and is freed from fragments of the bracts, etc., by sifting; about 10 per cent. of the weight of the hops may be obtained.

Description.—Lupulin when fresh is a brownish-yellow, afterwards yellowish-brown, granular resinous powder, which has the aromatic odor and bitter and aromatic taste of hops. Under the microscope it is seen to consist of two hemispheres, the lower and firmer of which is somewhat obtusely conical or top-shaped, the upper one rounded, the surface of both reticulate. In the dry state the lower one nearly retains its shape, but the more delicate upper part collapses, and forms a flattish hood. The glands contain a brown-yellow liquid which dries up to a resinous mass. Lupulin should be free from sand, which readily subsides from it when agitated with water.

Fig. 101.



Lupulin (fresh).

Constituents.—On distilling hops with water, Personne (1854) obtained *valerianic acid* and a *volatile oil* which boils between 140° and 300° C. (284° and 572° F.), is colorless and neutral, but becomes resinous and acid on exposure, and consists of a lighter portion, $C_{10}H_{16}$, and *valerol*, $C_6H_{10}O$, from which by gradual oxidation valerianic acid is formed. The residue from the distillation when treated with lime yields a distillate of *valeral*, $C_5H_{10}O$. The *resin* of lupulin was examined by Vlaanderen (1858), who found it tasteless, combining with metals, and becoming more hydrated in the course of purification. The principal constituent of lupulin is wax, which Lermer (1863) found to be *myricin* (myricylic palmitate). He also isolated the bitter principle, and called it *lupamaric acid* (Hopfenbittersäure). To prepare it, the ethereal extract of fresh hops is treated with 90 per cent. alcohol, which leaves the wax behind; the alcohol is evaporated, the residue dissolved in ether, and this solution agitated with strong potassa solution to remove resin; agitation with water now dissolves the potassium lupamarate, which is precipitated with copper sulphate, and the precipitate, decomposed by hydrogen sulphide, yields the acid in white crystals, becoming yellow on exposure, insoluble in water, but soluble in alcohol, ether, chloroform, carbon bisulphide, and oil of turpentine. Its composition is $C_{32}H_{50}O_7$.

Off. Prep.—Extract. lupulinæ fluid., Oleores. lupulinæ, Tinct. lupulinæ, *U. S.*

Medical Action and Uses.—The account given of the operation of hop (see Humulus) makes an extended discussion of lupulin unnecessary, since it is upon this product that the virtues of hop chiefly depend. In doses of from twenty to twenty-five grains, lupulin occasions a lively sense of warmth at the epigastrium, which afterwards extends to the whole abdomen. Constipation, with colicky pain, is apt to ensue, but the appetite and digestion appear to be invigorated. It is alleged that full doses of lupulin diminish the frequency of the pulse. It certainly tends to allay the susceptibility which is a frequent cause of an excited circulation. Probably in this manner, rather than by a direct action upon the brain, it favors sleep, and tends to repress that excitement which occasions *priapism* and *seminal emissions*, and *nocturnal incontinence of urine.* It has seemed to allay *irritability of the bladder* when opium was not tolerated. It may be prescribed in *doses* of from five to ten grains and upwards, mixed with jelly or syrup.

LYCIUM.—MATRIMONY VINE.

Lycium vulgare, *Dunal*, s. L. barbarum, *Lin.* *Nat. Ord.*—Solanaceæ.

Description.—This shrub is indigenous to the countries bordering on the Mediterranean, and is cultivated and wild in the United States. It is from 10 to 20 feet high, and has numerous, slender, recurved branches, which are covered with a smooth brownish-gray bark, and armed with few thorns. The leaves are one or two inches long, alternate, oblong-lanceolate, entire, smooth, shortly petiolate and often clustered. The greenish-purple flowers have a tubular five-lobed corolla, and produce oval red two-celled berries, containing many reniform seeds. The bark and leaves have a sweetish and slightly bitter and acrid taste.

Constituents.—An alkaloid, *lycina*, $C_5NH_{11}O_2$, has been isolated by Husemann and Marmé (1863), by precipitating the decoction with subacetate of lead, removing the lead by sulphuric acid, and precipitating the filtrate with phosphomolybdic acid; the precipitate is mixed with prepared chalk, the mixture dried, and the alkaloid dissolved by alcohol. It forms white prisms, which are deliquescent, sparingly soluble in ether, and has an acrid taste free from bitterness. Husemann (1875) proved it to be identical with *betaina*, an alkaloid isolated by Scheibler (1866) from beet-root juice, and, like it, not pre-existing in the plant, but formed from it during the process by the action of free acid. The leaves of lycium yielded a larger proportion than the branches.

Allied Species.—Lycium afrum, *Lin.*, of Northern Africa, and L. umbrosum, *Humb. and B.*, of South America. The infusion of the leaves is used in erysipelas and skin diseases.

Medical Action and Uses.—There is nothing to establish a therapeutical character for lycium, unless it be that lycina in the *dose* of two or three grains causes paralysis in frogs.

LYCOPERDON.—PUFF-BALL.

Lycoperdon solidum, *Gron.*, s. Pachyma cocos, *Fries.*
Nat. Ord.—Fungi, Gasteromycetes.

Origin.—This curious product is found attached to the roots of fir trees, in the southern part of the United States from Virginia westward to Kansas, and is known as *Indian bread*, or *tuckahoe.* It likewise grows in China, where it is used under the name of *füh-ling.* Currey and Kelley consider it to be an altered state of the root of the tree, occasioned by the presence of a fungus, the mycelium of which traverses, disintegrates, and even obliterates the wood and bark. This view is sustained by the results of the analyses made by R. T. Brown (1871) and J. L. Keller (1876).

Description.—The tuckahoe is an irregularly globular or elongated body, varying from a few inches to a foot or more in diameter, and from a few ounces to several pounds in weight. It is externally of an ashy-black, and has a rugose surface; internally it is whitish, fissured, more or less spongy, but firm, of a somewhat farinaceous appearance, sometimes quite compact, and breaks into irregular masses. It is without odor and has an insipid taste.

Constituents.—Brown found it to contain 14 per cent. of water, 0.93 of glucose, 2.63 of gum, 17.34 of pectose, 64.45 of cellulose, and 0.16 per cent. of ash; the nitrogen amounted only to 0.36 per cent. Keller's specimen yielded 77.27 per cent. of pectose, 3.76 of cellulose, and 3.64 of ash, the other constituents being nearly in the same proportion as in the former analysis.

Allied Plants.—Lycoperdon bovista, *Lin.*, s. Bovista gigantea, *Nees;* Common puff-ball, *E.;* Vesse-loup, *Fr.;* Bovist, *G.*—This fungus forms globular or obconical masses, of a more or less yellow color, and varying in size from a few inches to about two feet in diameter. The lower part has a spongy texture, and was formerly used like spunk (see page 652) for arresting hemorrhages.

Lycoperdon cervinum, *Lin.* (Scleroderma, *Pers.;* Elaphomyces, *Fr.*); Puff-ball, *E.;* Truffe de cerf, *Fr.;* Hirschbrunst, *G.*—Its size is about that of a walnut, or smaller. It is brown, verrucose, internally purplish-brown, and was considered to possess stimulant properties.

Tuber cibarium, *Sibth.* (Lycoperdon tuber, *Lin.*); Truffle, *E.;* Truffe, *Fr.;* Trüffel, *G.*—It is of subterraneous growth, subglobular, about the size of a walnut, externally blackish and verrucose, internally white, marbled with brown, fleshy. Like some allied species, it is edible.

Physiological Action and Medical Uses.—In 1853 Dr. B. W Richardson's attention having been directed to the fact that the smoke of the *common puff-ball* had been used in the country for stupefying bees in order to secure the contents of the hive without sacrificing the insects, he conceived the idea that it might be made use of as a surgical anæsthetic. He accordingly experimented upon dogs, cats, and rabbits, and in one case removed a tumor from a dog without any sign of pain being shown during the operation. When a moderate quantity was inhaled gradually, the narcotism came on and passed off slowly, the animal exhibiting all the symptoms of intoxication, with convulsions, and sometimes vomiting. It destroyed life slowly; a dog would inhale the fumes for twenty minutes or half an hour after being completely narcotized, previous to expiring. The heart's beat in all cases survived the respiration. The lungs after death were pale; there was no sign of congestion in any organ; the blood retained its red color, but did not coagulate quickly; cadaveric rigidity set in within two or three hours. During recovery from protracted narcotism an animal would sometimes be quite conscious, although insensible to pain. Herapath made experiments which proved that the gas which is the active agent in producing the preceding phenomena is carbonic oxide, and his conclusion, confirmed by Snow, was accepted by Dr. Richardson.

No practical application has been made of this curious discovery.

In 1869, Dr. Porcher stated, concerning this mushroom, that it is found in abundance near Charleston, S. C., particularly where the cattle are driven to graze. It is used sliced and fried in butter, or stewed in milk like the common mushroom. A correspondent wrote to him, "I and a number of others have made several meals on *lycoperdon*, and I think I have discovered in myself well-marked evidences of its narcotic influence, and two other experimenters have described similar sensations to me." A case is also referred to in which a person "had been seriously affected in this way by too large a meal of lycoperdon."

The powder of this fungus has been used as a *hæmostatic* in slight and superficial wounds, and, like other dry absorbing powders, in *intertrigo.*

The *tuckahoe* is said to be used as food by the Indians.

LYCOPODIUM, *U. S.*—Lycopodium.

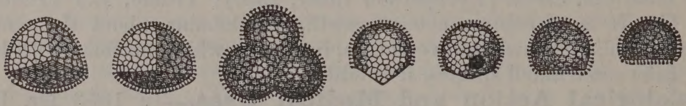
Semen lycopodii, Pulvis lycopodii, Sulphur vegetabile.—Lycopode, Soufre végétal, Fr.; *Bärlappsamen, Streupulver, Hexenmehl,* G.

The sporules of Lycopodium clavatum, *Lin.*, and of other species of Lycopodium.

Nat. Ord.—Lycopodiaceæ.

Origin.—The common *club-moss* is a low creeping perennial, which is found in dry woods distributed over the greater portion of the globe, but is most frequent in northern countries. The stem is two to four feet long, with evergreen imbricated linear awl-shaped inflexed leaves, and with ascending very leafy branches, the fertile ones terminated by a long peduncle bearing two or three erect linear-cylindrical spikes, with roundish ovate bristly pointed bracts, in the axils of which are kidney-shaped sporangia containing the sporules. The spikes are collected before they are fully matured, and after the powder has fallen out, it is separated by a sieve from the other parts. It is collected in Germany and other countries of Central Europe.

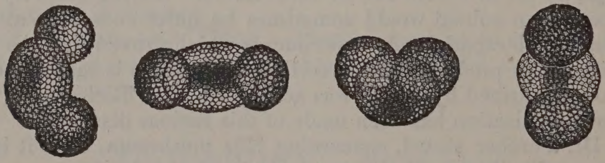
Fig. 102.



Sporules of Lycopodium.

Description.—Lycopodium is a fine, very mobile, pale-yellowish powder which is free from odor and taste. It floats upon water and is wetted by it with difficulty and only after continued trituration, unless it has been previously washed with alcohol, ether, or chloroform, to remove a superficial layer of oily matter; after which it sinks in water. When triturated it acquires a darker tint, becomes more coherent and greasy; when slowly heated, it burns quietly, but when thrown into a flame, it burns suddenly and with a hissing noise. Examined by the microscope it is found to be rounded on one side, while the other forms a short three-sided pyramid. The entire surface is covered by fine polyhedric meshes, and at the intersection of the ridges by small projections.

Fig. 103.



Pollen of Pine.

Constituents.—Flückiger (1872) determined the presence in lycopodium of a much larger amount of fixed oil than 6 per cent. observed by Buchholz (1807), and after rupturing the granules by long trituration with sand, obtained 47 per cent. of a bland oil which does not solidify at —15° C. (5° F.). Buchholz found also in it 3 per cent. of sugar. Stenhouse obtained small quantities of volatile bases, and Flückiger determined the ash to amount to 4 per cent., to be not alkaline, and to contain alumina and 1 per cent. of phosphoric acid.

Impurities and Adulterations.—The sporules of allied species of Lycopodium, particularly of *L. complanatum, annotinum* and *innundatum,* Lin., which are found in both hemispheres, are sometimes collected; they are very similar in appearance and properties. Mineral substances like powdered *talc*, *gypsum*, etc., are detected by the larger amount of ash, and will readily subside when a little is agitated with carbon bisulphide. *Starch* is separated in the same manner, and sublimed *sulphur*, if present, will be dissolved by the liquid and afterwards obtained on evaporating it. Starch is also recognized by the blue color it acquires with solution of iodine. All admixtures are, however, easily detected by means of the microscope; the pollen of pine, which is sometimes found mixed with it, consists of an oval plano-convex cell, at each end of which is a smaller globular one projecting on the flat side.

Medical Uses.—This powder, on account of its extreme lightness and dryness, is used as a convenient protective for tender and raw surfaces of the skin, in *intertrigo*, *erysipelas*, *eczema*, *herpes*, etc., and by druggists to place in boxes containing pills to prevent their adhering to one another.

LYCOPUS, *U. S.*—BUGLEWEED.

Herbe de lycope de Virginie, Fr.; *Virginischer Wolfsfuss*, *G.*

The herb of Lycopus virginicus, *Lin.* *Nat. Ord.*—Labiatæ, Satureieæ.

Origin.—Bugleweed is a perennial herb, growing in woods and shady, moist places in Canada and the United States, southward to South Carolina. It flowers from July to September.

Description.—The stem is nearly smooth, about 12 to 18 inches high, obtusely quadrangular, and with slender runners at the base; the leaves are opposite, short, petioled, elliptic-lanceolate, toothed, wedge-shaped, and entire at the base, and glandular punctate beneath; the flowers are small, in axillary clusters, purplish, and have a calyx with four ovate and bluntish, but pointless teeth. The herb has a somewhat mint-like odor, and an aromatic and bitter taste.

Constituents.—The plant has most likely the general constituents of the labiatæ, prominent among which is volatile oil, some resin, and a little tannin; in this case, perhaps, also a bitter principle. We know of no analysis of the plant.

LYCOPUS EUROPÆUS, *Lin.*; Water horehound, *E.*; Lycope d'Europe, *Fr.*; Wasserandorn, *G.*, has been used in Europe as *Herba marrubii aquatici*. It is indigenous to Europe and North America, and resembles the bugleweed, being mainly distinguished by the often taller, sharply four-angled stem, the more deeply toothed, at the base often pinnatifid leaves, and the five triangular, sharp-pointed calyx teeth. It varies somewhat in its foliage, and is not unfrequently collected with the preceding.

Medical Action and Uses.—Bugleweed is reputed to be astringent and sedative, to reduce the frequency of the pulse, to arrest hemorrhage from the lungs, to allay coughing, and to be a mild narcotic. It has been compared with digitalis. As more than half a century has elapsed since such virtues were first ascribed to it, and it still continues to be neglected and generally unknown, it may be inferred that its supposed powers were in great part imaginary. It is used in an infusion made with half an ounce of the herb in a pint of boiling water. This quantity may be taken in a day.

LYTHRUM.—LOOSESTRIFE.

Herba salicariæ.—Purple willowherb, E.; *Salicaire*, Fr.; *Weiderich*, G.

Lythrum salicaria, *Lin.* *Nat. Ord.*—Lythraceæ.

Origin.—The loosestrife is a perennial herb growing in moist places in the New England States, in Europe and Northern Asia, and is sometimes cultivated in gardens. It flowers in July and August.

Description.—The stem is angular, 3 to 6 feet high. The leaves are opposite, or whorled in threes; lanceolate, sessile, clasping with the heart-shaped base, roughish downy on the lower side, about 3 inches long. The flowers are rather large, in axillary cymes, apparently whorled, form a long, interrupted, wand-like spike, and have 6 purple or sometimes whitish petals and 12 stamens. The herb has a mucilaginous, astringent taste. The blackish-brown, branching, and fibrous root is likewise astringent.

Constituents.—Loosestrife appears to contain mucilage and tannin as its principal constituents.

Medical Action and Uses.—Loosestrife unites in itself demulcent and astringent qualities. It has been much used in Europe in diarrhœa, dysentery, leucorrhœa, blenorrhœa, and passive hemorrhages. It is generally given in a decoction prepared by boiling an ounce of the root in a pint of water, and in doses of one or two fluidounces.

MACIS, *U. S.*—MACE.

Arillus myristicæ.—*Macis*, Fr., G.; *Fleur de muscade*, Fr.; *Muskatblüthe*, G.

The arillus of the fruit of Myristica fragrans, *Houttuyn.*

Origin.—See Myristica. When the nutmeg is gathered, the arillus, which envelops the seed, is cut off and dried in the sun, whereby its bright-red color is changed to brownish-orange. With the view of its better preservation it is often sprinkled with sea-water. It is principally obtained from the Banda Islands.

Description.—Mace is about 1½ inch long, smooth, flat, about $\frac{1}{10}$ inch thick at the base, thinner above, longitudinally slit into irregular, narrow, and somewhat branching bands, of a brownish-orange, and nearly dull color, somewhat translucent, and fatty when pressed or scratched. It breaks readily with a short fracture, but cannot be triturated to powder on account of the oil. It has a very agreeable aromatic odor, closely analogous to that of nutmeg, and a warm, aromatic taste. 70,682 pounds of mace were imported during the fiscal year 1876–1877.

Constituents.—The most important constituent appears to be the volatile oil which is present to the amount of about 8 per cent. Schacht (1862) found it to consist mainly of a hydrocarbon $C_{10}H_{16}$, called *macene*, which is related to, and by Koller (1865) even considered identical with, the myristicene of oil of nutmeg. The oxygenated portion of the volatile oil is even less known than the hydrocarbon. Henry (1824) found red fat soluble, and yellow fat insoluble, in alcohol; but the 24.5 per cent. residue obtained by Flückiger (Pharmacographia) with boiling ether, and drying at 100° C. (212° F.), appeared to have consisted solely of resin and semi-resinified volatile oil. The same author obtained with alcohol 1.4 per cent. of uncrystallizable sugar, and, with hot water, 1.8 per cent. of a body which turned blue, and after drying reddish-violet, with iodine, and appears to be intermediate between starch and mucilage.

Adulterations are not likely to be met with, at least not of the unpowdered mace. The mace of the wild nutmeg (*M. fatua*) is of a darker red color, less divided at the base, with more slender bands, and destitute of the grateful fragrance and taste of true mace.

Medical Action and Uses.—The operation of mace appears to be the same as that of nutmeg, and there is reason to believe that an excessive dose of it may induce dangerous narcotism. It is used to impart an aromatic taste to medicines, but more commonly as a condiment for flavoring food and promoting its digestion.

MAGNESIA, *U. S.*, *Br.*—MAGNESIA.

Magnesia usta, P. G.; *Magnesia calcinata.—Calcined magnesia*, E.; *Magnésie*, *Magnésie calcinée*, Fr.; *Gebrannte Magnesia*, G.

Formula MgO. Molecular weight 40.

Preparation.—Take of Carbonate of Magnesium a convenient quantity. Put it into an earthen vessel, and expose it to a red heat for two hours, or until the carbonic acid is entirely expelled, rubbing it constantly with an iron spoon during calcination. *U. S.*

Take of Carbonate of Magnesia four ounces. Put it into a Cornish or Hessian crucible closed loosely by a lid, and expose it to a low red heat until a small quantity taken from the centre of the crucible, when it has cooled, and dropped into diluted sulphuric acid, causes no effervescence. *Br.*

The British Pharmacopœia recognizes two varieties of magnesia, the heavy, made from the heavy magnesium carbonate by the process just given, and *Magnesia levis* or *light magnesia*, which is made in precisely the same manner from the light magnesium carbonate. In the United States both kinds are extensively used, but when the heavy variety is desired, it is usually designated in prescriptions as *Magnesia ponderosa*.

The officinal carbonate of magnesium consists of magnesium carbonate and hydrate. On heating it water and carbonic acid are given off, and magnesium oxide remains behind: $3(MgCO_3).Mg2HO.3H_2O$ yields $4MgO + 3CO_2 + 4H_2O$. The carbonate of magnesium is pressed somewhat firmly into a crucible, and this is placed in a suitable furnace, loosely covered with a lid, to prevent the product from becoming contaminated with ashes and other impurities, and then heated to dull redness. The expulsion of the water and carbonic acid gas keeps the surface of the powder continually in motion, and there is no necessity of testing it as long as that motion is kept up; when the motion ceases, a small quantity of the powder is taken from beneath the surface and near the centre, mixed with sufficient water to displace the air, and then poured into an excess of dilute sulphuric acid. If no evolution of carbonic acid gas takes place, the product is finished, and may be dipped out with a ladle, and the crucible filled with a fresh portion of magnesium carbonate without removing it from the furnace. Made by the process detailed in the U. S. Pharmacopœia, a large and rather flat earthen vessel should be used, to allow of the magnesia being stirred continuously, in which case the heat may be raised to full redness; but it should never be raised to that degree if the stirring is omitted, because the magnesia would become dense and granular, and with difficulty soluble in dilute acids. The yield is between 40 and 43 per cent. of the weight of the magnesium carbonate.

Properties.—The two varieties of magnesia have the same composition and chemical properties, and differ from each other only in the degree of aggregation of their molecules. Heavy magnesia is more readily miscible with water than the light kind, and, like the latter, should remain suspended in the water for some time, and settle gradually. Should it subside very rapidly, the probability is that it was exposed to too high a degree of heat. Magnesia is a white powder, without odor, and of an earthy, but destitute of saline taste. Exposed to a high heat, it becomes more compact, but does not fuse except before the oxyhydrogen blowpipe. According to Fresenius, it requires 55,000 parts of water for solution; but the liquid has a distinct alkaline reaction. Its specific gravity varies between 2.3 and 3.3. When mixed with water it unites with it, forming a hydrate, having the composition Mg2HO, and, when heated, losing 31 per cent. of its weight. Exposed to the atmosphere a similar change takes place, but carbonic acid is also absorbed, and a corresponding quantity of oxycarbonate is formed. It should, therefore, be preserved in well-stoppered bottles.

Tests.—The degree of hydration allowable is not given by the Pharmacopœias; but when well kept the loss by heating to redness should not exceed five or six per cent. It should dissolve in dilute acid without any or with but very slight effervescence. When treated with dilute nitric acid it should dissolve without leaving any residue, and the solution should yield no precipitates with barium nitrate (*sulphates*) or silver nitrate (*chlorides*), and potassium ferrocyanide should impart only a bluish tint, but not a deep blue precipitate (iron). On adding ammonium chloride and an excess of ammonia, the solution remains clear on the further addition of ammonium oxalate (absence of *calcium*), and on the addition of sulphydrate of ammonium (*zinc*, etc.); but yields with phosphate of sodium a white precipitate of ammonio-magnesium phosphate.

Several proprietary articles, consisting of heavy magnesia, are occasionally met with; this magnesia is generally characterized by freedom from grittiness and ready miscibility with water; but is not superior to a dense magnesia obtainable by careful manipulation from a properly prepared magnesium carbonate.

The metal *magnesium* is widely distributed, but is less abundant than calcium; it is found as silicates in *meerschaum*, *olivine*, *mica*, *serpentine*, and other minerals; as chloride in sea-water and the waters of saline springs, and as carbonate in *magnesite* and in *dolomite* or magnesian limestone. The metal is obtained by heating sodium with anhydrous magnesium chloride; the resulting sodium chloride is dissolved by water, and the magnesium left behind in the form of a gray powder, which is fused and moulded as desired. It is a silver-white metal, of a strong metallic lustre, malleable, fusing at a red, and volatilizing at a white heat, but burning with a bright white light when held in the flame of a gas jet. Its density is only 1.78; it is not altered in dry air, and but slightly tarnished in a damp atmosphere. *Soapstone* or *French chalk* is a double silicate of magnesium and aluminium.

Off. Prep.—Pilulæ copaibæ, *U. S.;* Pulvis rhei comp., *U. S., Br.;* Trochisci magnesiæ, *U. S.*

Medical Action and Uses.—The action of magnesia and of its carbonates consists partly in neutralizing the acid in the alimentary canal, and partly in rendering acid secretions, as the urine, either neutral or alkaline. If a sufficient quantity of acid exists in the stomach, or is attracted thither by the magnesia, a neutral purgative salt is formed; but in default of such a combination the magnesia may pass into the intestine unchanged in part, and if it be taken habitually, may accumulate there and form concretions large enough to obstruct the bowel.

Magnesia has the advantage over other laxatives in being almost tasteless, and in rarely causing nausea or colic. It produces feculent rather than watery stools, which are remarkable for their slight degree of fetor. It is slower than salines in its operation, but quite as thorough. Its use is most distinctly indicated in whatever condition is attended with gastro-intestinal acidity, with *heart-burn*, *sour eructations*, and *flatulence*. It has even arrested the *vomiting of pregnancy* when the liquid rejected was acid. Although it corrects gastric acidity, it does not remove the cause of this symptom, for which purpose aromatics and bitter tonics are usually required. It is ordinarily associated with rhubarb in the treatment of dyspeptic *diarrhœa*, especially in children; and is a very appropriate laxative in *hemorrhoidal* cases attended with constipation. It is useful in the *aphthous* affections of the mouth which attend infantile diarrhœa. In *gout* and its allied disorders its antacid qualities render it appropriate; the following formula is commonly employed: ℞. Magnesii sulph., ℥j–ij; Aquæ menthæ virid., f℥x; Vin. colchici seminis, Syrup. simpl., āā f℥j; Magnesiæ, ʒij.—M. S.—From one to three tablespoonfuls every two hours until from four to six stools are produced in the twenty-four hours. In infantile *colic* the following carminative mixture is used: ℞. Magnesiæ, gr. xxx; Tinct. assafœtidæ, gtt. xl; Tinct. opii, gr. xx; Sacch. alb., gr. lx; Aquæ, f℥j.—M. S.—Twenty drops and upwards every hour until relief occurs. Magnesia is appropriate, as already stated, in cases of *uric acid gravel*, but is probably less so than the carbonates of sodium and potassium; but in such cases, when marked by gastric acidity, it should not be neglected.

As an antidote to *arsenious acid* freshly precipitated magnesia ranks next in value to freshly prepared sesquioxide of iron. It is also antidotal to *acids*, including oxalic acid, and to *phosphorus*. In all cases of poisoning for which it is appropriate, magnesia should be very largely administered, diffused in water.

As a purgative, the *dose* of magnesia is about forty grains, and five grains for infants. As an antacid it may be taken in doses of ten grains after meals, suspended in water. Mixture with milk, which is usual to disguise its taste, renders its operation slower.

MAGNESII ACETAS.—Acetate of Magnesium.

Acétate de magnésie, Fr.; *Essigsaure Bittererde*, G.

Formula $Mg2C_2H_3O_2$. Molecular weight 142.

Preparation.—One hundred and twenty parts of carbonate of magnesium are dissolved in sufficient acetic acid, and the filtered solution evaporated until three hundred parts remain.

Properties.—When entirely exsiccated, it has the formula given above; but, being deliquescent and uncrystallizable, it is difficult to remove all the water. It is gum-like in appearance, freely soluble in water and alcohol, and has a bitterish taste, less pleasant than magnesium citrate. Prepared as above, is is a syrupy liquid, the taste of which may be improved by syrup of orange peel.

Medical Action and Uses.—This salt was introduced as a substitute for citrate of magnesium, probably on account of its greater cheapness, it being assumed to possess the same mode of action as the citrate. A committee of the Pharmaceutical Society of Paris reported it to be a purgative, whose slight taste and great solubility recommended it. It does not, however, seem to have been approved by physicians.

MAGNESII CARBONAS, *U. S.*—Carbonate of Magnesium.

Magnesiæ carbonas, Br.; *Magnesia carbonica*, P. G.; *Magnesia alba*, *Magnesia hydrico-carbonica*, *Carbonas magnesicus*.—*Carbonate of magnesia*, E.; *Carbonate de magnésie*, *Magnésie blanche*, Fr.; *Weisse Magnesia*, G.

Formula $(MgCO_3)_3.MgO.4H_2O$, or $3MgCO_3.Mg2HO.3H_2O$. Molecular weight 364.

Preparation.—Take of Sulphate of Magnesia ten ounces; Carbonate of Soda twelve ounces; Boiling Distilled Water a sufficiency. Dissolve the sulphate of magnesia and the carbonate of soda each in a pint of the water, mix the two solutions, and evaporate the whole to perfect dryness, by means of a sand-bath. Digest the residue for half an hour with two pints of the water, and having collected the insoluble matter on a calico filter, wash it repeatedly with distilled water until the washings cease to give a precipitate with chloride of barium. Finally, dry the product at a temperature not exceeding 212° F. *Br.*

The above process yields *heavy* magnesium carbonate; if the two solutions are mixed, and then boiled for 10 or 15 minutes, but not evaporated, the precipitate will be more bulky, and, after washing and drying, constitutes the *Magnesiæ carbonas levis* or *light carbonate of magnesia* of the British Pharmacopœia.

On mixing cold solutions of magnesium sulphate and sodium carbonate, a white voluminous precipitate takes place, which, in the course of several days, is gradually converted into the compound $MgCO_3.3H_2O$, identical with that which often crystallizes from the effervescing solution of magnesia (see p. 839), but, when heat is applied, carbonic acid is given off, and the insoluble portion remaining is a hydrato-carbonate, the composition of which varies somewhat, a larger amount of carbonic acid being given off, if the heat be continued, and the heavy magnesium carbonate obtained, as described above, has probably the formula determined by Berzelius, $3MgCO_3.MgH_2O_2.3H_2O$, which compound, on ignition, would yield nearly 44 per cent. of magnesia, MgO, as required by the British Pharmacopœia. Light magnesium carbonate yields less (between 40.3 and 41.7 per cent.) magnesia, according to Otto and Laake. The formula $3MgOCO_3.MgH_2O_2.4H_2O$ requires 41.9 per cent. MgO. A compound of the composition $4MgOCO_3.MgH_2O_2.5H_2O$ would yield 41.3, and with an additional H_2O only 40 per cent. MgO.

Properties.—Besides the slight difference in composition just referred to, the heavy and light magnesium carbonates differ only in the degree of aggregation of their molecules, the former being slightly granular, the latter a smooth and less dense powder, both being inodorous and of a slight earthy taste. It is almost insoluble in water, requiring, according to Fyfe, 2500 parts of cold and 9000 parts of boiling water for solution, and when it is moistened with water and applied to turmeric-paper, a brown color is gradually produced. When heated to dull redness, water and carbonic acid gas are given off and magnesia remains. It dissolves with effervescence in dilute sulphuric, muriatic, and other acids, and the solutions have the chemical behavior of magnesium salts.

Tests.—Magnesium carbonate may be obtained from the mother-liquors or bittern of salt-works, and is prepared on an extensive scale in England from magnesian limestone, by treating it in the state of powder with cold water and carbonic acid, under a pressure of 5 or 6 atmospheres; magnesium bicarbonate is first dissolved, removed from the calcium salt, and, by boiling, converted into the officinal carbonate. From both these sources the magnesium carbonate may be contaminated with calcium compound; and from the former source, by incomplete washing, also with the acidulous radicals contained in the mother-liquor, more particularly with chlorides, bromides, and sulphates. These impurities are detected by dissolving the carbonate in dilute nitric acid, and this solution should not be precipitated by nitrate of silver (*chloride* and *bromide*), or barium nitrate (*sulphate*); neutralized with ammonia, it should not be precipitated by ammonium oxalate (*calcium*). On the addition of ammonia in excess, a white precipitate is produced, which is completely soluble in ammonium chloride (an insoluble portion would indicate *alumina*), and the ammoniacal solution does not yield a white precipitate with hydrogen sulphide (*zinc*). Traces of iron are usually present, and are unobjectionable.

Off. Prep.—Liquor magnes. carbon., *Br.;* Liq. magnes. citrat., Magnesia, *U. S.*, *Br.;* Trochisci bismuthi, *Br.*

Medical Uses.—The carbonate is less efficient than magnesia itself, but its action and uses are the same. It is said to remove *warts* from the skin when taken night and morning in teaspoonful doses, and continued for several weeks.

Carbonate of magnesium may be given as a laxative in doses of from 30 to 120 grains; as an antacid, from five to twenty grains may be taken after meals. It may be agreeably administered in carbonic acid water.

MAGNESII SULPHAS, *U. S.*—SULPHATE OF MAGNESIUM.

Magnesiæ sulphas, Br.; *Magnesia sulfurica*, P. G.; *Sal amarum*, *Sal Epsomense*, *Sal anglicum*, *Sal Sedlicense*, *Sulfas magnesicus*.—*Sulphate of magnesia*, *Epsom salt*, E.; *Sulfate de magnésie*, *Sel d'Epsom*, *Sel de Sedlitz*, *Sel amer*, Fr.; *Bittersalz*, *Schwefelsaure Magnesia*, G.

Formula $MgSO_4.7H_2O$. Molecular weight 246.

Origin and Preparation.—Sulphate of magnesium is contained in sea-water, and in the waters of many mineral springs, which thereby acquire a bitter taste. The *Crab Orchard salt* of Kentucky is the same salt in an impure state, and, as analyzed by J. T. Viley (1871), contains about 65 per cent. of magnesium sulphate after having been dried at 120° C. It probably results from the mutual decomposition of gypsum and magnesian limestone, and is obtained by evaporating the water which collects in wells dug in the ground. The pure salt is made on the large scale from *magnesite*, which is principally $MgCO_3$, by dissolving it in dilute sulphuric acid, and crystallizing. Large quantities are made by various processes from magnesian limestone, and more recently it is extensively obtained at the Stassfurt salt works, principally from the mineral *kieserite*, which is $MgSO_4$ combined with varying quantities of water, and in its natural state as insoluble as gypsum.

Properties.—As found in the market, magnesium sulphate has generally been purified by resolution in water and rapid crystallization, and forms small rhombic prisms, which resemble those of oxalic acid and sulphate of zinc, are perfectly transparent, without odor, but have a cooling and bitter saline taste. It dissolves at the ordinary temperature in about $1\frac{1}{2}$ times its weight, and on boiling in less than its own weight of water; it is also soluble in diluted alcohol, but sparingly so in strong alcohol. Exposed to air the crystals slowly effloresce, becoming superficially opaque; when heated the salt melts, gives off $6H_2O$, and at a still higher temperature parts with the last molecule of water, fuses, and on cooling congeals into a white mass. The total weight of water amounts to 51.22 per cent.

Tests.—The aqueous solution yields a white precipitate of barium sulphate on the addition of barium chloride. It is not precipitated in the cold by potassium bicarbonate or ammonium carbonate, but gives white precipitates with the carbonates and the hydrates of sodium and potassium, which are redissolved by ammonium chloride. Ammonia added to its solution likewise causes a white precipitate soluble in ammonium chloride, and this solution, on the addition of ammonium phosphate, deposits all magnesium in the form of a crystalline powder, which is phosphate of magnesium and ammonium, $MgNH_4PO_4.6H_2O$. The filtrate from it, evaporated to dryness and ignited, should leave no residue, or only a slight one consisting of phosphoric acid, in which potassium or sodium compounds should not be indicated by the proper tests.

Impurities are detected in precisely the same manner as in the nitric acid solution of magnesium carbonate (see page 872).

Pharmaceutical Uses.—Sulphate of magnesium is used for preparing Magnes. carbonas and Liquor magnes. carbon., and forms a constituent of Enema magnes. sulphat. and Mistura sennæ comp., *Br*.

Medical Action and Uses.—Sulphate of magnesium, dissolved in a large quantity of water and taken on an empty stomach, is very prompt in its operation, producing copious watery dejections and generally diuresis. Indeed, if the skin be kept cool, the latter mode of operation may exceed the purgative effect, particularly if the dose be not large. Delicate persons, especially in cool weather, are apt to feel chilly and weak during its operation. This refrigerant influence renders it appropriate in warm weather and in febrile affections. If the dose be excessive and largely diluted, hypercatharsis may occur. On the other hand, large doses not thus diluted have sometimes occasioned an alarming sedation, with pallor, debility, coldness, and even syncope, although no purgation whatever occurred. In at least one case, that of a boy ten years old, death resulted. These effects, according to the dose and degree of dilution with water, are more or less applicable to all saline cathartics.

When properly administered it is nearly always a safe and harmless purgative; indeed, it is generally used without medical advice by persons affected with *constipation*, slight *febrile attacks*, etc. It is highly objectionable when habitually employed for the former purpose in a full purgative dose, for it soon ceases to act purgatively, and confirms the evil it was used to cure. It is also one of the least eligible cathartics in cold weather. On the other hand, if used in small doses largely diluted, as a drachm in half a pint of water, it may be continued for a long time without sensibly diminishing in activity. As an antiphlogistic purgative at the commencement of *fevers*, especially of malarial fevers, it is justly esteemed, whether or not it is preceded by a dose of eight or ten grains of calomel, which many think essential to the result. In *typhoid fever*, there is much reason to believe that a gentle purgative action maintained during the first week of the attack by this medicine tends to moderate the fever, mitigate the special typhoid phenomena of the disease, and lessen the danger of intestinal perforation. In *dysentery* of a sthenic type, saline laxatives, and this one among the number, have a decided influence in lessening the tormina, tenesmus, and bloody and mucous stools, and reducing the febrile action. But to be efficient its administration ought to commence as early as possible in the disease, and before ulcers form in the rectum. In both of the last-mentioned affections an ounce of the salt may be dissolved in a pint of water, and a wineglassful of the solution administered every two or three hours. When this treatment has been pursued for twenty-four or forty-eight hours, it should be suspended for about twelve hours, and then resumed. In various inflammations, serous and parenchymatous, it was formerly the custom to administer Epsom salt in small doses, largely diluted, and with the addition of half a grain of tartar emetic to each pint of the solution, which was given in wineglassful doses at intervals of three hours. The method is temporarily supplanted by the use of medicines which reduce the pulse-rate and temperature without providing any outlet for the effete products of morbid action.

In all cases of *intestinal obstruction* not clearly due to organic causes, the use of this or some similar medicine should have a fair trial, care being taken to employ a weak solution and to administer it in moderate doses at proper intervals. In *painters' colic*, sulphate of magnesium with the addition of sulphuric acid has been regarded as a specific for the disease, but erroneously.

Administration.—From half an ounce to an ounce of Epsom salt dissolved in half a pint of water is a full purgative dose; but even a less proportion of the salt and a larger proportion of water will produce nearly an equal effect. Its taste may be partially disguised by aromatic sulphuric acid in the proportion of half a fluidrachm to the half pint of liquid. The addition to the saline solution of a little strong coffee helps to mask its nauseous flavor. It is frequently given in an infusion of senna when a prompt and vigorous operation is required. This mixture forms the basis of the so-called "black draught."

MAGNOLIA, *U. S.*—MAGNOLIA.

Magnolia bark, E.; *Écorce de magnolier*, Fr.; *Magnolienrinde*, G.

The bark of Magnolia glauca, *Lin.*, Magnolia acuminata, *Lin.*, and Magnolia tripetala, *Lin.* (M. umbrella, *Lam.*).

Nat. Ord.—Magnoliaceæ.

Origin.—*M. glauca*, *sweet bay*, *white bay*, *beaver tree*, or *swamp sassafras*, is indigenous to swampy localities near the coast of the United States from

Massachusetts to Louisiana; in the northern part of the country it is shrubby; further south it is a small tree 15 to 25 feet high. It has oval oblong leaves which are shining above and white beneath, and bears fragrant white flowers about 2 inches in diameter, with about 10 ovate or obovate obtuse petals. The leaves may be used for marking by placing the white surface upon the fabric and writing with some pressure upon the upper surface.

M. acuminata, called *cucumber tree* from the appearance of the young fruit, is found in groves and rich woods from Western New York to Ohio and southward, chiefly along the Alleghenies to Georgia. It grows to the height of 60 to 80 or 90 feet, and has oblong acuminate, underneath pubescent leaves, and light bluish-green flowers tinged with yellow, about 4 or 5 inches in diameter.

M. umbrella, *umbrella tree*, so called from the large leaves appearing whorled at the ends of the branches, is found in rich soil from Pennsylvania and Ohio southward along the Alleghenies. Its leaves are 2 to 3 feet long, obovate lanceolate, pointed at both ends, silky when young, and its white flowers are about 7 inches in diameter.

The magnolias produce their flowers in May and June; they have a white or greenish calyx of 3 sepals, many stamens with short filaments, and many ovaries collected on an elongated receptacle, forming a cone-like aggregation of fruits which open at maturity, the berry-like seeds being suspended by a thread-like funiculus.

Description.—The bark necessarily varies as obtained from the different species. The young bark of M. glauca is light orange-brown, glossy, with some gray spots, and underneath the thin corky layer of a green color. The bark of the larger branches is nearly smooth, externally of a light-gray or whitish color, marked with scattered warts and some longitudinal cracks. Older bark has the warts somewhat confluent, and the cracks deepened into fissures. The inner surface is whitish, or, after drying, yellowish or pale-brownish, smooth, and very finely and closely striate. The bark of M. tripetala is thicker, is of a pale brown underneath the ash-gray layer, and has a thick liber with rather tough bast fibres. Magnolia bark breaks with a more or less fibrous fracture in the bast layer, and exhibits upon the light-brownish transverse section rather broad wedges of the bast and medullary rays. The dried bark has scarcely any odor, but its taste is warm, spicy, and bitter, particularly in the young bark.

Constituents. — The bark of *magnolia grandiflora* was examined by Stephen Procter (1842), who found in it a little volatile oil, resin, and a crystalline principle resembling liriodendrin. The root and stem-bark of M. glauca were investigated by W. D. Harrison (1862), the former yielding a little volatile oil and nearly tasteless and colorless crystals; the latter contained tannin, producing a dark green precipitate with ferric salts, but did not yield the crystalline principle, nor could the bitter principle be isolated. By treating the alcoholic extract of the fruit of M. umbrella with hot petroleum benzin, Wallace Procter (1872) obtained colorless crystals of *magnolin*, which are soluble in alkalies, alcohol, ether, chloroform, carbon bisulphide, and fixed oils, but sparingly so in boiling water, in which they fuse; the solutions have an irritating taste. The crystals are colored red by sulphuric acid, and brown by nitric acid. The pungent taste of the fruit is due to a soft resin, and the odor to a little volatile oil.

Medical Uses.—The bark of the several medicinal species of magnolia is bitter and aromatic without astringency. Like numerous other plants of similar qualities it has been used in hot decoction to produce diaphoresis in fevers, bronchial *catarrhs*, *rheumatism*, and *gout*, and in cold decoction or tincture as a tonic. The tree is said to render clear waters near which it grows, and to prevent malarial affections. The preparations of the bark spoken of above are used in the cure of intermittent fevers. The *dose* of the recently dried bark in powder is stated to be from thirty to sixty grains, frequently repeated. The infusion or decoction is less eligible than the tincture, which is not, however, officinal.

MALTUM HORDEI.—BARLEY MALT.

Malt d'orge, *Drêche*, Fr.; *Gerstenmalz*, G.

Preparation and Properties.—Different kinds of grain may be employed for the preparation of malt; but the kind most generally used is barley. The grain is soaked in water, and then placed in heaps; heat is spontaneously generated, and, by occasional turning, prevented from rising too high. Under these conditions, germination takes place, and when the germ has acquired the desired length, the grain is rapidly dried, and constitutes *malt*. According to the degree of heat employed in drying, the color of the malt varies somewhat, and is known as either *pale*, *pale amber*, *amber*, or *amber-brown*. For some purposes, malt is made to undergo a roasting process in revolving cylinders, to obtain *roasted* or *black* malt, if the integuments are of a dark-brown color; or *crystallized* malt, if the interior of the grain has assumed that color. Malt has an agreeable odor and a sweet taste, and yields with water a more or less deep yellowish-brown or brown infusion.

Constituents.—The chemical changes taking place in germinating grain and sprouting potatoes were explained by Payen and Persoz (1833), who discovered a peculiar ferment *diastase*, which exists in the vicinity of the embryo, but not in the radicle of the germ; on making an infusion of fresh malt, precipitating salts and some proteids with a little alcohol, and then adding more alcohol, diastase, in an approximately pure condition, is precipitated; but, according to Dubrunfaut (1868), is a mixture which contains the true fermentative principle *maltin*. The remaining constituents of malt are those of barley, with the exception of *dextrin* (see page 170), and *sugar*, which have been formed from a portion of the starch, the remainder of which, still present in the malt, is likewise converted into the same compounds by the process of *mashing*, which consists in preparing an infusion of ground malt, called *wort*, and keeping it at a temperature of about 70° C. (158° F.).

During the process of malting, good barley increases about 9 per cent. in volume, but loses about 20 per cent. in weight; and good malt should yield to water soluble principles amounting to two-thirds of its weight. Diastase has the property of converting starch into dextrin and sugar, and in this respect resembles *ptyalin*, a ferment met with in the salivary glands of animals. Coutaret (1870) regards the two ferments as being identical.

Pharmaceutical Uses.—EXTRACTUM MALTI; Extract of malt, *E.;* Essence de malt, *Fr.;* Malzextract, *G.*—One part of ground barley malt is macerated for three hours with its own weight of water; 4 parts of water are then added, and the whole digested for an hour at 65° C. (149° F.), heated to the boiling point, and at once expressed and strained. The clear liquid is rapidly evaporated to the consistence of a thick extract (*P. G.*). As found in the market extract of malt usually has the consistence of a thick syrup, a yellowish-brown color, and the sweet taste of malt. It is serviceable in emulsionizing fixed oil, and as a vehicle for various medicaments.

EXTRACTUM MALTI FERRATUM, *P. G.*, is made by dissolving 2 parts of pyrophosphate of iron in 3 parts of water, and incorporating the solution with 95 parts of extract of malt. Hager (1876) recommends instead the use of 3 parts of saccharated iron (see page 627), rubbed up with 7 of glycerin and 90 of extract of malt.

If quinia is combined with malt, the neutral tannate of quinia is best employed. Hops may be used with it in the form of fluid extract of lupulin. A combination with pepsin should be made extemporaneously, since the taste is gradually modified.

Medical Action and Uses.—Liquid and semifluid extracts of malt were much used a few years ago in Germany, where they were first introduced, as tonic and nutritious substitutes for malt liquors. Thence they were diffused to every part of the world, until their local manufacture displaced the imported preparations, and both were superseded by some later fashionable medicine. In many cases they were found quite beneficial in states of chronic debility due to organic disease or infirmity, or to mere nervous exhaustion, but seldom more, and often less so, than good malt liquors into the composition of which hops enter. The semiliquid preparation, which is the only true extract of malt, is very difficult to take, owing to its tenacious and adhesive qualities, and is generally prescribed in teaspoonful doses mixed with soup, wine, beer, or milk.

MANGANESII OXIDUM NIGRUM, *U. S.*—BLACK OXIDE OF MANGANESE.

Manganum hyperoxydatum, P. G.; *Oxydum manganicum, Magnesia vitriariorum (vel nigrum).—Peroxide of manganese, Pryolusite*, E.; *Oxyde (peroxyde) de manganèse*, Fr.; *Braunstein*, G.

Formula MnO_2. Molecular weight 87.

Origin.—Pyrolusite, or, as it is commercially called, *black manganese* or *manganese*, is found in different parts of Germany, France, Spain, and Great Britain, and also in Nova Scotia, Vermont, Pennsylvania, and other parts of North America. Sometimes it is found nearly pure, but it is generally associated with other manganic ores, and often with iron, lime, baryta, silica, etc.

Properties.—It is amorphous, and is then of a dull gray-black color, or in masses composed of tabular, fibrous or radiating crystals, having a bright metallic lustre, and yielding a black powder. Its specific gravity is 4.8 to 4.94. It may also be obtained artificially by carefully fusing manganous carbonate with potassium chlorate, and washing the mass. It is insoluble in water and in weak acids; it dissolves in hydrochloric acid to manganous chloride, while chlorine is given off; $MnO_2 + 4HCl$ yields $MnCl_2 + 2H_2O + Cl_2$. When it is treated with sulphuric acid in the presence of oxalic acid, the latter is oxidized to carbonic acid, manganous sulphate being dissolved; $MnO_2 + H_2SO_4 + H_2C_2O_4$ yields $2CO_2 + MnSO_4 + 2H_2O$. When heated to redness, the black oxide parts with a portion of its oxygen, leaving brown manganic oxide, Mn_2O_3, or, at a bright red heat, red manganoso-manganic oxide, $MnO.Mn_2O_3$.

Valuation.—The value of black oxide of manganese for the production of chlorine may be determined in various ways, either by ascertaining directly the loss in weight occasioned by the evolution of carbonic acid gas in the reaction just described, when the weight of $2CO_2$ (88) will indicate 1 molecule of MnO_2 (87); or after the reaction has been completed, the excess of the oxalic acid added is estimated by a standardized solution of potassium permanganate, which is added until it ceases to be decolorized. The generation of chlorine and its oxidizing effect upon ferrous salts is utilized for the same purpose in the following manner: 5 grams (or 50 grains) of the finely powdered oxide are mixed in a flask with about 15 grams of water and 45 grams (or 1 ounce) of strong hydrochloric acid; 32 grams (or 320 grains) of pure granular ferrous sulphate are likewise weighed out and added, at first in larger, afterwards in smaller, portions, until, after some digestion, the odor of chlorine has entirely disappeared, and a drop of the liquid is colored blue by ferridcyanide of potassium from the excess of ferrous salt. If the oxide was pure MnO_2, it would require 32 grams (or 320 grains) of the ferrous sulphate; from the exact quantity of the latter used, the percentage of the former is easily calculated. Since the Pharmacopœia requires black manganese to contain at least 66 per cent. of MnO_2, the above quantity, after the addition of 21.1 grams (or 211 grains), should give a blue reaction with the ferridcyanide. The 32 grams (or 320 grains) of the ferrous sulphate may also be added at once, and after the completion of the reaction, its excess ascertained by standardized permanganate of potassium.

Impurities.—The presence of carbonates is detected by the effervescence occurring with *cold* dilute muriatic acid, and the presence of iron is ascertained in the solution obtained with strong or with hot dilute muriatic acid, by the blue precipitate with ferrocyanide of potassium.

Composition.—Black oxide of manganese consists of 63.2 parts (1 atom) of manganium, and 36.8 parts (2 atoms) of oxygen.

The metal *manganium* or *manganesium* may be obtained by reducing one of its oxides with carbon at a very high temperature. It resembles iron, but is rather darker, harder, and more brittle; its specific gravity is 8. Besides the oxygen compounds mentioned above, it unites with this element also in several other proportions. *Manganous oxide*, MnO, is a grayish-green powder, which readily oxidizes in contact with the air. *Manganic acid*, H_2MnO_4, is not known in the free state, but only in the form of salts, which have a green color. *Permanganic acid*, $H_2Mn_2O_8$, is a deep violet-colored liquid, which is a powerful oxidizing agent (see Potassium permanganate).

Uses.—Black oxide of manganese is extensively used for the preparation of chlorine, and the solution obtained in this process may be employed for preparing other compounds of manganium. It is employed in preparing Aqua (liquor) chlorinii, *U. S.*, *Br.;* Hydrarg. perchloridum, Liq. sodæ chloratæ, Potass. chloras, Potass. permanganas, *Br.*

Medical Action and Uses.—Black oxide of manganese was introduced into medicine when its chemical affinities were found to be nearly analogous to those of iron. But the chemical ground of judgment proved, as it usually does, a fallacious one in therapeutics, and none of the curative effects anticipated were secured. On a different ground, probably, it was employed in the treatment of morbid sensibility of the stomach, an affection which was, doubtless, in some cases, gastralgia, and in others simple ulcer. When it was of service in such cases it probably acted as bismuth subcarbonate or subnitrate acts, by furnishing an inert and insoluble coating to the part. It was given in the *dose* of from five to forty grains.

MANGANESII SULPHAS, *U. S.*—SULPHATE OF MANGANESE.

Manganum sulphuricum, *Sulfas manganosus.*—*Manganous sulphate*, E.; *Sulfate de manganèse*, *Sulfate manganeux*, Fr.; *Schwefelsaures Manganoxydul*, G.

Formula $MnSO_4.4H_2O$. Molecular weight 223.

Description.—Black oxide of manganese is mixed with sufficient strong sulphuric acid to obtain a thin magma, which is heated to boiling and evaporated to dryness; the mass is now heated in a crucible to dull redness for some time for the purpose of decomposing the iron sulphate. When cool, it is treated with water, and the solution, if iron be still present, digested with manganous carbonate, then filtered and evaporated to crystallize.

Properties.—When crystallized below 6° C. (43° F.), the salt contains $7H_2O$, and is isomorphous with ferrous sulphate; above that temperature and below 20° C. (68° F.), it contains only $5H_2O$, and has the form of copper sulphate. But the salt usually met with is crystallized between 20° and 30° C. (86° F.), and forms right rhombic prisms, containing $4H_2O$, three of which are given off at a temperature of 115° C. (239° F.). A salt of the same composition as this residue is also obtained by adding sulphuric acid to solution of manganous sulphate and evaporating; it forms a granular powder. The crystals of the officinal salt are of a pale rose-red color, slightly efflorescent in a dry atmosphere, insoluble in alcohol, but freely soluble in water at the ordinary temperature, and somewhat less at the boiling point. The solution has a styptic taste, and yields with ammonium sulphide a flesh-colored precipitate, and with ferrocyanide a white one, but is not disturbed by tannic acid. The fixed alkalies and alkaline carbonates produce white precipitates, which, on exposure to air, are rapidly oxidized, turning brown.

Tests.—The impurities likely to exist are sulphate of iron, the presence of which will cause the precipitate with potassium ferrocyanide to have a blue color; sulphate of copper, which produces a black precipitate by sulphuretted hydrogen; and the sulphates of magnesium and the fixed alkalies, which are indicated by the residue left after precipitating the solution completely with ammonium sulphydrate, evaporating the filtrate to dryness, and igniting.

Other Compounds. MANGANESII CARBONAS.—Carbonate of manganium is prepared by precipitating in the presence of a little syrup a solution of manganous sulphate with carbonate of sodium, washing the precipitate well, and drying it rapidly with a moderate heat. It is a white powder, having a brownish tinge, and dissolving in carbonic acid water, leaving only a slight residue of brown manganic oxide.

MANGANESII CHLORIDUM.—Chloride of manganium is most economically obtained when preparing chlorine from black oxide of manganese and muriatic acid; the resulting liquid is digested with manganous carbonate until the iron has been completely precipitated, the filtrate is evaporated, crystallized, and by recrystallization purified from calcium chloride if present. The salt is in granular, or when slowly evaporated in tabular, crystals of a pale rose-red color, and has the composition $MnCl_2.4H_2O$. It is soluble in alcohol, and requires at ordinary temperature about 2½ parts of water for solution.

MANGANESII IODIDUM.—Manganous iodide is a very deliquescent salt, and is best administered in the form of *syrup*, which may be prepared by dissolving manganous carbonate in hydriodic acid, or by the following formula proposed by Prof. Procter (1850): Take of sulphate of manganese 16 drachms; iodide of potassium 19 drachms; sugar, water, each sufficient. Dissolve each of the salts in three fluidounces of water containing two drachms of syrup; mix, and after precipitation filter the solution into a bottle containing twelve ounces of sugar; add water to make a pint, and shake the bottle till the sugar is dissolved. Each fluidounce contains one drachm of iodide of manganium; it may be given in doses of ten drops to half a fluidrachm.

The same author has also proposed a *syrup of the iodides of iron and manganese*, to be prepared as follows: Take of iodide of potassium 1000 grains; ferrous sulphate 630 grains; sulphate of manganese 210 grains; clean iron filings 100 grains; powdered sugar 4800 grains; distilled water sufficient. Rub the sulphates and iodide separately to powder, mix with the iron filings, add half a fluidounce of water, and rub to a uniform paste; add the same quantity of water a second and a third time, at intervals of fifteen minutes, and rub. Place the sugar in a bottle, and drain the dense solution into it through a filter, adding water slowly to the magma, until the solution of the iodides is displaced and the water measures twelve fluidounces. Lastly, agitate the bottle till the sugar is dissolved. Each fluidounce contains fifty grains of the iodides in the proportion of three parts of iodide of iron to one of iodide of manganium. The dose is the same as the preceding. Both syrups contain some potassium sulphate.

MANGANESII LACTAS.—Lactate of manganium is formed by adding manganous carbonate to hot lactic acid; on evaporating the filtrate, the salt is obtained in pale rose-red shining crystals, which contain 19 per cent. of water of crystallization, are soluble in 12 parts of cold water, and dissolve likewise in hot alcohol, crystallizing again on cooling.

MANGANESII PHOSPHAS.—Manganous phosphate is obtained by precipitating 10 parts of manganous sulphate with 11 parts or sufficient of phosphate of sodium, each separately dissolved in about 80 parts of water, washing the precipitate well to remove the sodium sulphate, and drying. It is a white crystalline powder, sometimes with a reddish tint, having the composition $Mn_32PO_4.4H_2O$, and dissolving readily in dilute acids. A syrup has been recommended by T. S. Wiegand (1854); the salt may be dissolved in dilute muriatic, or, better still, in phosphoric acid, and sufficient sugar dissolved in the cold solution.

MANGANESII TANNAS.—Tannate of manganium was recommended by Marletta (1865). It is obtained by adding recently precipitated manganous carbonate to a hot solution of tannic acid in distilled water, until it ceases to dissolve, filtering, and evaporating to dryness. The carbonate must be absolutely free from iron, and the solution must be protected from contact with iron, otherwise it will acquire an inky color. The salt is soluble in water, and when prescribed in solution, syrup or glycerin should be added for preservation.

MANGANESII TARTRAS, Tartrate of manganium.—On dissolving 10 parts of Rochelle salt and 8 parts of manganous sulphate each in its own weight of hot water, and mixing the solutions, small white or pale-reddish crystals of manganous tartrate are obtained on cooling, which must be washed with cold water, since hot water decomposes them into a soluble acid and an insoluble basic salt.

Physiological Action.—The sulphate of manganese is as energetic as the black oxide is inert. In experiments upon animals, when given internally in large doses it occasions vomiting and gastro-intestinal inflammation; injected into the veins it causes vomiting and purging, dyspnœa, rapid exhaustion, paralysis, and death, and, after this, traces of gastro-intestinal inflammation, and even ulceration, with congestion of the liver and spleen, while liquid or coagulated blood is found on both sides of the heart. In some experiments it is stated that a profuse secretion of bile was observed. It is generally affirmed that this salt possesses the qualities of caustic potassa or soda, dissolving the tissues, and in no wise the astringent action of iron salts.

More than half a century ago Gmelin performed the experiments with sulphate of manganese which are summarized in the preceding paragraph.

More recent experiments have shown that the salts formed by manganese with organic acids weaken the heart's action, prolong its diastole, diminish the arterial blood pressure, tend to paralyze the muscular system, and increase the excretion of nitrogenous compounds. Apparently ignorant of these experiments or of their bearing, a non-medical scientist on the one hand, and on the other a pharmacist and a surgeon, drew the conclusion that because manganese had been detected in the blood, and because in its chemical habitudes it closely resembles iron, therefore it must possess therapeutical virtues analogous to those of iron, and might be used at least to reinforce the latter metal. The folly of some of these theorists went even so far as to suggest the idea that, inasmuch as in nearly all martial preparations there is some manganese, they may possibly derive their virtues from it and not from the iron they contain. The above statement of the physiological action of manganese exhibits the absolute antagonism of its action to that of iron in every point.

Medical Uses.—Sulphate of manganese has been employed as a *cholagogue* purgative in jaundice and other affections associated with hepatic engorgement; but its irritating qualities render it an unsafe remedy. The *dose* of one or two drachms indicated for this purpose cannot be safely given. Its advantages as a substitute for iron are quite illusory. An ointment of this salt, which acts as an irritant upon the skin, has been applied by friction to *glandular indurations* and swellings of the *joints*. The chloride has occasionally been used to stimulate indolent *ulcers*, especially those of syphilitic origin; but it possesses no superiority over the usual topical applications made for this purpose.

MANNA, *U. S.*, *Br.*—MANNA.

Manne, Fr.; *Manna*, G.

The concrete saccharine exudation in flakes, of Fraxinus ornus, *Lin.* (s. Ornus europæa, *Pers.*). Steph. and Church, Med. Bot., plate 53; Bentley and Trimen, Med. Plants, 170.

Nat. Ord.—Oleaceæ.

Origin.—The manna ash, or flowering ash, is a slender tree about 12 to 20 feet high, with opposite pinnate leaves and small white diandrous flowers grouped together on a terminal, drooping, very elegant panicle. It is indigenous to the countries bordering the Mediterranean on the north, from Asia Minor west to Spain, and has been introduced into Central Europe and England as an ornamental tree. The foliage, even on the same tree, is frequently very variable, and *Fraxinus rotundifolia*, Lam., cannot be regarded as a distinct species, nor even as a well-marked variety.

Collection.—Manna is at present collected for commercial purposes solely in Sicily, as was ascertained by Hanbury, the plantations or *frassinetti* being chiefly on the northern shore of that island. When the tree is about eight years old, and its trunk at least 3 inches in diameter, it will yield manna and remain productive for ten or twelve years, when the stem is cut down and replaced by a shoot from the stump. The incisions are made in dry weather with a hooked knife, one each day, commencing near the root, and directly above each other; they are transverse, 2 inches or less in length, and penetrate through the bark to the wood. In the following year the same operation is repeated on the untouched side, and this is continued from year to year until the tree ceases to be productive. The juice flowing from the lower incisions is collected on tiles or in receptacles made from the stem of an opuntia; that from the upper incisions hardens on the stem, or, for producing a superior variety called *manna a cannolo*, which does not enter commerce, is allowed to harden on sticks or straws, inserted into the cuts. When sufficiently hard the large pieces are gathered, and completely dried before being packed, while the smaller ones are afterwards scraped from the stem and sold separately. The annual exportation averages about 3000 cwt.

Description.—The varieties of manna generally distinguished in our commerce are *large flake*, *small flake*, and *sorts*. Flake manna consists of three-edged pieces varying in length from $\frac{1}{2}$ inch to 6 or 8 inches, $\frac{1}{2}$ to 1 or 2 inches wide, and somewhat less in thickness; flat or curved on one side where it adhered to the tree, and uneven from roundish projections on the others, showing the marks of different layers. It is externally of a yellowish-white, in some places pale-brownish color, friable, internally porous, and the cavities filled with white glistening crystals of mannite. Its odor is saccharine, somewhat nauseous, and its taste sweet and honey-like, but combined with a very slight bitterness and acridity. Large and small flake manna differ only in size, the latter, however, being often of a darker shade. Manna in sorts consists of the scrapings, and is met with in fragments of the size of a pin's head to about $\frac{1}{2}$ inch in diameter, with a rather adhesive surface, and of a brownish color outside, but internally nearly white and crystalline; not unfrequently the fragments are united by a viscid brownish matter, which, without the flakes, constitutes *fat manna*, a variety rarely seen in this country. It flows from the incisions late in autumn, and is more particularly yielded by old trees; it is soft and glutinous, entirely devoid of crystals, and less agreeable in odor and taste than flake manna, from which it differs in containing much less mannite and more gum, sugar, and coloring matter.

Manna dissolves in about six parts of cold water, yielding a nearly clear solution, and is soluble in alcohol, leaving little residue.

Sophistication.—Manna has occasionally been sophisticated by mixtures made of bread-crumb, starch, glucose, etc., which are very readily discovered if practised with flake manna; starchy substances can also be readily detected in manna sorts by the iodine tests.

Constituents.—The best flake manna contains about 90 per cent. of *mannite*, the remainder being fermentable *sugar*, *resin*, and *mucilage*. Mannite, $C_6H_{14}O_6$, was discovered by Proust (1806), and may be obtained by treating manna with boiling alcohol, and recrystallizing several times from hot alcohol. Chas. T. Bonsall (1853) recommends the dissolving of manna in three times its weight of boiling water, precipitating gum and coloring matter by a little subacetate of lead, removing excess of lead by sulphuretted hydrogen or a little sulphuric acid, concentrating the filtrate and pouring the hot syrupy liquid into twice its bulk of cold alcohol; the mannite will crystallize on cooling. It crystallizes in colorless needles or glossy rhombic prisms, which fuse at 165° C. (329° F.), and boil near 200° C. (392° F.), when a portion sublimes unaltered, but most of it is converted into *mannitan*, $C_6H_{12}O_5$, a sweetish syrupy liquid. Mannite dissolves in about 6 parts of cold and in much less hot water, in 90 parts of cold 67 per cent. alcohol, and is insoluble in ether and nearly so in absolute alcohol. The solutions scarcely affect polarized light, are not altered by boiling with dilute acids, and do not reduce Fehling's solution. It unites with bases, forming compounds, which are insoluble in alcohol. Nitric acid converts it into racemic acid and sugar, and ultimately into saccharic and oxalic acids. Gorup-Besanez (1861) observed that moist platinum-black converts it into *mannitic acid*, $C_6H_{12}O_7$, and *mannitose*, $C_6H_{12}O_6$, which is fermentable, but optically inactive. Berthelot (1856) has shown that under certain circumstances mannite will undergo alcoholic fermentation. Mannite has been found in a large number of plants, is formed in small quantity during the alcoholic fermentation of sugar, and may be obtained artificially by acting upon glucose with sodium-amalgam.

The fermentable sugar present in manna reduces Fehling's solution very readily, and the mucilaginous matter is precipitated by acetate of lead. The resin is soluble in ether, and has a brown-red color and an acrid taste. The green color observed in some pieces of manna is due to *fraxin*, $C_{32}H_{36}O_{20}$, which was discovered by Salm-Horstmar (1857) in the bark of *Fraxinus excelsior*, the European ash (see pages 650 and 698), and splits with dilute acids into glucose and *fraxetin*, $C_{10}H_8O_5$.

Other Mannas.—The exudations of various trees have received the name of manna; that sometimes obtained in Southern Europe from incisions into the trunk of Fraxinus excelsior, *Lin.*, is identical with the foregoing. The leaves of the European larch, Pinus larix, *Lin.*, yield in the middle of summer a white exudation known as *Briançon manna*, and containing the sugar *melezitose*, $C_{12}H_{24}O_{12}$. The leaves of Eucalyptus viminalis, *Labil.*, of Australia, yield *Australian manna*, containing *melitose*, $C_{12}H_{28}O_{14}$. *Persian manna* comes from Alhagi camelorum, *Fisch.*, Leguminosæ, and contains spines and leaflets of the plant. *Tamarisk manna* exudes from Tamarix mannifera, *Ehrenb.*, in consequence of the puncture made by an insect, Coccus manniparus, *Ehrenb.*, and is collected near Mount Sinai, and sold by the monks of the convent St. Catharine; it contains cane-sugar, glucose, and dextrin. *Armenian* (*oak*) *manna* results from the puncture of a coccus upon the leaves of Quercus vallonea, *Kotschy*, and Q. persica, *Jaub. et Spach;* it is either dissolved from the leaves by water which is evaporated, or else scraped off, and then is mixed with numerous small fragments of the leaves; it consists chiefly of grape sugar. *Lebanon manna* is in small sweet grains obtained from Cedrus libanotica, *Link*. Saccharine exudations have been observed upon a number of other plants, and the saccharine products of some insects, like the *trehala* (*tigala*) of Syria, containing the peculiar sugar *trehalose*, and the *lerp* of Australia, have sometimes been classed with the mannas; they are not entirely soluble in water.

Medical Uses.—Manna has been much used as a *laxative* peculiarly adapted to children and pregnant women; it is also a gentle *cholagogue*, and at the same time a suitable *expectorant* in febrile affections of the lungs. Some writers have held it to be peculiarly fitted, owing to the mildness of its action, to be employed in cases of *genito-urinary irritation.* It is slow in its operation, and is not apt to leave the bowels confined, but it tends to occasion flatulence and colic. Formerly, as at the present day, it was often associated with rhubarb, tamarinds, or senna; and it forms one of the ingredients of *the black draught:*—℞. Sennæ, ℥ss; Magnesiæ sulph., Mannæ, āā ℥ss; Sem. fœniculi, ʒj; Aquæ bull., Oss.—M. Macerate in a covered vessel until the liquid cools. One-third of it may be given every four or five hours, until it operates. The same infusion may be made with cold water by percolation. It is less nauseous, and has a slighter tendency to gripe.

MARANTA, *U. S.*—ARROWROOT.

Amylum marantæ, P. G.—*Arrowroot*, Fr., G.; *Salep des Indes occidentales*, Fr.; *Marantastärke*, G.

The fecula of the rhizome of Maranta arundinacea, *Lin.* Bentley and Trimen, Med. Plants, 265.

Nat. Ord.—Cannaceæ.

Origin.—The maranta is a perennial herb with a branching, fleshy, cylindrical rhizome, either covered with whitish scales or annulate with their scars. The slender branching stem is 5 to 6 feet high, has thickened nodes, ovate lanceolate leaves with long sheaths, and small whitish flowers, usually in pairs at the ends of the branches. The plant is indigenous to the West India Islands and Central America, and is largely cultivated in the Bermudas, in Georgia, and in Brazil. *M. indica*, Tussac, is now regarded by botanists as being identical with the preceding; it is found in Bengal, Java, and the Philippines, and has been introduced into tropical America and Africa.

Fig. 104.

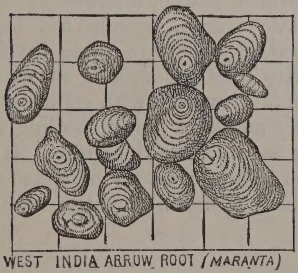


Fig. 105.

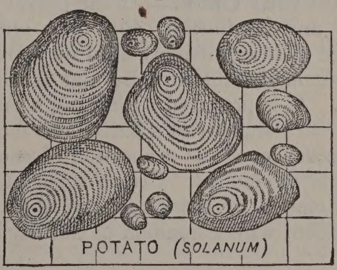


Preparation.—When about a year old the rhizomes are dug up, carefully cleaned from the scales, well mashed, and either ground in a mill or rasped until reduced to a pulp, which is suspended in water, the fibrous portion being either separated by hand or by sieves. The starch which settles from the water is repeatedly stirred with fresh portions of clean water, finally allowed to settle, and dried with a gentle heat. The rhizomes yield from 13 to 20 per cent. of fecula. (See papers by Robert Battey in *Proceedings of the Amer. Pharm. Assoc.*, 1858, p. 332, and by W. Eberhard in *Archiv d. Pharm.*, 1868, vol. 184, p. 257.)

Description.—Arrowroot is pulverulent or in small irregular lumps less than $\frac{1}{4}$ inch thick, white, opaque, tasteless and inodorous, and has the general properties of starch. Under the microscope it is seen to consist of ovate or somewhat oval granules, the layers of which are marked by fine but distinct lines, and have upon the broader end a small nucleus or a transverse fissure; the granules are nearly uniform in size.

Substitutions and Adulterations.—*East India arrowroot* is frequently maranta starch, but sometimes consists of the starch of *Curcuma leucorrhiza* and *angustifolia*, Roxb., which is in flattened elliptic or elongated ovate granules, marked with numerous fine lines and at the narrow end with a hilum. For an account of the canna and manihot starch, see the articles *Canna* (p. 334) and *Tapioca*. *Potato starch* is sometimes substituted for arrowroot or used for adulterating it; the granules are of two sizes, a portion being small and subspherical, another portion larger than maranta starch, of an ovate or irregular oval shape, marked with rather coarser lines, and with an inconspicuous hilum at the narrowed end. *Other starches* which may be used for adulteration are easily recognized by means of the microscope.

Tests.—According to the German Pharmacopœia, 1 part of arrowroot gives with 96 parts of boiling water a moderately thin pellucid mucilage; and when it is agitated for 10 minutes with a mixture of 2 parts of muriatic acid and 1 part of water, nearly the whole of the starch should separate unchanged and without the formation of a mucilage or the production of an herbaceous odor. Schaer (1875) has shown that some samples of maranta starch yield in a short time a turbid jelly which gradually becomes limpid, while in most cases it separates unchanged, but is partly dissolved within twenty-four hours. This difference is probably due to climatic influences. The starches of manihot and curcuma have a similar behavior; wheat starch yields no jelly, but, after several hours, a strongly opalescent solution. Potato starch, however, is very readily transformed into a thick, almost clear jelly, forming a complete solution in a few hours, and having a strong herbaceous or bean-like odor.

Preservation.—Arrowroot, like other starches, should be kept in a dry place. In the presence of moisture, and when kept in well-closed vessels, it acquires a musty odor, from which it may be freed by washing with much pure water, after which it should be rapidly dried.

Off. Prep.—Trochisci ipecacuanhæ.

Medical Uses.—As the purest natural form of starch, arrowroot is nutritious and demulcent, and does not, like potato starch, irritate the bowels. Hence it is extensively used in *febrile affections*, especially in those involving the stomach and bowels, and is also a favorite food for infants at weaning time. It is prepared by mixing a tablespoonful of arrowroot with sufficient cold water to reduce it to a paste, and then gradually adding a pint of boiling water (or milk), or a due proportion of each, stirring the mixture the while. It may then be sweetened. Cream is sometimes mixed with the watery mucilage when the stomach or bowels are irritable. In exhausting diseases a little wine may be added, with cinnamon or nutmeg.

MARMOR, *U. S.*—MARBLE.

Marmor album, Br.—*Marbre*, Fr.; *Marmor*, G.
Formula $CaCO_3$. Molecular weight 100.

Native white granular carbonate of calcium.

Properties.—Marble is found in various parts of the globe, the white kind being nearly pure carbonate of calcium, while the colored varieties are more or less tinged or variegated by the presence of oxides of iron and manganium or by bituminous matter. It is met with in masses, which are an aggregation of minute crystals, imparting a granular and glistening appearance. It has the specific gravity 2.7, is brittle, hard, insoluble in the ordinary solvents, but entirely soluble in dilute muriatic acid, carbonic acid gas being given off. It is used in pharmacy for generating the gas mentioned, for which purpose black marble containing bituminous compounds is inadmissible, but other varieties may be used. In case the solution in hydrochloric acid is to be used for the preparation of other calcium compounds, it must be completely freed from iron by digesting it with milk of lime, and, after filtration, should not be precipitated by a solution of sulphate of calcium (absence of barium and strontium), nor by ammonium phosphate, after the previous addition of excess of ammonium chloride and ammonium carbonate and filtration (absence of magnesium).

Marble has the same composition as chalk, and when heated to redness parts with carbonic acid gas, leaving lime or oxide of calcium, CaO.

Pharmaceutical Uses.—In producing carbonic acid gas and for preparing Liquor calcii chloridi.

MARRUBIUM, *U. S.*—HOREHOUND.

Herba marrubii.—Hoarhound, E.; *Herbe de marrube blanc*, Fr.; *Andornkraut*, *Weisser Andorn*, G.

The leaves and tops of Marrubium vulgare, *Lin.* Bentley and Trimen, Med. Plants, 210.

Nat. Ord.—Labiatæ, Stachydeæ.

Origin.—Horehound is a perennial herb, and is found in waste places in Asia, from Northern India westward to the Mediterranean, and throughout Europe except the extreme north; it has been naturalized in Canada and in many parts of the United States westward to California, also in some parts of South America. It is not unfrequently met with in gardens, and it flowers from June to September.

Description.—The branching stem is about a foot high, quadrangular, covered with a white felt. The leaves are opposite, petiolate, about an inch long, roundish-ovate, somewhat heartshaped or rounded at the base, obtuse, serrate or coarsely crenate, wrinkled by the prominent veins below, pale green and downy above, and white hairy beneath. The flowers are in dense axillary whorls, with woolly, linear, and hooked bracts, a tubular ten-ribbed calyx divided into 10 short, spreading, stiff, and hooked teeth, and a white bilabiate corolla inclosing four stamens. The four akenes are dark brown.

Horehound has a strong, peculiar, and aromatic odor, and an aromatic and persistent bitter taste.

Constituents.—Horehound contains, besides some resin, tannin, and other common principles, a small quantity of volatile oil, and *marrubiin*, a bitter principle discovered by Mein (1855). Harms obtained 30 grains from 25 pounds of the dry herb by treating the aqueous extract with alcohol, distilling the latter, and agitating the residue with ether, which dissolves the marrubiin. Kromayer (1861) agitates the infusion with charcoal, and exhausts the latter with hot alcohol, which dissolves the bitter principle and tannin; the latter is removed by oxide of lead. Marrubiin is slightly soluble in cold water, crystallizes from alcohol in prismatic and from ether in tabular crystals, is not precipitated by tannin, and has a very bitter and somewhat acrid taste.

Medical Uses.—Anciently regarded as a general stimulant, expectorant, deobstruent, carminative, and local anodyne, horehound continues to be employed as a stomachic tonic in *dyspepsia*, and in *chronic bronchitis* to restrain secretion. It has also been used in chronic rheumatism, hepatic and uterine disorders, and, like other bitter herbs, in intermittent fever. It has some reputation as an *anthelmintic*, and is said to diminish salivation. The *dose* of the powder is stated to be from thirty to sixty grains. An infusion made with an ounce of horehound in a pint of hot water may be given in doses of a wineglassful. The expressed juice should be administered with honey or milk, in the dose of a teaspoonful or two several times a day. An extract is prepared in Europe.

MASTICHE, *U. S.*, *Br.*—MASTIC.

Mastix, P. G.; *Resina mastiche.*—*Mastich*, E.; *Mastic*, Fr.; *Mastix*, G.

The concrete resinous exudation from Pistacia lentiscus, *Lin.* Woodville, Med. Bot., t. 11; Bentley and Trimen, Med. Plants, 68.

Nat. Ord.—Anacardiaceæ.

Origin.—A small tree or shrub, which is indigenous to the basin of the Mediterranean, has pinnate leaves with leathery sessile leaflets, varying in form between linear and ovate, short-stalked reddish-yellow pistillate, and larger greenish staminate flowers, and small blackish drupes. Mastich is obtained in a few islands of the Grecian Archipelago, principally in Scio, from the var. γ *Chia*, which is tree-like and has broad leaves.

Collection.—The resin being secreted in the bark, vertical incisions are made in June and July in the bark of the trunk and larger branches; and in July and August, after the exuding resin has hardened, it is carefully removed from the tree and collected in baskets; this is the finest quality. An inferior quality consists of the tears which have dropped from the incisions upon tiles or flat stones kept under the tree. A vigorous tree may yield 10 lbs. of mastich; the total harvest is very variable, and occasionally reaches 50,000 cwt., but is generally considerably less.

Description.—The best quality of mastich is in globular or more or less elongated tears of the size of a pea, which are externally covered with a whitish dust, or have been freed from it by washing, and are then of a pale-yellow color, perfectly transparent, of a glass-like lustre, and break readily with a conchoidal fracture. Placed between the teeth, it is easily crushed and then softens into a plastic mass. Its specific gravity is about 1.07; it becomes soft below the boiling point of water, but fuses at some degrees above it. It has a balsamic odor, more apparent on being heated, and a slight terebinthinous taste. It dissolves partly in alcohol, and is also soluble in benzol, acetone, volatile oils, cold creasote, and warm petroleum, leaving a whitish residue. The alcoholic solution reddens litmus.

The inferior kinds of mastich consist of similar tears, to which sand and fragments of bark adhere, mixed with gray- or brown-colored pieces.

Constituents.—Mastich contains a minute quantity of *volatile oil*, and about 90 per cent. of *alpha-resin* or *mastichic acid*, which is soluble in cold alcohol, combines with bases, and, according to Johnston, has the composition $C_{20}H_{32}O_2$. The portion insoluble in alcohol is white, tenacious, soluble in ether and oil of turpentine, and has been named *beta-resin* or *masticin;* its composition is $C_{20}H_{31}O_2$.

Varieties and Adulterations. *Bombay mastich.*—Under this name a drug has appeared in the market, which, when well selected and clean, closely resembles the Scio mastich, but is usually in less clean and more opaque tears. It is obtained from *Pistacia cabulica* and *khinjuk*, Stocks, which are indigenous to Northwestern India and Beloochistan.

Substitutions and admixtures are of comparatively rare occurrence. *Sandarac* is readily distinguished by the tears being more elongated, less perfectly transparent, almost wholly soluble in alcohol, and becoming pulverulent when masticated; it is obtained in Northwestern Africa, from Callitris quadrivalvis, *Ventenat; Nat. Ord.* Coniferæ, Cupressineæ. The tears of *olibanum* are generally larger, translucent, and destitute of glassy lustre. The exudation of Atractylis gummifera is sold in Greece as *pseudo-mastich* or *acantho-mastich*, and consists of agglutinated tears which are oblong in shape and about 2 inches long by one inch in thickness.

Off. Prep.—Pilulæ aloes et mastiches, *U. S.*

Medical Uses.—Formerly employed internally for purposes similar to those for which other terebinthinates are prescribed, its medicinal use is now almost entirely restricted to forming a solution in ether with which cotton may be saturated for the purpose of filling *carious teeth*, and protecting their tender surface from the influence of cold and the contact of food during mastication. A solution of it in alcohol may be applied to arrest bleeding from leech-bites and other slight wounds. Mastich is an ingredient of the "dinner pill" (Pil. aloes et mastiches).

MATICO, *U. S.*—MATICO.

Maticæ folia, Br.—*Feuilles de matico*, Fr.; *Maticoblätter*, G.

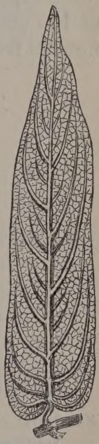
The leaves of Artanthe elongata, *Miquel*, s. Piper angustifolium, *Ruiz et Pavon*, s. Steffensia elongata, *Kunth*. Bentley and Trimen, Med. Plants, 242.

Nat. Ord.—Piperaceæ.

Origin.—A shrubby plant, about 8 feet high, sometimes cultivated, and found in moist woods of tropical America, from Mexico southward to Venezuela, Brazil, and Peru. The minute yellowish flowers are very numerous, aggregated into a solid, cylindrical, slender spike, about 6 inches long, and produce blackish fruits of the size of a poppy seed.

Description.—The leaves, which are very frequently mixed with branches and spikes of flowers or fruits, are rather thick, about 6 inches long, oblong-lanceolate, entire, narrowed at the apex to a blunt point, heart-shaped, and somewhat unequal at the base, and have a very short petiole. The upper surface is nearly smooth, of a green color, and very uneven or tessellated in appearance from the depressed veins, which are prominent beneath, making the downy lower surface reticulate, the meshes being small, and the veins densely covered with brownish hairs. The leaves, particularly when rubbed between the fingers, have an aromatic odor, and a warm, aromatic, bitterish taste.

Fig. 106.



Matico Leaf.

Constituents.—Matico contains about 1½ per cent. of a thickish, pale yellow, volatile oil, consisting of two oils, one of which is sometimes heavier than water. Wiegand (1846) proved the non-existence of Hodges' maticin. Stell (1858) showed the absence of piperina and cubebin, and obtained a ruby-colored resin of a very acrid and pungent taste. Subsequently Marcotte isolated a crystallizable acid, named *artanthic acid*. Matico contains also some tannin, and other principles common to vegetables.

Substitutions.—In different parts of South and Central America, the Spanish names *matico*, and *yerba* or *palo del saldado* (soldier's herb or tree) are given to other plants besides the one described above, namely, to Eupatorium glutinosum, *Kunth* (Compositæ), and Waltheria glomerata, *Presl.* (Sterculiaceæ), the leaves of which are likewise used for arresting hemorrhage. Artanthe (s. Piper) lanceæfolia, *Miquel*, is similarly used in New Granada. Bentley (1864) met with the leaves of Artanthe adunca, *Miq.* (Piper aduncum, *Lin.*), which were offered as matico. They are similar in shape, and the upper surface is marked by some sunken, ascending, and parallel nerves, and the lower surface by corresponding reticulations, but they have not the tessellated appearance nor the roughness and hairiness on the lower surface observed on the officinal matico leaves; their properties appear to be the same.

Off. Prep.—Infusum maticæ, *Br.;* Extract. matico fluid., *U. S.*

Medical Action and Uses.—In its nature and operation matico closely resembles the terebinthinate medicines, while its odorous and special stimulant qualities rank it with cubeb and copaiba. Like these substances, it is absorbed into the blood, and appears to produce a constriction of the capillary vessels, whereby it controls mucous fluxes and hemorrhages, while it occasions more or less diuresis. It has been employed, like copaiba, in the treatment of *bronchitis*, *gonorrhœa*, *leucorrhœa*, *vesical catarrh*, and *chronic diarrhœa* and *dysentery*, and in *hemorrhage* from the *lungs*, *stomach*, *bowels*, *rectum*, and *kidneys*. Like oil of turpentine, it has been used as a topical hæmostatic. The *dose* of the powder is from half a drachm to two or three drachms several times a day. An extract has been made, of which the dose is from sixty to seventy-five grains. The infusion and tincture are officinal.

MATRICARIA, *U. S.*—GERMAN CHAMOMILE.

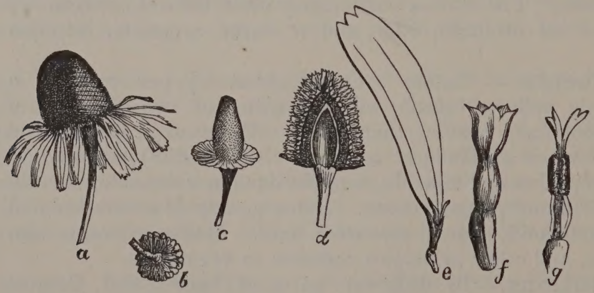
Flores chamomillæ vulgaris, P. G.—*Fleurs de camomille commune (d'Allemagne)*, Fr.; *Kamille*, *Kamillenblumen*, G.

The flowers of Matricaria chamomilla, *Lin.*, s. Chamomilla officinalis, *Koch.* Bentley and Trimen, Med. Plants, 155.

Nat. Ord.—Compositæ, Senecionideæ.

Origin.—An annual herb, with a branching stem about a foot high, smooth, twice or thrice pinnatifid leaves, with spreading setaceous segments and numerous flower-heads terminating the slender branches. The plant is common in fields and waste places throughout Europe as far north as Finland, and in the temperate parts of Asia; it has been completely naturalized in Australia, and is occasionally cultivated in German settlements in the United States. It flowers from May till August.

Fig. 107.



Matricaria.—*a.* Flower-head; *b.* Involucre; *c.* Receptacle and involucre; *d.* Longitudinal section of receptacle, with disk florets; *e.* Ray floret; *f.* Disk floret; *g.* Stamens and style of disk floret.

Description.—The flower-heads are $\frac{1}{2}$ to $\frac{3}{4}$ inches broad, and have a flattish involucre, with two or three rows of small, oblong-linear, obtuse scales, having the margin membranous. The receptacle is at first convex, but becomes strongly conical and hollow, and is free from chaff. The ray-florets are about fifteen in number, soon reflexed, white, ligulate, oblong, with two notches at the apex, and inclosing the bifid style, but no stamens. The numerous yellow disk-florets are tubular, 5-toothed, somewhat glandular, hermaphrodite, and have the anthers united into a tube through which the bifid style projects. The akenes are small, curved, 5-ribbed, brownish, without pappus, but with a slightly elevated margin at the apex. German chamomile flowers have a peculiar aromatic odor, and a bitterish, aromatic taste. They are easily distinguished from allied composite plants by their smooth, conical, and hollow disks, which shrink very considerably on drying.

Constituents.—German chamomile flowers contain about $\frac{1}{4}$ per cent. of volatile oil, some bitter extractive, malates, tannates, and a little tannin, besides the principles common to vegetables.

The volatile oil, *oleum chamomillæ æthereum*, P. G., is a dark blue, in thin layers, transparent, thickish liquid, which gradually turns green and brown when exposed to light and air, and more rapidly if obtained from dried flowers; it has a strong odor of the flowers, and a warm, aromatic taste; dissolves in about 8 parts of 80 per cent. alcohol, has the specific gravity 0.93, and seems to consist of a terpene $C_{10}H_{16}$, associated with $C_{10}H_{18}O$. The blue color is due to the presence of a volatile principle, which was named *azulene* by Piesse, and *cœrulein* by Gladstone (1863), and which, according to both investigators, is present in all other volatile oils having a blue or green color; in the latter associated with a yellow principle.

An oil of German chamomile, containing oil of lemon, is still sometimes met with in our market; it was formerly officinal in Europe as *Oleum chamomillæ citratum*, and, according to the late Prussian Pharmacopœia, prepared by adding to 480 parts of recently collected flowers, one part of oil of lemon, and then distilling with water; it has a deep blue color, but is more limpid than the pure oil, and more prone to change in color.

OLEUM CHAMOMILLÆ INFUSUM, P. G., is employed externally, and made by macerating 2 parts of the flowers with 1 part of alcohol for several hours, and then digesting with 20 parts of olive oil until the alcohol has been expelled, expressing and filtering; it has a yellowish-green color.

Medical Uses.—German chamomile has less agreeable qualities than English chamomile (*anthemis*), but medicinally may be substituted for it.

MEDEOLA.—MEDEOLA.

The rhizome of Medeola (Gyromia, *Nutt.*) virginica, *Lin.*

Nat. Ord.—Liliaceæ.

Origin.—The medeola or *Indian cucumber* grows in damp soil in woods and shady places of the United States, and flowers in June. It has a slender stem, about 18 inches high, beset with a deciduous fine wool, and bearing above its middle a whorl of 6 or 8 spreading oblong-lanceolate leaves, which are about 3 inches long, and acute at both ends. Near the top is a whorl of 3 or 4 smaller ovate pointed leaves, and above them 3 or 4 greenish-yellow recurved flowers, having 6 sepals and stamens, and producing a purplish-blue three-celled berry, each cell containing about 5 triangular seeds.

Description.—The rhizome is horizontal, 1 or $1\frac{1}{2}$ inches long, about $\frac{1}{4}$ inch thick, pointed at the lower end, beset with hair-like simple rootlets, pale brown-yellowish externally, white internally, and with few small wood-bundles. It is without odor, and has a sweetish, in the fresh state somewhat cucumber-like, taste. Its constituents, among which is starch, have not been investigated.

Medical Action and Uses.—There appears to have been nothing added for many years to the scanty knowledge originally possessed of this root, viz.: that it was reputed to be hydragogue and diuretic, and therefore useful in dropsies.

MEL, *U. S.*, *Br.*—HONEY.

Miel, Fr.; *Honig*, G.

A saccharine secretion deposited in the honey-comb by Apis mellifica, *Lin.*, the hive bee.

MEL DESPUMATUM, *U. S.*—CLARIFIED HONEY.

Mel depuratum, Br., P. G.—*Miel despumé*, *Mellite simple*, Fr.; *Gereinigter Honig*, G.

Origin.—A saccharine liquid is secreted by the nectaries of flowers and collected by the working bees in their so-called honey-bags, where it probably undergoes some changes before it is disgorged again in the hive. Evidently the source from which it has been collected by the bees must exert considerable influence on its flavor, and it may even contain injurious principles when the flowers of poisonous plants have been frequented by the bees; to this cause at least have been referred cases of poisoning which occurred after partaking of honey. It has been stated that honey bees introduced into Australia ceased to produce honey after the first year, probably because in that climate they could collect the necessary food during the entire year. Honey is largely produced in Europe and North America; much that is used in the United States is imported from the West Indian Islands, and recently a well-flavored honey from California has been introduced in the Atlantic States.

Preparation.—The finest honey, called virgin honey, is obtained simply by draining the comb; when pressure or heat is used a darker colored product is obtained. The yield of a hive is about 15 to 20 pounds (see paper by B. F. Creighton, in *Amer. Journ. Phar.*, 1875, p. 487).

Clarification.—Take of Honey a convenient quantity. Melt it by means of a water-bath, and then remove the scum. *U. S.*

The object of clarification is to remove the wax and other impurities of honey, which rise to the surface when the honey is kept for awhile in the condition of a thin fluid by exposing it to the heat of a water-bath. The British Pharmacopœia directs it then to be strained through flannel previously moistened with water. The French Codex dissolves four parts of honey in one part of water, heats the mixture, removes the scum, clarifies with paper pulp, strains, and evaporates to the proper density. The German Pharmacopœia orders honey to be diluted with twice its weight of water, heated to 100° C. (212° F.) for one hour, filtered and evaporated. Various other methods have been suggested, among which may be mentioned the following: To dilute the honey with some water, add white of egg, heat gradually up to near boiling, strain and concentrate; or to add to 28 pounds of honey, diluted with water, a little (3 drachms) gelatin, heat and exactly precipitate the gelatin by (1 drachm) tannin; or to treat the diluted honey with prepared chalk, or with animal charcoal, or with both, or to interrupt the boiling repeatedly for about a minute by the addition of sufficient cold water, and after filtration to concentrate to the proper consistence. The long-continued heat necessary for concentrating diluted honey, impairs its aroma, and imparts to it a darker color. In our experience the first two processes give quite satisfactory results, though the product is never absolutely transparent, a result aimed at by the other processes.

Properties.—When recently prepared, honey is a nearly transparent, pale yellowish, or brownish syrupy liquid, which, on keeping, separates a granular deposit, and is ultimately changed into a crystalline mass intermixed with some liquid. It has an agreeable odor, differing more or less from causes mentioned above, and a sweet taste, followed by a slight acridity. In some parts of Africa a brown and even greenish honey has been observed, which may be produced by different species of *Apis*. Clarified honey has the same properties, except that it is more transparent.

Honey dissolves readily in water, also in diluted alcohol, yielding in both cases slightly turbid solutions which have a faint acid reaction.

Constituents.—The odor of honey is doubtless due to a minute quantity of volatile oil, which, according to Calloud, is intimately associated with a yellow coloring matter, *melichroin*, separated by the nectaries, and which is bleached on exposure to sunlight. A little wax and gummy matter are usually present; but the main constituents are *grape-sugar* or *dextrose* and *fruit-sugar* or *levulose*. The honey of an American wasp, *Polybia apicipennis*, according to Karsten, contains cane-sugar, and the same may be the case with honey from other sources; this constituent, however, is gradually changed to *invert sugar*, which is a mixture of grape- and fruit-sugars. It is the grape-sugar which renders honey granular, while the fruit-sugar remains liquid; the former turns polarized light to the right, the latter to the left. Honey has a specific gravity of 1.35 to 1.42.

Adulterations.—The coarse adulteration with starchy substances is easily recognized in the insoluble matter left on treating with dilute alcohol, and by the blue color produced on the addition of solution of iodine. Adulterations with artificial grape-sugar, prepared from starch by boiling with sulphuric acid, are difficult to establish. Aside from the physical properties, the presence of soluble sulphate (of calcium) affords the best criterion. E. Dietrich (1877) observed that, by dialyzing honey into water, the dialyzed portion, on concentration, had a golden-yellow color and a remarkably fine floral odor, while the residue upon the dialyzer was destitute of honey odor, and had a sweet but insipid taste.

Pharmaceutical Uses.—Clarified honey is used as an excipient for some *pill masses* and *confections*, as the basis of *mellita* and *oxymellita*, and is an ingredient in Pilula ferri carbon., Tinct. cardamomi comp., and Tinct. opii comp., *U. S.*

MELLITA. Medicated honeys, *E.*; Mellites, *Fr.*; Honige, *G.*—These are simply mixtures of honey with certain medicinal substances. Owing to their proneness to change, the number of these officinal mixtures has been considerably diminished, and, with but few exceptions, none are kept on hand, but are prepared extemporaneously when required by the physician.

OXYMELLITA, Oxymels, *E.*, *Fr.*, Sauerhonige, *G.*, are medicated honeys containing acetic acid (see Oxymel).

Medical Action and Uses.—Honey is one of the most ancient of medicines, and its nutritious qualities were always well known. Medical history shows that the Greeks and Arabians were well acquainted with its uses and the noxious qualities of certain kinds of it. Honey may be used with other food without any unpleasant effects in most instances; but there are persons who cannot take even a small quantity of it without feeling the head heavy or confused, while in others it causes flatulence or diarrhœa. Among the plants which bees producing poisonous honey frequent are *Nerium oleander*, *Azalea pontica*, *Daphne mezereum*, *Aconitum*, and *Kalmia latifolia*. The last, or mountain laurel, is the chief source of poisonous honey in this country. The symptoms it produces are dimness of sight, vertigo, a mild or furious delirium, abdominal pain, vomiting and purging, perspiration, convulsions, foaming at the mouth, and, in a few instances, death. In some cases an eruption also appears upon the skin, and there is soreness of the throat with hoarseness of the voice.

Anciently honey was employed for most of the medicinal purposes for which sugar is now used, and especially with barley water for bronchial affections and sore throats. Its use is almost exclusively local, and for the same purposes as of old, particularly to stimulate mucous surfaces, and even cutaneous sores, when their condition denotes impaired vitality. It is habitually employed to cure *aphthæ*, *thrush*, and *pseudo-membranous deposits*, but its efficacy is increased by the addition of muriatic acid, borate of sodium, chlorate of potassium, etc. Hence the officinal preparations *Mel rosæ*, *Mel sodii boratis*, etc. It is sometimes useful as an ingredient of poultices for *boils* and *carbuncles*, as an application to *fissures of the nipple*, etc., and is applied in plasters to the mamma for *drying up the milk.*

In this connection it may be mentioned that *propolis*, a resinous exudation with which bees cover the bottom of their hives, is reported to be beneficial in the treatment of acute and chronic *diarrhœa.*

MEL ROSÆ, *U. S.*—HONEY OF ROSE.

Mel rosatum, P. G.; *Mellitum rosatum.*—*Mellite de roses rouges*, *Miel rosat*, Fr.; *Rosenhonig*, G.

Preparation.—Take of Red Rose in moderately fine powder two troyounces; Clarified Honey twenty-five troyounces; Diluted Alcohol a sufficient quantity. Moisten the powder with half a fluidounce of diluted alcohol, pack it firmly in a conical glass percolator, and gradually pour diluted alcohol upon it until six fluidrachms of filtered liquid have passed. Reserve this portion, and continue the percolation until half a pint more of liquid is obtained. Evaporate this by means of a water-bath to ten fluidrachms, add the reserved liquid, and mix the whole with the clarified honey. *U. S.*

This process is essentially the one recommended by I. J. Grahame (1859), and aims to preserve in the reserved portion the main quantity of the little volatile oil present in the rose petals. The French and German Pharmacopœias direct the rose to be infused in six times its quantity of water, the infusion to be strained, and mixed with the honey, and concentration by evaporation by means of a water-bath.

Medical Uses.—Its agreeable flavor and slight astringent and stimulant virtues render it a very pleasant and useful addition to water as a mouth-wash and gargle; or it may be applied undiluted to the affected part. It is a convenient vehicle for the administration of aromatic sulphuric acid, and other acids.

MEL SODII BORATIS, *U. S.*—HONEY OF BORATE OF SODIUM.

Mel boracis, Br.—*Borax honey*, E.; *Miel boraté*, *Mellite de borax*, Fr.; *Boraxhonig*, G.

Preparation.—Take of Borate of Sodium in fine powder sixty grains; Clarified Honey a troyounce. Mix them. *U. S.*

Take of Borax in fine powder sixty-four grains; Clarified Honey one ounce. Mix. *Br.*

It is made extemporaneously.

Medical Uses.—This mixture, which should have been left to extemporaneous preparation, is a very useful application for *aphthous* and other *ulcers* of the mouth and fauces. It is equally curative in similar affections of the female *genital organs.*

MELILOTUS.—MELILOT.

Herba (*Summitates*) *meliloti.—Sweet clover*, E.; *Mélilot*, Fr.; *Steinklee*, *Melilotenklee*, G.

Melilotus officinalis, *Willd.*, and Mel. alba, *Lam.*

Nat. Ord.—Leguminosæ, Papilionaceæ.

Description.—Both plants are frequent in Europe, along roadsides and in cultivated ground, and have been, to some extent, naturalized in North America. They are about three feet high, smooth, and have entire awl-shaped stipules and trifoliate leaves, the former species with oval or obovate-oblong leaflets; the latter with the lower leaflets truncate and the upper ones lanceolate. The flowers are in erect racemes, and of a yellow (Mel. officinalis) or white color (Mel. alba). The German Pharmacopœia recognizes only the yellow melilot. Both species have an agreeable odor.

Constituents.—The odorous principle was observed by Vogel (1820), and supposed to be benzoic acid. Guillemette (1835) proved it to be identical with Guibourt's *coumarin*, obtained from tonka beans. It may be prepared by exhausting the herb with strong alcohol, distilling off most of the solvent, separating the fat, crystallizing, and purifying by recrystallization from alcohol. Coumarin, $C_9H_6O_2$, which has since been isolated from many odorous plants (see p. 657 and 806), crystallizes in colorless shining prisms, which fuse at 67° C. (152.6° F.), and are readily soluble in fixed and volatile oils, alcohol, and hot water.

When treated with sodium amalgam, it is converted into *melilotic* and *coumaric acids*, which are also present in the herb, sometimes in combination with coumarin. Both acids are crystallizable, and have a bitter taste. Melilotic acid, $C_9H_{10}O_3$, fuses at 82° C. (179.6° F.), and its salts, when strongly heated, yield phenol. Coumaric acid, $C_9H_8O_3$, is also obtained from coumarin by boiling it with concentrated potassa solution; it fuses at 195° C. (383° F.), and the solutions of its salts are fluorescent.

TONKA BEANS, *E.*, Fève tonka, *Fr.*, Tonkabohnen, *G.*, are the seeds of a papilionaceous tree of Guiana, Dipteryx (Coumarouna, *Aubl.*) odorata, *Willd.* They are nearly two inches long, somewhat two-edged, deeply wrinkled, blackish-brown, of a fatty lustre, and usually covered with a crystalline efflorescence of coumarin. The so-called English tonka beans, from Dip. oppositifolia, *Willd.*, are smaller, about an inch long, smoother, and contain less coumarin.

Medical Action and Uses.—The peculiar odor of melilot, which is closely analogous to that of tonka bean, of vanilla grass, etc., as well as its active properties, are attributed to a proximate principle, coumarin. Given to dogs in the dose of from seven to ten grains, this substance produced great and even fatal depression; and in man in the dose of from thirty to sixty grains it occasioned nausea, giddiness, depression, vomiting, and drowsiness. In Europe melilot is sometimes mingled with hay to stimulate the appetite of cattle; it is strewn among clothing and furs to protect them from moths; and is mixed with snuff to scent it. Formerly it was used in a variety of disorders, including colic, diarrhœa, dysury, dysmenorrhœa, and rheumatism, but at present it is only applied externally, in decoction or infusion, to allay *local pains*, especially in the abdomen and joints. These preparations are made with from half an ounce to an ounce of the flowering tops in a pint of water.

MELISSA, *U. S.*—BALM.

Folia melissæ, P. G.; *Herba melissæ.—Lemon balm*, E.; *Mélisse, Céline, Herbe au citron*, Fr.; *Melissenblätter, Citronenkraut*, G.

The leaves and tops of Melissa officinalis, *Lin.*

Nat. Ord.—Labiatæ, Satureieæ.

Origin.—Balm is a perennial herb, from the woody root-stock of which a number of branching, pubescent stems, two to three feet high, are produced. The plant is indigenous to Western Asia and Southern Europe, has become naturalized to some extent in the United States, and is not unfrequently cultivated. The variety α *citrata*, Bischoff, or lemon balm, is generally preferred, and is alone recognized by some of the European Pharmacopœias.

Description.—The leaves are about two inches long, petiolate, ovate, with a rounded or somewhat heart-shaped base, coarsely crenate-serrate at the margin, obtusely pointed at the apex, the upper surface with scattered hairs, the lower surface glandular in the axils of the nerves. The upper leaves are smaller, often softly pubescent on both sides, and at the base rather wedge-shaped. The axillary cymules are about four-flowered; the calyx is hairy, tubular, bell-shaped, with the upper lip three-toothed, and the lower two cleft. The milk-white or pale-purplish corolla has the tube curved upwards; the stamens are four in number, the lower pair longer, all converging towards the upper lip. The dried herb has a mild agreeable odor, in the variety mentioned above, somewhat like that of lemon; the taste is slightly bitter.

Melissa cordifolia, *Pers.*, is indigenous to Southern Europe, where it is sometimes medicinally employed; the leaves are larger and more woolly, and have a rather disagreeable odor; the plant is now regarded as a mere variety of M. officinalis.

Adulterations are not likely to be met with. The leaves of *Nepeta cataria*, Lin., var. β *citriodora*, have an odor resembling that of lemon balm; but they are cordate-ovate, of a gray-green color, soft, downy above and tomentose beneath, and by these characters are easily distinguished from melissa.

Constituents.—The leaves contain, besides the common constituents of plants, about $\frac{1}{8}$ to $\frac{1}{4}$ per cent. of volatile oil, which is colorless or yellowish, has a spec. grav. of about 0.89, dissolves in about five parts of alcohol spec. grav. 0.85, and contains a stearopten.

Medical Uses.—Balm tea is a popular and refreshing drink, when made with the fresh plant, and taken cold. The hot infusion of the dried plant is one of the mildest that can be used to favor the operation of diaphoretic medicines. It is officinal.

MENISPERMUM CANADENSE.—YELLOW PARILLA.

The rhizome of Menispermum canadense, *Lin.* *Nat. Ord.*—Menispermaceæ.

Origin.—The yellow parilla, or *Canadian moonseed*, is a North American climber, with peltate, roundish-cordate, and angular leaves, small clusters of greenish-yellow flowers, and black glaucous roundish, kidney-shaped drupes. The rhizome was formerly brought into commerce as *Texas sarsaparilla*, and its botanical source was established by R. P. Thomas (1855).

Description.—The rhizome is several feet long, about a quarter of an inch thick, cylindrical, when dry, with numerous fine longitudinal wrinkles, of a yellowish-brown color, and beset with thin branching rootlets. Internally it is yellowish, breaks with a tough fibrous fracture, and exhibits on transverse section a bark of about one-eighth the diameter of the rhizome, and composed of two distinct layers; a woody zone of the same thickness, consisting of short, nearly square porous wood wedges, separated by broad medullary rays, and a large central pith. The rhizome has a slight odor and a bitter taste.

Constituents.—We found (1863) the rhizome to contain a small quantity of berberina and a larger proportion of a white alkaloid, which is soluble in ether, alcohol, and much water, neutralizes acids completely, and yields precipitates with the group reagents for alkaloids. It also contains starch. The other constituents have not been investigated.

Medical Action and Uses.—It has been reputed for many years that moonseed is tonic, alterative, and diuretic, and that its medical qualities resemble those of sarsaparilla. It much more probably resembles colombo, not so much because, like that medicine, it yields berberina, as because it is bitter. We read that it is used in *scrofulous* affections as a substitute for sarsaparilla, but without the assurance that the latter medicine is itself of demonstrable utility in their treatment. Whatever virtues it may possess await the discovery of intelligent investigation.

MENTHA PIPERITA, *U. S.*—PEPPERMINT.

Folia (*Herba*) *menthæ piperitæ*, P. G.; *Menthe poivrée*, Fr.; *Pfefferminze*, G.

The leaves and tops of Mentha piperita, *Lin.* Bentley and Trimen, Med. Plants, 203.

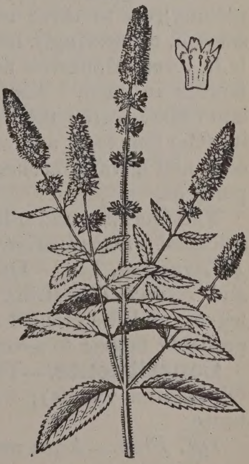
Nat. Ord.—Labiatæ, Satureieæ.

Origin.—Peppermint is a perennial plant, readily multiplying by runners, and with a square frequently purplish stem, about three feet high. Its native country is unknown; it is regarded as a mere variety of *M. hirsuta*, Lin., with which it is connected by many intermediate forms, and from which it was probably produced by cultivation. It is now found wild in wet places in England, in other countries of Europe, and in North America; it is largely cultivated. It flowers in August and September.

Description.—The leaves are 2 to 3 inches long, and all petiolate, the petioles being about half an inch long; they vary in shape between lanceolate and ovate-lanceolate, have a rounded base, an acute apex, and a sharply serrate margin; the upper surface is dark green, and smooth, the lower surface paler, with numerous glands, and upon the nerves sparingly pubescent. The inflorescence is terminal, consists of 12 to 16 whorls, the lowest of which are somewhat distant; it is conical in shape, rounded or acute above, and about 2 inches long; the cymules of each whorl contain about 20 or 30 flowers. The calyx is often purplish, tubular, 5-toothed, 10-ribbed, glabrous, but dotted with yellowish glands. The corolla is pale purplish-red, and smooth, with the tube about as long as the calyx, and the limb nearly equally four lobed. The four short stamens are equal in length, and included in the calyx tube. The fruit consists of four brownish smooth or rugose akenes.

Several varieties are known, differing in the width of the leaves, the amount of pubescence, and the compactness of the flowering spikes.

Fig. 108.



Mentha piperita. *Lin.*

Constituents.—The most important constituent is the volatile oil, of which the dried herb yields in the neighborhood of 1 per cent. (see Ol. menthæ piperitæ). A little tannin and the other constituents are of no medicinal importance.

Off. Prep.—Aqua menthæ piperitæ, Spiritus menthæ piperitæ, *U. S.*

Medical Action and Uses.—The name peppermint denotes the sharp, biting taste of this plant, whose odor, when fresh, is likewise very powerful, but refreshing. In the mouth it produces a pungent sensation, followed by a sense of coolness and numbness, increased by inhaling strongly. The essential oil occasions this feeling more sensibly, as well as a diffusive warmth in the abdomen, when it is swallowed. The action of peppermint is mainly that of a carminative stimulant, with a certain degree of anodyne power, which last is especially recognized by the popular use of the bruised fresh leaves to ally *colic*, *headache*, and other local pains. A hot infusion is commonly employed to relieve *colic*, *flatulence*, *diarrhœa*, *vomiting*, *cholera morbus*, *dysmenorrhœa*, and the associated abdominal pains. Nervous *headaches*, *palpitation of the heart*, *hiccup*, and other phenomena of difficult digestion, are palliated by this medicine. The hot or warm infusion, especially of the fresh herb, is a very excellent preparation; but usually the spirit is more convenient, given in sweetened hot water. The special virtues of the oil are described elsewhere.

MENTHA VIRIDIS, *U. S.*—SPEARMINT.

Herba menthæ acutæ (vel romanæ).—*Menthe verte*, *Menthe romaine*, *Baume vert*, Fr.; *Grüne Minze*, *Römische Minze*, G.

The leaves and tops of Mentha viridis, *Lin.*, s. M. sylvestris var. glabra, *Koch.* Bentley and Trimen, Med. Plants, 202.

Nat. Ord.—Labiatæ, Satureieæ.

Origin.—Spearmint is a perennial herb with a square green or sometimes purplish stem about three feet high, and multiplying extensively by long runners. It is probably a cultivated variety of *M. sylvestris*, Lin., the typical form of which has broader woolly leaves and a cylindrical or subconical inflorescence, and is frequently found in moist and swampy localities throughout the greater portion of Europe. Spearmint appears to be indigenous to England, but it is cultivated, and has been naturalized, in the United States and most civilized countries. It flowers from July to September.

Description.—The leaves are sessile, or only the lowest with a very short petiole, two to three inches long, lanceolate to ovate-lanceolate, acute, serrate, smooth, or sparingly hairy, and densely glandular beneath. The inflorescence is in terminal, narrow acute spikes, with distant whorls of about fifteen to twenty flowers in each. The glandular calyx is tubular bell-shaped, with five sharp and ciliate teeth; the corolla is light-purplish, naked, four-lobed, and bears upon its tube four long and nearly equal stamens. Spearmint has a strong aromatic odor and a warm aromatic taste, which resembles that of peppermint, but is less pungent.

The German and other Pharmacopœias recognize, instead of spearmint, the so-called *crisped mint*, *Mentha crispa*, Lin., which is a cultivated variety of *M. aquatica*, Lin. Other species of mint, like *M. sylvestris*, *viridis*, *sativa*, and *rotundifolia*, Lin., frequently produce in cultivation forms with crisped leaves, and the crisped mints cultivated in different parts of continental Europe probably belong to several of these species.

Constituents.—The principal constituent of spearmint is volatile oil (see Ol. menthæ viridis); the others are of no medicinal or pharmaceutical importance.

Off. Prep.—Aqua menthæ viridis, Spiritus menthæ viridis, *U. S.*

Medical Uses.—Spearmint is generally described as identical in its action with peppermint, but it is really much less intense. Its uses are the same as those of peppermint, but its milder action has led to its being preferred for infantile cases.

MENYANTHES.—BUCKBEAN.

Folia (Herba) trifolii fibrini, P. G.—*Bogbean, Marsh trefoil*, E.; *Ményanthe, Trèfle d'eau (de marais)*, Fr.; *Fieberklee, Bitterklee, Dreiblatt*, G.

The leaves of Menyanthes trifoliata, *Lin.* *Nat. Ord.*—Gentianaceæ.

Origin.—The buckbean is a perennial, indigenous to North America from Pennsylvania northward, to Europe and Northern Asia. It grows in boggy places, has a fleshy rhizome of the thickness of a finger, and sheathed by the remnants of the leaf-stalks, and bears a naked scape with about fifteen rose-colored or whitish flowers. It blooms in May and June.

Description.—The leaves are on petioles, four or six inches long, ternate, the leaflets sessile, about two inches long, obtuse, oblong or obovate, the margin slightly crenate, smooth, and pale green. They are inodorous, and have a very bitter taste free from astringency.

Constituents.—Trommsdorff found in the leaves the principles usually present in herbaceous parts of plants, and obtained the bitter principle in the form of an extract-like mass. Brandes (1830 and 1842) succeeded in gaining it partly as a thick amorphous mass, partly in yellowish-white granules. Landerer (1839) found an ethereal extract of buckbean to contain white bitter needles, which were soluble in water and alcohol, and precipitated by alkalies from their acid solution (?). Kromayer and Ludwig (1861) obtained *menyanthin*, which has probably the composition $C_{33}H_{54}O_{16}$, by several processes. The following is an outline of one of them: The concentrated infusion is precipitated with tannin, the precipitate mixed with litharge, dried, and exhausted with alcohol. The mass left on evaporating the alcohol is washed with cold water and ether, again treated as before with tannin and litharge, the alcoholic solution passed through animal charcoal, mixed with water, and evaporated. It dries over sulphuric acid to an amorphous whitish mass, which, on the application of heat, softens, and at 115° C. (239° F.) is limpid and transparent. It is sparingly soluble in cold water, soluble in alkalies and alcohol, but insoluble in ether. It has a very bitter taste, aud when boiled with dilute acids is resolved into sugar, a brown resin, and *menyanthol*, the latter being oily, volatile, heavier than water, and of an agreeable odor resembling that of bitter almonds.

Pharmaceutical Uses. EXTRACTUM MENYANTHIS S. TRIFOLII FIBRINI.—The French preparation is the inspissated juice. In Germany it is made by hot infusion of the dry leaves with water.

Medical Action and Uses.—Water-shamrock, or marsh trefoil, is a bitter tonic which is reputed to be also antiscorbutic, emmenagogue, and vermifuge. In large doses, like other bitters, it acts as an emetic, and some observers have attributed to it narcotic qualities. It is chiefly used in atonic *dyspepsia* and those hepatic and digestive derangements which are apt to prevail in damp malarial localities. It is a popular remedy in chronic *cutaneous eruptions* both internally and externally. The most efficient form of the medicine is the expressed juice, which is administered in the dose of two or three ounces daily, in whey or thin broth. A decoction is made with half an ounce of the herb in a pint of water, both for internal and external use.

MESEMBRYANTHEMUM.—ICE PLANT.

Diamond fig, E.; *Glaciale*, *Cristalline*, Fr.; *Eiskraut*, G.

Mesembryanthemum crystallinum, *Lin.* *Nat. Ord.*—Mesembryanthemeæ.

Description.—The ice plant is an annual or biennial, growing near the sea-coast of Southern Europe and Southern Africa, and is much cultivated for ornament. It is smooth, but covered with glittering vesicles resembling hoar-frost, about a foot long, decumbent; has the lower leaves opposite, the upper ones alternate, varying between roundish-ovate or obovate to oblong, wavy, amplexicaul, and frequently purplish on the margin and apex. The flowers are nearly sessile, white or reddish, have numerous linear petals and stamens, and produce a five-celled many-seeded capsule. The plant is inodorous, and has an unpleasant saline taste.

Constituents.—John found the expressed juice to contain 3 per cent. of solid matter, consisting of various salts and the ordinary principles of the herb. The liquid of the vesicles, according to Voelcker, contains albumen, oxalic acid, and various salts. The dry plant yielded to Brandenburg 42 per cent. of ash, of which 31 per cent. were sodium salts, the remainder being salts of earths and traces of potassium.

Medical Action and Uses.—This is an obsolete medicine, which once had a certain vogue in Europe, especially for the relief of disorders of the bladder attended with *dysury* or *incontinence* of urine. The expressed juice was used in the *dose* of a tablespoonful daily.

MESENNA.—MUSENNA.

Muséna, *Moucéna*, Fr.; *Musennarinde*, G.

Origin.—The musenna bark has been referred by Brogniart to a papilionaceous tree, *Albizzia anthelmintica*, and by Martius, Hochstetter, and others to *Rottlera Schimperi*, *Nat. Ord.* Euphorbiaceæ. The bark comes from Abyssinia, and was sent to Europe about the year 1838.

Description.—Musenna bark comes in flat or bent pieces, which are one or two inches broad and sometimes twelve inches long. The outer surface is either smooth and brown-gray, or uneven, fissured, and yellowish-brown, followed by a thick pale brownish-yellow granular layer, which covers the very tough and fibrous bast layer. The bark is inodorous, and has, particularly in the liber, a nauseous, sweet, bitterish, and afterwards persistently acrid taste.

Constituents.—Thiel (1862) isolated *musennin*, which is an amorphous acrid principle resembling saponin, but more soluble than this in alcohol; the bitter principle has not yet been obtained pure. Tannin appears to be absent. The bark yields 5½ per cent. of ash, containing much silica.

Medical Action and Uses.—It is alleged that the Abyssinians, to expel the *tænia*, use three or four ounces of the powdered bark of musenna made into an electuary, after fasting for twenty-four hours. The parasite is discharged, neither whole nor in fragments, but reduced to a sort of pulp. The medicine thus administered is apt to occasion nausea, but neither colic nor diarrhœa, and its use is followed after several hours by a purgative, usually of castor oil.

METHYLENI BICHLORIDUM.—BICHLORIDE OF METHYLENE.

Chloro-methyl, E.; *Chlorure de méthyle monochloré, Éther chlorhydrique monochloruré de l'esprit de bois*, Fr.; *Methylenchlorid, Chlormethylchlorür*, G.

Formula CH_2Cl_2. Molecular weight 85.

Preparation.—Methyl chloride (CH_3Cl) is prepared by heating a mixture of one part of methylic alcohol, two parts of common salt, and three parts of sulphuric acid, and passing the gas through water into a glass globe, into which chlorine gas is conducted at the same time; the globe is drawn out below so as to form a thin tube, which passes into one tubulure of a Woulfe's bottle, the second tubulure being connected, by means of a bent glass tube, with a second Woulfe's bottle placed in ice, and this with a flask, cooled by means of a freezing mixture; the liquid condensed in the Woulfe's bottles is chiefly chloroform, while that condensing in the flask will be pure methylene bichloride. This is Regnault's process, by whom the compound was discovered (1840), while methyl chloride was discovered by Dumas and Peligot (1835).

Properties.—Methylene bichloride is a colorless liquid, having at 18° C. (64.4° F.) the spec. grav. 1.344, and boiling at 30.5° C. (87° F.). Its odor resembles that of chloroform. It has no action upon test-paper, is soluble in alcohol and ether, and scarcely affected by alcoholic solution of potassa. Its vapor has the density 3.012, and burns with a bright flame.

In composition it may be regarded as a chloride of methylene (CH_2), or as a derivative of methyl, CH_3; the following shows its relation to allied compounds:—

	Methyl CH_3.	Methylene CH_2.
Marsh gas	$CH_3.H$	——
Methyl chloride	$CH_3.Cl$	——
Methylene bichloride . . .	$CH_2Cl.Cl$	CH_2Cl_2
Chloroform	$CHCl_2.Cl$	$CHCl.Cl_2$
Chloro-carbon	$CCl_3.Cl$	$CCl_2.Cl_2$

Physiological Action. *On Animals.*—Dr. Richardson found that chloride of methylene produced, though in a less intense degree, the same effects as the bichloride, which has the great advantage of being a more stable compound. When pigeons are exposed to the vapor of this latter preparation, it is longer in producing anæsthesia than chloroform, the pulse and respiration are more accelerated, the insensibility more prolonged, and the recovery more sudden. In a rabbit killed by it the heart-beat and the breathing ceased simultaneously; the lungs were not congested, and both sides of the heart contained blood. Blood saturated with this bichloride is of a bright red color, and even when defibrinated forms a clot of albumen and corpuscles.

On Man.—The inhalation of the vapor is described as being very pleasant and but slightly irritating; drowsiness and unconsciousness coming on without any noise in the head or oppression, and recovery taking place at once and completely, without any sense of depression. Like chloroform, it is very apt to occasion vomiting; and like ether, it sometimes causes a stage of excitement and struggling which may be difficult to subdue. Although it does not produce fatal effects as frequently as chloroform, it is not wholly exempt from that danger. Up to 1874 at least four cases had been reported in which death was directly traceable to this anæsthetic, and in the following year a fifth occurred in London. In the last case the breathing became suddenly loud and stertorous, deep, full, and exaggerated; the lips and cheeks retained their color; the pulse at the wrist failed rapidly, and then ceased almost suddenly. A sixth case occurred at Ipswich, England, in which the stertor was preceded by rather violent struggling.

Surgical Uses.—In 1877 Mr. Spencer Wells made the following statement, which, in relation to the particular class of cases referred to, appears conclusive as to the superiority of this anæsthetic: "In 1872 I made known my opinion that all the advantages of complete anæsthesia with fewer drawbacks could be obtained better by the use of bichloride of methylene than by any other known anæsthetic. This was the result of the experience of five years, and of three hundred and fifty serious operations. The experience of the five succeeding years, with more than six hundred additional cases of ovariotomy, and many other cases of surgical operations, has fully confirmed me in this belief. Given properly diluted with air, it has, in my experience of ten years, with more than one thousand operations of a nature unusually severe as tests of an anæsthetic, proved to be, without a single exception, applicable to every patient, perfectly certain to produce complete anæsthesia, relieving the surgeon from all alarm and even anxiety; and its use has never been followed by any dangerous symptoms which could be fairly attributed to it." Other surgeons have testified to its efficiency in a great variety of surgical operations, both capital and trivial; yet, from whatever cause, it does not seem to have supplanted, to any great extent, either chloroform or ether. Perhaps it may be, as Mr. Wells remarks, that the fluid sold as bichloride of methylene may have been only chloroform mixed with some spirit or ether; perhaps the reason may be found in the opinions expressed by Dr. Richardson himself, that "he was not favorably impressed with the application of the bichloride to *quick* general anæsthesia," and that "it belongs to a dangerous family of chemical substances, and cannot therefore be played with without risk."

The deaths above referred to have been attributed to asphyxia, but their symptoms distinctly refute that opinion; yet it is none the less imperative that in administering the vapor a sufficient proportion of atmospheric air should be admitted along with it. For this purpose a hollow cone made of pasteboard, pierced with holes, should contain the cloth or sponge upon which the liquid has been poured. The quantity used should not exceed, for a first inhalation, thirty or forty minims; half that quantity may be used each time that signs of returning consciousness appear.

METHYLI IODIDUM.—IODIDE OF METHYL.

Iodure de methyle, Fr.; *Jodmethyl*, G.
Formula CH_3I. Molecular weight 142.

Preparation.—This compound was first obtained by Dumas and Peligot (1835) by adding very gradually 1 part of phosphorus to a solution of 8 parts of iodine in 12 or 15 parts of methylic alcohol, agitating the distillate with water, and rectifying. According to Wanklyn (1867), iodide of potassium and anhydrous methylic alcohol are mixed in a retort in equivalent proportions; dry chlorine gas is passed into the mixture, which is then distilled, and the distillate purified as before.

Properties.—Iodide of methyl is a colorless liquid of an ethereal odor, and the spec. grav. 2.199 at 0° C. (32° F.). It boils at 43.8° C. (111° F.), and by the aid of a wick burns with difficulty, giving off violet vapors.

Allied Compound.—METHYLENII IODIDUM, s. biniodidum CH_2I_2 (mol. weight 268) was prepared by Butlerow (1859), by acting upon iodoform with sodium ethylate. It is readily formed by heating chloroform with very concentrated hydriodic acid for several hours to near 130° C. (266° F.). It is a yellow liquid, having the spec. grav. 3.34, congealing to glossy scales near the freezing point, and boiling at 180° C. (356° F.), at the same time suffering partial decomposition.

Medical Action and Uses.—Proposed in 1868 by Dr. B. W. Richardson, iodide of methyl was stated to be respirable and anæsthetic when pure; but when decomposed, as it was apt to become, to give rise to the irritating effects of iodine, including lachrymation, salivation, and bronchial secretion. In experiments upon animals inhalation of the vapor produced fatal engorgement of the bronchia. Of it Sir James Y. Simpson wrote: "I found it very powerfully anæsthetic, but dangerously so. After inhaling a very small quantity for two or three minutes, I remained for some seconds without feeling much effect; but objects immediately began to multiply before my eyes, and I fell down in a state of insensibility, which continued for upwards of an hour. I did not completely recover from the effects of it for some days." It was used as a local anæsthetic in cancerous and other cases; but it appears at present to have become obsolete.

MEZEREUM, *U. S.*—MEZEREON.

Mezerei cortex, Br.; *Cortex mezerei*, P. G.; *Cortex thymeleæ (vel coccognidii)*.—*Mezereon bark*, E.; *Écorce de mézéréon, de garou, de lauréole, de thymélée*, Fr.; *Seidelbastrinde, Kellerhalsrinde*, G.

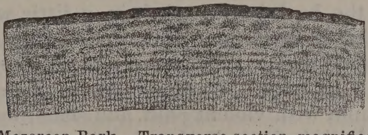
The bark of Daphne mezereum, *Lin.;* Daphne gnidium, *Lin.;* and Daphne laureola, *Lin.* Steph. and Church, Med. Bot., plate 65; Eng. Bot., vol. ii., plate 119; Bentley and Trimen, Med. Plants, 225, 226, 227.

Nat. Ord.—Thymelaceæ.

Origin.—The three plants named above are small shrubs about 2 to 4 feet high. The mezereon has rose-red, sessile, fragrant flowers in small clusters, preceding the deciduous leaves, and is indigenous to hilly and mountainous regions of Europe, extending to the arctic circle, and eastward to Siberia. The other two species are found in Southern Europe; D. laureola, or *spurge laurel*, is also met with eastward to Asia Minor. This species has large evergreen leaves and yellowish-green flowers in axillary clusters, while the *spurge flax* (D. gnidium) has narrow annual leaves and small white flowers in terminal, corymbose racemes. The bark is usually collected during the winter.

Description.—Mezereon bark is in long bands, about ½ inch wide, $\frac{1}{20}$th of an inch and less thick, either folded and tied together in bundles, or rolled up into flat disks, with the inner surface outwards. The outer surface varies in color from pale-yellowish or brownish to brown-yellow, with a coppery lustre, and is marked with numerous minute blackish warts and transversely elongated leaf-scars, in the axils of which is found a cluster of blackish spots. Older bark shows some transverse fissures. The corky layer is easily separated from the pale greenish outer bark. The inner surface is whitish, of a silky lustre, and from loosened bast fibres has a hairy appearance. The bark tears somewhat irregularly in a longitudinal direction, but with difficulty transversely. The fine and tough bast fibres are in tangential rows, and alternate with layers of

Fig. 109.



Mezereon Bark.—Transverse section, magnified.

parenchyma. The dried bark is inodorous, and has a persistently acrid and burning taste.

The bark of the spurge flax is of a darker brown color, and has numerous spirally arranged leaf-scars; that of the spurge laurel is more of a gray or brown-gray color, not prominently marked with leaf-scars, and has a greenish bast; both agree with mezereon bark in acridity. The root bark of the three species is regarded as the strongest, but the stem bark is most generally met with.

Constituents.—Landerer observed (1836) that mezereon bark contains a neutral acrid principle which volatilizes with the vapors of water; a similar observation was made by Squire (1842) with mezereon root; and by Vauquelin (1808) with the distillate from water which had been used for washing the resin. The acrimony is, however, mainly due to a soft resin or oil, which, according to C. G. Gmelin (1822), is not precipitated by lead acetate from its alcoholic solution. This acrid principle deserves further investigation. Vauquelin (1808) discovered *daphnin* in the bark of spurge flax, and the same principle was isolated by Gmelin and Bär (1822) from mezereon bark. Rochleder (1864) obtained it from the aqueous decoction of the alcoholic extract, after precipitating with sugar of lead, by precipitating it with subacetate of lead, decomposing with hydrogen sulphide, washing with ether, and crystallizing from water. It has a persistently bitter, not acrid, taste, dissolves readily in hot water and alcohol, is insoluble in ether, yields with alkalies yellow solutions, and colors ferric chloride blue. Zwenger (1860) ascertained it to be a glucoside of the composition $C_{31}H_{34}O_{19}.4H_2O$, yielding *daphnetin* $C_{19}H_{14}O_9$, which has a coumarin-like odor. On the dry distillation of the alcoholic extract *umbelliferon* is obtained.

Pharmaceutical Uses.—The comminution of the bark requires some precaution to avoid the injurious effects of the dust. The bark may be readily cut into small pieces, and should then be moistened with a little water, which should also be added on bruising the bark in a mortar.

Off. Prep.—Decoct. sarsaparillæ (sarsæ) comp., *U. S.*, *Br.;* Extr. mezerei æthereum, *Br.;* Extr. mezerei fluid., Extr. sarsaparillæ compos. fluid., *U. S.*

Physiological Action.—Ancient and modern authorities agree in describing the various conditions which mezereon is fitted to cure. They all imply the possession by the medicine of irritant qualities; thus we learn that it irritated the fauces, and was capable of reddening, and even of blistering, the skin; that it was used as a gargle in sore-throat, and as an emetic, purgative, cholagogue, emmenagogue, and sudorific. All of these effects agree with the view that it is essentially an irritant. Experiments on animals prove it to be a violent irritant of the gastro-intestinal mucous membrane, and observations upon man lead to the same conclusion. In some of the latter there was narcotism or convulsions, and, in one at least, acrid and blood-red urine. Death has sometimes ensued. When the bark is chewed, it in a little while excites a burning heat in the mouth, which lasts for many hours. In medicinal doses the decoction causes salivation and increased cutaneous and mucous secretions, which are said to acquire a peculiar odor. Excessive doses give rise to symptoms of gastro-intestinal irritation, with violent pain, and sometimes very severe urinary irritation. When the bark is fresh, or has been soaked in water or in vinegar, it reddens the skin, and at length occasions vesicles, followed by moist and painful ulcers which are difficult to heal. A case is recorded of a girl upon whose cheek the fresh juice of mezereon had been rubbed. Extreme swelling, pain, and a vesicular eruption were followed by fever and internal disorders, which are said, after the lapse of nine months, to have ended fatally.

Medical Uses.—At one time mezereon was much in vogue as a remedy for *syphilis*, and to this day it is an ingredient of the compound decoction of sarsaparilla. But the evidence in its favor is not adapted to convince. In chronic, non-syphilitic, *cutaneous diseases*, its reputation was equally ill-founded.

In *chronic rheumatism* it seems to have been more useful; but here, also, its real value in a complex system of treatment is difficult to determine. It is seldom used alone, except as a *local irritant*, in the form of the recent or moistened bark above referred to. In this respect it may more or less take the place of cantharides, or be employed to prolong the action of the latter. It has been applied to improve the condition of foul or indolent *ulcers*, and to maintain the discharge from *issues* and *setons*. For these purposes mezereon ointment is convenient. To excite vesication the bark, prepared as above described, and bound firmly to the skin with a roller, should be freshly applied twice every day, until vesication begins. Mezereon ointment may be used to prolong and renew the suppuration originally produced by cantharides.

When poisoning by mezereon occurs, the stomach should be evacuated by lukewarm, albuminous, or mucilaginous liquids. Milk and fatty oils may also be administered.

MICA PANIS, *Br.*—CRUMB OF BREAD.

Mie du pain, Fr.; *Brodkrumen*, G.

The soft part of bread made with wheat flour.

It is employed as an excipient in the preparation of certain pills, like those of corrosive sublimate, etc., and externally for emollient poultices. It is a constituent of *Cataplasma carbonis*.

Medical Uses.—It is to be presumed that this article was made officinal, in order that only wheaten bread should be used. But in the only article for which it is directed, charcoal poultice, any other form of bread would answer equally well. In this country Indian corn meal is generally employed. Bread crumb is sometimes used for making pills.

MISTURÆ vel MIXTURÆ.

Mixtures, E., Fr.; *Mixturen*, G.

Liquid medicines which contain insoluble substances in suspension, or which are composed of two or more liquids, with or without the addition of saline or other material, are termed mixtures, and in its more limited application the term is restricted to mixtures intended for internal use. They are most frequently prepared extemporaneously and upon the prescriptions of physicians, since even among the officinal ones but few possess sufficient stability to permit them to be kept on hand for a longer period than a few days. Insoluble substances, when light and readily diffusible in water, do not generally require the addition of gum arabic or other mucilaginous body to insure their uniform suspension and the equalization of the dose; such an addition is desirable in all cases where the insoluble bodies are much heavier than water. However, some judicious restrictions are necessary, lest the insoluble compound form a compact deposit which cannot be readily suspended again by agitation. This difficulty may be avoided by reducing the gum to a very small proportion, and increasing the suspending power of the vehicle by the addition of sugar or glycerin. When fats, volatile oils, or resinous substances are to be given in watery liquids, gum or the yolk of egg is requisite as a medium for uniform, and within certain limits permanent suspension; such mixtures are opaque, and are called *emulsions*. Certain drugs, like the gum-resins and some seeds, naturally contain a principle (gum, emulsin, etc.), which is capable of keeping the oil or resin suspended in water, and when triturated with water yield emulsions; in all cases the drug should be rubbed or beaten into a uniform pasty mass, if necessary, with small quantities of water, the trituration being afterwards continued with the gradual addition of water, after which the emulsion may be strained. Unglazed wedgewood or porcelain mortars having a rather flat bottom are very serviceable for this purpose. Under no circumstance should powdered gum resins be employed, unless they have been powdered and sifted in cold weather, without having been previously dried by heat.

Fixed oils, to be emulsified, require as a rule one-half their weight of powdered gum arabic, and the mixture may then be diluted with water to eight or ten times the quantity of oil employed. We have been informed by Mr. Boring that the employment of the officinal infusion or syrup of wild cherry materially facilitates the perfect suspension of oils. To prepare emulsions the powdered gum is triturated with not over 1½ times its weight of water, the oil is gradually added, each portion being completely emulsified before more is added. Or the oil and gum are well mixed together, 1½ parts of water for one of gum is added at once and well triturated; when uniform, the remaining water may be incorporated. Dilg (1878) succeeded in making permanent emulsions by using gum arabic equal to one-eighth the weight of the oil; the powdered gum, one part, is at once made into a thin mucilage, with four parts of water, the oil is then mixed with it gradually, and when these are well combined, four parts of water are added in small portions and with constant trituration, after which the mixture will bear copious dilution with water. If properly made, the oil will not separate, and if, after several days, a cream-like layer should rise to the surface, it may be readily incorporated with the aqueous liquid by agitation. For the proper emulsion of solid fats, and if not inadmissible, also of camphor and resins, the addition of almond or similar fixed oil is advisable, but not indispensable. A yolk will readily emulsionize an ounce of fixed oil, and facilitate the suspension of resins and volatile oils; the latter require a larger amount of gum than the fats, unless the process of J. W. Forbes (1872) be followed, who directs for one ounce of volatile oil, ether, or chloroform, only twenty grains of gum arabic. The liquid to be emulsionized is first introduced into a vial, and then the gum; the two are well mixed by agitation; half an ounce of water is added and thoroughly incorporated by agitation, after which the mixture is diluted with the remaining water or mucilage. On standing, a denser emulsion separates like cream, which is again readily mixed on slight agitation. In applying this process to fixed oils, E. Gregory (1876) found it necessary to increase the powdered acacia to three-eighths the weight of the oil.

Emulsio oleosa of European pharmacy is prepared with two parts of expressed oil of almonds, one part of powdered acacia, and seventeen parts of water.

MISTURA AMMONIACI, *U. S.*, *Br.*—AMMONIAC MIXTURE.

Emulsio ammoniaci, *Lac ammoniaci.*—*Ammoniacum mixture*, *Milk of ammoniac*, E.; *Mixture de gomme ammoniaque*, *Lait ammoniacal*, Fr.; *Ammoniak-Emulsion*, G.

Preparation.—Take of Ammoniac one hundred and twenty grains; Water half a pint. Add the water gradually to the ammoniac, rubbing them together until they are thoroughly mixed, and strain. *U. S.*

Take of Ammoniacum in coarse powder a quarter of an ounce; Distilled Water eight fluidounces. Triturate the ammoniacum with the water, gradually added, until the mixture assumes a milky appearance; then strain through muslin. *Br.*

Medical Uses.—Mixture of ammoniac is employed chiefly in the treatment of *chronic bronchitis* and *bronchorrhœa*. The *dose* is one or two tablespoonfuls.

MISTURA AMYGDALÆ, *U. S.*, *Br.*—ALMOND MIXTURE.

Emulsio amygdalæ, s. amygdalarum; Emulsio simplex.—Milk of almonds, E.; *Emulsion simple, Lait d'amandes,* F.; *Mandelmulsion, Mandelmilch,* G.

Preparation.—Take of Sweet Almond half a troyounce; Gum Arabic in fine powder thirty grains; Sugar one hundred and twenty grains; Distilled Water eight fluidounces. Having blanched the almond, add the gum arabic and sugar, and beat them in a mortar until they are thoroughly mixed; then rub the mixture with the distilled water gradually added, and strain. *U. S.*

Take of Compound Powder of Almonds two and a half ounces; Distilled Water one pint. Rub the powder with a little of the water into a thin paste, then add the remainder of the water, and strain through muslin. *Br.*

The presence of gum arabic in both preparations does not increase the stability of either, or the amount of oil suspended. European physicians sometimes prescribe *compound emulsion of almonds*, for which the German Pharmacopœia gives the following directions:—

Emulsio amygdalarum composita: Take of Sweet Almonds four parts; Hyoscyamus Seed one part; Diluted Bitter Almond Water sixty-four parts. Make an emulsion, and add of white sugar six parts; calcined magnesia one part.

Medical Uses.—Almond mixture is an excellent demulcent in *acute laryngeal* and *bronchial* inflammations, *dysentery*, and irritations of the *urinary passages.* It should be administered freely.

MISTURA ASSAFŒTIDÆ, *U. S.*—ASAFŒTIDA MIXTURE.

Mistura (Lac) asafœtidæ.—Milk of asafœtida, E.; *Mixture (Lait) d'asafœtida,* Fr.; *Asafœtida-Emulsion, Stinkasantmilch,* G.

Preparation.—Take of Asafetida one hundred and twenty grains; Water half a pint. Add the water gradually to the asafetida, and rub them together until they are thoroughly mixed. *U. S.*

A *syrup of asafœtida*, of the same strength as the mixture, may be prepared by triturating one hundred and twenty grains of selected tears with small quantities of water, decanting the concentrated emulsion until four fluidounces are obtained, in which six troyounces of sugar are dissolved by agitation. While at first milk white, it acquires, after exposure, a pinkish color; the resin, which partially separates on standing, is easily incorporated by agitation. If desired, the asafœtida odor may be covered by the addition of a little oil of bitter almonds, or, as suggested by J. J. Rambo (1871), by substituting infusion of wild cherry bark for the water, which changes the white to a brownish color.

A *wine of asafœtida* was recommended by H. N. Rittenhouse (1855) to be made by triturating half a troyounce of the gum resin with sufficient white wine to obtain two fluidounces, one drachm of which, mixed with seven drachms of water, represents approximately the officinal mixture.

Medical Uses.—Asafœtida mixture is the most prompt and decided in its action of all the forms of administering asafœtida by the mouth. It is frequently given as an enema; but for the latter purpose a mixture of an ounce of tincture of asafœtida with half a pint of water, is more convenient and efficient. The *dose* of mixture of asafœtida is one or two tablespoonfuls.

MISTURA CHLOROFORMI, *U. S.*—CHLOROFORM MIXTURE.

Emulsio chloroformi.—*Emulsion de chloroforme*, Fr.; *Chloroform-Emulsion*, G.

Preparation.—Take of Purified Chloroform half a troyounce; Camphor sixty grains; The Yolk of one Egg; Water six fluidounces. Rub the yolk in a mortar, first by itself, then with the camphor, previously dissolved in the chloroform, and, lastly, with the water, gradually added, so as to make a uniform mixture. *U. S.*

Medical Uses.—This mixture forms a stable preparation which may sometimes be convenient for the administration of chloroform in cases of *gastralgia*, *flatulent*, *biliary*, *renal*, and *uterine colic*, and in *nervous* or *hysterical* paroxysms. The *dose* is one or two tablespoonfuls.

MISTURA CREASOTI, *Br.*—CREASOTE MIXTURE.

Mixture de créosote, Fr.; *Kreosot-Mixtur*, G.

Preparation. — Take of Creasote, Glacial Acetic Acid, each sixteen minims; Spirit of Juniper half a fluidrachm; Syrup one fluidounce; Distilled Water fifteen fluidounces. Mix the creasote with the acetic acid, gradually add the water, and lastly the syrup and spirit of juniper. *Br.*

Medical Uses.—Creasote mixture, it is stated, is intended to allay *vomiting;* but the bulk of its dose, and the spirit of juniper and syrup contained in it, render it peculiarly unfit to relieve the cases of vomiting in which creasote is most useful. The purpose of the glacial acetic acid in this mixture is not evident. The officinal *dose* is stated to be from one to two ounces.

MISTURA CRETÆ, *U. S.*, *Br.*—CHALK MIXTURE.

Mixture avec la craie, Fr.; *Kreidemixtur*, G.

Preparation.—Take of Prepared Chalk half a troyounce; Glycerin half a fluidounce; Gum Arabic in fine powder one hundred and twenty grains; Cinnamon Water, Water, each four fluidounces. Rub the chalk and gum arabic with the water, gradually added; then add the other ingredients, and mix the whole together. *U. S.*

Take of Prepared Chalk quarter of an ounce; Gum Acacia in powder quarter of an ounce; Syrup half a fluidounce; Cinnamon Water seven and a half fluidounces. Triturate the chalk and gum acacia with the cinnamon water, then add the syrup, and mix. *Br.*

The substitution of glycerin for sugar in the first process is in accordance with the recommendation of G. W. Kennedy (1872), and it renders the mixture more permanent.

Medical Uses.—Chalk mixture is one of the most convenient forms in which chalk can be administered in the *diarrhœas* both of adults and children, especially when the discharges are yeasty or greenish, and there is flatulent distension of the abdomen, with sour eructations. If there is reason to suspect the presence of undigested food in the bowels, a dose of magnesia should first be given. For the watery diarrhœa which often precedes the attack of *epidemic cholera*, there is no better medicine than this. In most cases laudanum should be added to the mixture, or given along with it; and ordinarily its efficiency is much increased by the addition of kino, krameria, or catechu.

MISTURA FERRI AROMATICA, *Br.*—AROMATIC MIXTURE OF IRON.

Mixture de fer aromatique, Fr.; *Aromatische Eisenmixtur*, G.

Preparation.—Take of Pale Cinchona Bark in powder one ounce; Calumba Root in coarse powder half an ounce; Cloves bruised one-quarter ounce; Fine Iron Wire half an ounce; Compound Tincture of Cardamoms three fluidounces; Tincture of Orange Peel half a fluidounce; Peppermint Water a sufficiency. Macerate the cinchona bark, calumba root, cloves, and iron with twelve fluidounces of the peppermint water in a closed vessel for three days, agitating occasionally; then filter the liquid, adding as much peppermint water to the filter as will make the product measure twelve and a half fluidounces; to this add the tinctures, and preserve the mixture in a well-stopped bottle. *Br.*

This has been introduced into the British from the old Dublin Pharmacopœia. During the maceration a portion of the iron is dissolved by the organic acids contained in the drugs.

Medical Uses.—This is a mixture of bitter tonics and aromatic stimulants with a modicum of iron. Many years ago it was appropriately described by Neligan, who said: "In consequence of its black color it is commonly known as *Heberden's ink*. Notwithstanding its being an unchemical compound, it is a most excellent tonic; it is very generally used in Dublin, in the various states of debility attended with anæmia. *Dose*, from one to two fluidounces."

MISTURA FERRI COMPOSITA, *U. S.*, *Br.*—COMPOUND MIXTURE OF IRON.

Griffith's mixture, E.; *Mixture de Griffith*, Fr.; *Griffith's Eisenmixtur*, G.

Preparation.—Take of Myrrh, Sugar, each sixty grains; Carbonate of Potassium twenty-five grains; Sulphate of Iron in coarse powder twenty grains; Spirit of Lavender half a fluidounce; Rose Water seven fluidounces and a half. Rub the myrrh, sugar, and carbonate of potassium, with the rose water, gradually added, then with the spirit of lavender, and, lastly, with the sulphate of iron; and pour the mixture immediately into a bottle, which must be well stopped. *U. S.*

Take of Sulphate of Iron twenty-five grains; Carbonate of Potash thirty grains; Myrrh, Refined Sugar, each sixty grains; Spirit of Nutmeg four fluidrachms; Rose Water nine and a half fluidounces. Reduce the myrrh to powder, add the carbonate of potash and sugar, and triturate them with a small quantity of the rose water, so as to form a thin paste; then gradually add more rose water and the spirit of nutmeg, continuing the trituration and further addition of rose water until about eight fluidounces of a milky liquid is formed, then add the sulphate of iron dissolved in the remainder of the rose water, mix them together thoroughly, and preserve the mixture as much as possible from contact with the air. *Br.*

The preparation of this mixture presents no difficulty if good tears of myrrh are selected, and the directions are strictly followed. The reaction between the iron and potassium salts, resulting in the formation of ferrous carbonate and potassium sulphate, takes place in the myrrh emulsion, by which the insoluble ferrous carbonate is kept in suspension. Unless in full and well-corked bottles, the mixture, at first of a dirty greenish color, is hardly protected against oxidation by the small quantity of sugar present, and should be freshly made when needed.

Medical Uses.—This preparation has special advantages over other ferruginous medicines in several chronic affections, and especially in *chlorotic anæmia*, *chronic bronchitis*, *albuminuria*, and certain chronic *diseases of the skin* (eczema, psoriasis). These disorders have in common a deteriorated condition of the blood, and a debility of the nervous system, which the iron of the mixture is adapted to correct; and several among them present in addition a relaxed state of the secretory organs, which the myrrh and the sulphuric acid tend to counteract. The two first named are those which usually exhibit the most favorable results. The mixture was originally called *antihectic*, from the utility it manifested in hectical conditions of pulmonary disease; not those, however, as is sometimes erroneously supposed, which belong to tubercular consumption, but those of chronic bronchitis attended with purulent expectoration, and usually associated with dilatation of the bronchia. The *dose* is from half an ounce to an ounce and a half two or three times a day.

MISTURA GENTIANÆ, *Br.* See INFUSUM GENTIANÆ COMPOSITUM.

MISTURA GLYCYRRHIZÆ COMPOSITA, *U. S.*—COMPOUND MIXTURE OF LIQUORICE.

Brown mixture, E.; *Mixture de réglisse*, Fr.; *Lakritzen-Mixtur*, G.

Preparation.—Take of Liquorice in fine powder, Sugar in coarse powder, Gum Arabic in fine powder, each half a troyounce; Camphorated Tincture of Opium two fluidounces; Wine of Antimony a fluidounce; Spirit of Nitrous Ether half a fluidounce; Water twelve fluidounces. Rub the liquorice, sugar, and gum arabic with the water, gradually added; then add the other ingredients, and mix the whole together. *U. S.*

The mixture has a turbid and unsightly appearance, from the presence of the insoluble matters contained in powdered extract of liquorice. An equally efficient and much handsomer mixture is obtained by using *purified* extract of liquorice (see page 571).

Medical Uses.—Compound liquorice mixture, or *brown mixture* as it is frequently called, is an agreeable and efficient remedy in the early stages of *acute bronchitis* and catarrhal *laryngitis*. It hastens and promotes expectoration, chiefly by reducing the febrile tension of the vascular system. The average *dose* for an adult is a tablespoonful.

MISTURA GUAIACI, *Br.*—GUAIACUM MIXTURE.

Emulsio resinæ guaiaci.—*Emulsion de resine de gaïac*, *Lait de gaïac*, Fr.; *Guajak-Emulsion*, G.

Preparation.—Take of Guaiacum Resin in powder, Refined Sugar, each half an ounce; Gum Acacia powdered one-quarter ounce; Cinnamon Water one pint. Triturate the guaiacum with the sugar and the gum, adding gradually the cinnamon water. *Br.*

This is a partial emulsion of guaiac resin, which, on exposure, soon changes in color (see page 684).

Medical Uses.—Although unpleasant to the taste, it is perhaps less repulsive than the tinctures of guaiac. Very probably, also, the guaiacum in it being thoroughly divided by sugar and gum is more readily acted upon and absorbed by the stomach than the solid mass precipitated from a tincture would be. *Dose*, from one to four tablespoonfuls several times a day.

MISTURA POTASSII CITRATIS, *U. S.*—MIXTURE OF CITRATE OF POTASSIUM.

Mistura neutralis.—Neutral mixture, E.

Preparation.—Take of Lemon Juice, fresh, half a pint; Bicarbonate of Potassium a sufficient quantity. Add the bicarbonate of potassium gradually to the lemon juice until the acid is completely neutralized; then strain through muslin. *U. S.*

In composition this mixture is identical with Liquor potassii citratis (p. 849), but being prepared with fresh lemon juice is aromatic and more agreeable. The juice should be strained before the bicarbonate is added, to avoid the expulsion of the carbonic acid gas by subsequent straining.

Medical Uses.—Neutral mixture is diaphoretic and diuretic. It is very generally employed as a febrifuge, either alone or with the addition of antimonial wine, of spirit of nitric ether, of morphia, or of all united. It should be administered diluted with water, or, where no contraindication exists, with lemonade. The *dose* is a tablespoonful.

MISTURA SCAMMONII, *Br.*—SCAMMONY MIXTURE.

Emulsio purgans cum scammonia, Lac scammonii.—Emulsion purgative avec la scammonée, Mixture de scammonée, Fr.; *Scammonium-Emulsion*, G.

Preparation.—Take of Resin of Scammony four grains; Milk two fluidounces. Triturate the resin of scammony with a little of the milk, and continue the trituration, gradually adding the remainder of the milk, until a uniform emulsion is obtained. *Br.*

Scammony resin is readily emulsionized with milk. The French Codex directs 1 part of the resin to be first triturated with 15 parts of sugar, afterwards with 120 parts of milk, and the emulsion to be flavored with 5 parts of cherry laurel water.

Medical Uses.—Scammony forms with unskimmed milk a fine uniform emulsion, which perfectly suspends the drug, and conceals its acrid and nauseous taste. The mixture is intended to be a *dose* for an adult; for a child of five years one-third of the quantity will suffice.

MISTURA SENNÆ COMPOSITA, *Br.*

See Compound mixture of senna, under Infusum sennæ, page 757.

MISTURA SPIRITUS VINI GALLICI, *Br.*

Mixture of spirit of French wine, Brandy mixture, E.; *Mixture de cognac*, Fr.; *Branntwein-Mixtur*, G.

Preparation.—Take of Spirit of French Wine, Cinnamon Water, each four fluidounces; the Yolks of two Eggs; Refined Sugar half an ounce. Rub the yolks and sugar together, then add the cinnamon water and spirit. *Br.*

In our opinion this preparation scarcely deserves a place in a Pharmacopœia.

Medical Uses.—As a nutritious and stimulant draught this preparation is often useful in typhoid states of fever, and in exhaustion from nervous excitement, hemorrhage, and other conditions which do not contraindicate the use of alcohol. "Eggnog" made with milk is much more efficient than this preparation.

MITCHELLA.—MITCHELLA.

Partridgeberry, Checkerberry, Squawvine, Winterclover, E.

Mitchella repens, *Lin.* *Nat. Ord.*—Rubiaceæ, Cinchoneæ.

Description.—This pretty North American evergreen, which is found in woods, has a creeping and branching stem 10 to 12 inches long; opposite petiolate, roundish-ovate, entire leaves, which are about ½ inch long and often marked with white lines. The flowers are in pairs, often diœcious, have a white or pale purplish funnel-shaped corolla, and four exserted or included stamens, and produce a rather dry berry-like scarlet-red fruit, which is composed of two united ovaries, and contains four bony nutlets. The flowers are fragrant, the leaves are inodorous, somewhat astringent, and bitter.

We have no knowledge of any analysis of this plant.

Medical Action and Uses.—The virtues of this plant are exceedingly indefinite, for it is reputed to be diuretic, tonic, and astringent, and capable of facilitating child-birth if taken for several weeks before the close of pregnancy. It very probably may be useful in chronic disorders of the urinary passages, when given in decoction.

MONARDA, *U. S.*—HORSEMINT.

American horsemint, E.; *Menthe de cheval,* Fr.; *Pferdeminze,* G.

The leaves and tops of Monarda punctata, *Lin.* Bentley and Trimen, Med. Plants, 208.

Nat. Ord.—Labiatæ, Monardeæ.

Origin.—Horsemint is a perennial herb, 1 to 2 feet high, which is indigenous to the United States, where it grows in dry sandy fields from New York westward to Illinois, and southward to near the Gulf of Mexico. It flowers in the latter part of summer until September, and should be collected with the flowering tops.

Description.—The leaves are about 2 inches long, lanceolate, somewhat toothed, acute, narrowed at the base into a petiole, smooth above, glandular dotted beneath. The whorls of cymules are about 10 flowered, situated in the axils of the upper leaves, and surrounded by about 8 leafy, sessile, and entire bracts, which are pale yellow and purple in color. The tubular, downy calyx is divided into 5 short and rigid teeth. The corolla is prominent, yellowish, with the large arched upper lip spotted with purple, and a small, three-lobed, somewhat crisped lower lip. The two slender stamens are inserted in the throat above the narrow corolla tube. Horsemint has a strong aromatic odor, and a warm, pungent, somewhat bitterish taste.

Other Species of Monarda.—M. DIDYMA, *Lin.*, or *Oswego tea,* is found in the Alleghanies and northward to Canada and Wisconsin. It has the larger bracts and floral leaves tinged with red, and showy bright red corollas with the stamens exserted beyond the narrow upper lip.

M. FISTULOSA, *Lin.*, or *wild bergamot,* has the larger bracts and floral leaves of a grayish tint, and whitish or pale purplish flowers with exserted stamens; it grows in woodlands, from New England to Wisconsin southward.

Substitutions.—In some counties of Pennsylvania, *Pycnanthemum incanum,* Mich., or *wild basil, Nat. Ord.* Labiatæ, is known and popularly used as horsemint; the plant is downy to hoary, has acute, ovate, or oblong leaves, the upper ones whitened, and the flowers in dense heads with narrow linear bracts, and awned calyx lobes. In Great Britain, *Mentha sylvestris*, Lin., is known as horsemint.

Constituents.—The important constituent is the volatile oil (see Oleum monardæ), which is contained in the leaves and flowers; nothing is known about the other principles, among which are doubtless those commonly met with in herbaceous plants.

Medical Uses.—Horsemint is regarded as being diaphoretic, diuretic, carminative, and emmenagogue, like most other plants of its class containing an acrid essential oil. It may be used in hot infusion to prevent the formation of *catarrhal*, *rheumatic*, and *diarrhœal* affections occasioned by cold. The infusion is usually made with half an ounce of the herb in a pint of hot water, and may be given in wineglassful doses. The volatile oil upon which the virtues of horsemint depend is officinal. (See Oleum monardæ.)

MONESIA.—MONESIA BARK.

The bark of Chrysophyllum glyciphlœum, *Casaretti*.

Nat. Ord.—Sapotaceæ.

Origin.—The tree yielding monesia bark is indigenous to the forests of Brazil, and has alternate, coriaceous and entire leaves. The berry-like fruits of several species of Chrysophyllum are edible.

Description.—The bark is in flat or curved pieces, $\frac{1}{8}$ to nearly $\frac{1}{4}$ inch thick, often 2 or 3 inches broad, externally marked with confluent ridges, forming large irregularly quadrangular or hexagonal meshes, which are covered with a thin smooth whitish tissue while the bark is young. The inner surface is cinnamon-colored and longitudinally striate, otherwise smooth. The bark is very hard, breaks with a granular fracture, and shows in the interior alternate layers of brown and pale reddish tissue. It is inodorous, and has a peculiar taste, which is at first sweet like liquorice, afterwards bitterish, somewhat acrid and astringent.

Constituents.—Monesia bark was examined by Derosne, Henry, and Payen (1840), who announced the presence of *glycyrrhizin*, *monesin*, which appears to be identical with saponin, *tannin*, red coloring matter resembling kinic red, trace of volatile oil, pectin, 3 per cent. of ash, etc. Heydenreich (1839) separated from the aqueous extract 52 per cent. of tannin, and 36 per cent. of a sweet principle, which was not precipitated by sulphuric acid or lead acetate, and was not fermentable.

EXTRACTUM MONESIÆ, *Monesia*, comes from Brazil in irregular dark brown friable angular pieces, destitute of any red hue. It is soluble in water, and has a sweet, afterwards astringent, taste, followed by slight but persistent acridity.

Medical Action and Uses.—Internally, and in small doses, as from four to eight grains, monesia rather gives tone to the stomach, and increases the appetite; but in doses of twenty or thirty grains it occasions gastric oppression and constipation. Upon recent sores it causes a burning and stinging pain of brief duration, lessening their secretions, and promoting granulation and cicatrization. Monesin acts upon such sores as a more active irritant, inducing rapidly a plastic exudation.

The medicinal uses of monesia denote its possession of a stimulant as well as an astringent property. It has been found useful in atonic *dyspepsia*, in *vomiting* produced by atony rather than by active irritation of the stomach, and in all forms of *diarrhœa* unattended with fever. It has been employed with profit in chronic *bronchitis*, and in various forms of hemorrhage, especially *hæmoptysis* and *menorrhagia*, and locally by injection in *epistaxis*. In various ecchymoses depending upon *scurvy* its internal administration is said to have been advantageous. As a topical application it has been recommended in *ulcers* and *pseudo-membranous* exudations of the mouth and fauces, and of many other parts, also in *leucorrhœa* and *diarrhœa*, and especially in *fissures* of the *mouth* and *anus*. Although these virtues of monesia appear to have been demonstrated by clinical observation, the medicine seems to have been neglected and almost fallen into disuse.

The *dose* of monesia is stated at from three to twenty grains, or from ten to sixty grains a day. Monesin has been recommended in the dose of half a grain. For local application the tincture diluted with from ten to twenty parts of water has been used; and also an ointment made with one part of the extract to seven of lard.

MORI SUCCUS, *Br.*—MULBERRY JUICE.

Succus mororum.—*Suc de mûres*, Fr.; *Maulbeersaft*, G.

The juice of the ripe fruit of Morus nigra, *Lin.* Steph. and Church, Med. Bot., plate 39.

Nat. Ord.—Urticaceæ, Artocarpeæ.

Origin.—The black like the white mulberry, *Morus alba*, Lin., is indigenous to the Levant; both are rather small trees, about 30 feet high, and are cultivated and partly naturalized in Europe, where the leaves of both, more generally of the white, are employed for feeding the silkworm. Both species are also occasionally seen in cultivation in the United States; *M. alba*, however, is alone naturalized. The mulberry is usually monœcious; the staminate flowers are in loose catkins, the pistillate flowers in short dense spikes; the latter flowers contain a two-celled ovary, with two thread-like styles; one of the cells disappearing after fructification, while the four-lobed calyx becomes fleshy.

Description.—Through the coalescence of the fleshy calyces, the pistillate spikes of the mulberry ripen into what appears to be a compound berry or drupe, having some resemblance to the blackberry. The mulberry is of an ovate form, about 1 inch long, fleshy and juicy, purplish black, each fruit crowned with the filiform styles. The fruit proper is a lenticular akene inclosed in the fleshy calyx. Mulberries have scarcely any odor, but they possess a very agreeable acidulous taste.

The fruit of *Morus rubra*, Lin., which is common in rich woods in the United States, is oblong, one to near two inches long, and otherwise resembles the preceding.

Constituents.—From comparative experiments made in the laboratory of Fresenius (1857), it appears that mulberries contain more sugar than gooseberries, currants, strawberries, raspberries, blackberries, and huckleberries, while in the free acid they are about intermediate between wild and cultivated raspberries. The analytical results, as obtained by Van Hees, were as follows, calculated for 100 parts of the fruit: sugar 9.192, free acid (estimated as malic acid) 1.860, albuminous compounds 0.394, pectin, gum, and other organic compounds 2.031, ashes 0.566, and water 84.707 parts, the remaining 1.250 parts consisting of the akenes and other tissues, with the insoluble organic compounds and ash.

C. R. A. Wright and G. Patterson (1878) examined the juice expressed from mulberries not quite ripe, and obtained from the liter 26.83 grams of citric acid, 7.82 malic acid, 2.74 glucose, 23.37 other organic constituents, and 9.40 ash; a total of 70.16 grams of solids. This juice had slightly fermented, and contained a trace of volatile probably acetic acid.

Off. Prep.—Syrupus mori, *Br.*

Medical Uses.—Mulberries are refreshing to the taste like all subacid fruits, and slightly laxative. Their fresh juice, or a syrup prepared with it, is frequently employed in Europe for the same purposes to which in this country the juice and jelly of currants are applied, viz., in inflammations with *fever*, and especially in *sore throat.* The bark of the root of morus nigra has been found an efficient substitute for pomegranate root in the treatment of *tænia.*

MORPHIA, *U. S.*—MORPHIA.

Morphinum, P. G.; *Morphium, Morphina.*—*Morphine*, Fr.; *Morphin*, G.
Formula $C_{17}H_{19}NO_3.H_2O$. Molecular weight 303.

Preparation.—Take of Opium sliced twelve troyounces; Water of Ammonia six fluidounces; Animal Charcoal in fine powder, Alcohol, Distilled Water, each a sufficient quantity. Macerate the opium with four pints of distilled water for twenty-four hours, and, having worked it with the hands, again macerate for twenty-four hours, and strain. In like manner, macerate the residue twice successively, with the same quantity of distilled water, and strain. Mix the infusions, evaporate to six pints, and filter; then add five pints of alcohol, and afterwards three fluidounces of the water of ammonia, previously mixed with half a pint of alcohol. After twenty-four hours pour in the remainder of the water of ammonia, mixed, as before, with half a pint of alcohol, and set the liquid aside for twenty-four hours that crystals may form. To purify these, boil them with two pints of alcohol until they are dissolved, filter the solution, while hot, through animal charcoal, and set it aside to crystallize. *U. S.*

This process is essentially that of Dr. E. Staples (1829). On maceration with water, the morphia, minute traces excepted, is readily dissolved together with other constituents. To decompose the morphia salt, ammonia is added; by this process, the morphia is rapidly deposited, together with narcotina, and some of the other alkaloids, and mixed with considerable coloring matter, from which it may be freed by repeatedly recrystallizing from dilute hydrochloric acid and expression, by which the coloring matter and narcotina are removed, while at the same time not an inconsiderable amount of hydrochlorate of morphia enters the mother liquors, from which it may be subsequently recovered. If, however, the concentrated infusion of opium is mixed with not more than an equal bulk of alcohol, and a sufficient amount of ammonia water is added, the morphia will be more slowly precipitated in a crystalline condition, while the great bulk of the coloring matter remains in solution. The slower the separation of the alkaloid, the larger and purer will be its crystals; hence the advantage of adding the ammonia in separate portions. Since morphia is soluble in ammonia, only sufficient of the latter should be added to unite with the acids, and, if in slight excess, it should be allowed to evaporate by exposure. The mother liquid from this evaporation is rejected by the Pharmacopœia, but it contains a small amount of morphia, which, when working on a larger scale, it is important to recover. The alcohol may be distilled off, and, if not otherwise purified, may be reserved for a similar purpose. If the process has been well conducted, the crude morphia has a light-brownish color, which is removed by dissolving in hot alcohol and treating with animal charcoal. The mother liquor from this crystallization retains a portion of the morphia, together with the narcotina, first precipitated. On distilling off the alcohol, the alkaloids are obtained, and may be preserved until sufficiently accumulated for further purification. Narcotina may be removed from morphia by treatment with ether, in which the former is readily soluble, the latter entirely insoluble.

Many other processes have been proposed. As a rule, the treatment of opium with acidulated water or alcohol offers no advantages, since more narcotina and other organic compounds are thereby dissolved. Wittstock proposed to separate the narcotina from the infusion of opium by chloride of sodium, in which the narcotina is insoluble, but some morphia is likewise liable to be deposited. The first precipitation with ammonia is sometimes effected at a boiling temperature; after cooling, the morphia will be granular, and may be more advantageously washed with cold water and expressed. Precipitation with carbonate of sodium does not appear to insure a larger yield. Pelletier observed that when acetic acid is added to crude powdered morphia until the liquid begins to retain an acid reaction, all the morphia will be dissolved, while the narcotina remains behind; and this behavior may be used for separating the two alkaloids; or the impure morphia may be completely dissolved in dilute acetic acid, the solution evaporated to dryness, and the residue treated with water, which leaves narcotina. Gregory has proposed a process which has been adopted by the British Pharmacopœia for preparing hydrochlorate of morphia from opium, and which has the advantage of dispensing with alcohol in the purification of the alkaloid. To obtain this in a pure state, the following directions are given: Take of Opium sliced one pound; Chloride of Calcium three-quarters of an ounce; Purified Animal Charcoal one-quarter of an ounce; Solution of Ammonia, Distilled Water, each a sufficiency. Macerate the opium for twenty-four hours with two pints of the water, and decant. Macerate the residue for twelve hours with two pints of the water, decant, and repeat the process with the same quantity of the water, subjecting the insoluble residue to strong pressure. Unite the liquors, evaporate in a water-bath to the bulk of one pint, and strain through calico. Pour in now the chloride of calcium, previously dissolved in four fluidounces of distilled water, and evaporate until the solution is so far concentrated that upon cooling it becomes solid. Envelop the mass in a double fold of strong calico, and subject it to powerful pressure, preserving the dark fluid which exudes. Triturate the squeezed cake with about half a pint of boiling distilled water, and, the whole being thrown upon a paper filter, wash the residue well with boiling distilled water. The filtered fluids having been evaporated as before, cooled, and solidified, again subject the mass to pressure; and, if it be still much colored, repeat this process a third time, the expressed liquids being always preserved. Dissolve the pressed cake in six fluidounces of boiling distilled water; add the animal charcoal, and digest for twenty minutes; wash the filter and charcoal with boiling distilled water, and to the solution thus obtained add the solution of ammonia in slight excess. Let the pure crystalline morphia which separates as the liquid cools, be collected on a paper filter, and washed with cold distilled water until the washings cease to give a precipitate with solution of nitrate of silver acidulated by nitric acid.

From the dark liquids expressed in the above process an additional product may be obtained by diluting them with distilled water, precipitating with solution of potash added in considerable excess, filtering, and supersaturating the filtrate with hydrochloric acid. This acid liquid, digested with a little animal charcoal and again filtered, gives, upon the addition of ammonia, a small quantity of pure morphia. *Br.*

In this process the morphia salts, as naturally contained in the opium, are decomposed by an excess of calcium chloride with the formation of hydrochlorate of morphia, which, crystallizing on cooling from the sufficiently concentrated solution, produces, with the calcium meconate, a solid mass, from which the mother liquor is removed by strong pressure. The pressed cake, on being treated with boiling water, yields up the morphia (and codeia) hydrochlorate, while the calcium meconate remains upon the filter. The evaporation, expression, and resolution are repeated until most of the coloring matter has entered the mother liquors, and nearly the whole of the calcium meconate remains upon the filter. The removal of the last traces of color is then effected by animal charcoal, and the morphia precipitated in a granular condition by adding a slight excess of ammonia to the boiling solution. The dark-colored mother liquors contain, besides coloring matter and calcium salts, narcotina and morphia, which are precipitated by potassa, an excess of which dissolves the latter readily and completely, but narcotina sparingly and slowly, as observed by Robiquet, Wittstock, and others. The filtration of the strongly alkaline liquid must, therefore, not be long delayed; and when the clear liquid is acidulated with hydrochloric acid it contains morphia hydrochlorate, potassium chloride, and some coloring matter, from the last of which it is freed by animal charcoal; ammonia then precipitates the nearly pure alkaloid. The decoloration of the morphia salt by means of animal charcoal is more readily effected when in aqueous solution, as here directed, than when dissolved in alcohol.

Lime has an action upon morphia and narcotina similar to that of potassa. Couërbe has founded upon this behavior a method for preparing morphia, which was somewhat modified by Mohr (1840), who directs four parts of opium to be exhausted by repeated boiling with water; the strained and expressed decoction is gradually added to boiling milk of lime, made of one part of burned lime and eight parts of water; and after boiling for a few minutes, the mixture is strained, pressed, and the insoluble portion twice boiled with a fresh portion of water. The liquid, containing mainly morphia, lime, and coloring matter, is concentrated to eight parts, filtered, and the filtrate, while boiling, mixed with sufficient powdered sal ammoniac to convert all the lime into calcium chloride, while ammonia is given off, and the morphia, on cooling, separated as a granular mass; this is washed with cold water, dissolved in hydrochloric acid, purified with animal charcoal, and crystallized as hydrochlorate of morphia, or the alkaloid precipitated by ammonia. The morphia precipitated from the lime solution is darker in color than the first morphia precipitate obtained by Staples' process, but much lighter than the corresponding precipitate by Gregory's process.

Properties.—Morphia crystallizes in short, transparent, and colorless or white prisms, which require for solution about 1000 parts of cold and about 500 parts of boiling water, 30 parts of boiling and 50 parts of cold alcohol, 60 parts (175 parts, Pettenkofer) of chloroform and 220 parts of glycerin. It is soluble in fusel oil, also in fixed alkalies and alkaline earths, less so in ammonia and its salts, but insoluble in benzol, fixed oils, and ether; the latter liquid dissolves some morphia in the amorphous state, which crystallizes after awhile. It is inodorous, and at first tasteless, developing, however, a bitter taste. Its solutions have an alkaline reaction upon test-paper, and with acids it yields salts, most of which are crystallizable. Heated to 120° C. (248° F.) it loses 5.95 per cent. of water of crystallization, and fuses to an oily liquid, which crystallizes on cooling; at a higher heat it is decomposed, and burns without leaving any residue.

Tests.—Commercial concentrated sulphuric acid dissolves morphia with a yellowish, afterwards gray color. Pure morphia, heated with pure sulphuric acid to 100° C. (212° F.) for half an hour, is colored pink-red (Prescott, 1877). Concentrated nitric acid imparts a blood-red color, changing to orange and yellow. Dissolved in sulphuric acid, and the solution heated to near 150° C. (302° F.) the addition of little nitric acid colors violet-blue, changing quickly to blood-red, and afterwards to deep orange (Husemann, 1863). *Froehde's reagent* (1866) (0.001 sodium molybdate in 1 c. c. H_2SO_4) acquires a beautiful violet color, changing to blue, olive-green, yellow, and, in twenty-four hours, to purplish-blue. In the reaction of this reagent upon many alkaloids and other organic substances, a light- or dark-blue, or more or less green, color is produced; the changes in color must therefore be noticed, and a larger amount of the molybdate in the test carefully avoided. (See paper by Buckingham in *Amer. Journ. Pharm.*, 1873, p. 150.) Chlorine water added to morphia causes a yellow or orange color, which is deepened by alkalies; chlorinated alkalies or lime at once produce the orange color. Morphia decomposes iodic (Serullas) and periodic (Boedeker) acids, liberating iodine; in dilute solutions the addition of sulphuric acid is advisable; ammonia deepens the yellow color of the solution. Ferric chloride colors morphia and its salts deep blue, the color being destroyed by free acids and alcohol, but not by alkalies (Robinet). Pellagri (1877) recommended a test which depends upon the production of apomorphia (see p. 191), and is applied as follows: the suspected substance is dissolved in concentrated muriatic acid, a little sulphuric acid is added, and the solution evaporated at 100° C.; a purple color will be produced. To the residue is added a little muriatic acid, then bicarbonate of sodium, and, finally, a strong solution of iodine in hydriodic acid, when a green compound is produced, dissolving in ether with a purple color.

The *salts of morphia* are precipitated from their solutions by the alkalies and alkaline earths, the precipitates being soluble in an excess of the precipitant. Similar precipitates are produced by the alkaline carbonates and cyanides, but the alkaline bicarbonates fail to precipitate acid solutions in the cold. Tannin causes a white precipitate soluble in acetic acid and in alcohol. Auric or platinic, but not mercuric, chloride occasions a yellow precipitate. The acidulated solutions of morphia are precipitated by phosphomolybdic acid, potassio-mercuric iodide, potassio-cadmium iodide, and other general reagents for alkaloids. 1 c. c. of Mayer's test solution precipitates 0.020 gram morphia. When a salt of morphia is heated with an excess of sulphuric or hydrochloric acid to near 150° C. (302° F.), the alkaloid parts with H_2O, and is converted into apomorphia, $C_{17}H_{17}NO_2$. (See page 190.)

Pharmaceutical Uses.—The alkaloid is used in preparing the salts of morphia.

Physiological Action. *On Animals.*—As the effects of the several salts of morphia are nearly identical, it will be convenient to study them in connection with the alkaloid itself. The first remark is that birds, in many instances, tolerate the action of morphia, when taken into the stomach, to an almost incredible degree; thus it has been found that of two pigeons, one might survive a dose of twelve grains, while it would prove fatal to the other bird. Even hypodermically, three grains were required to destroy life. In these animals morphia appears to act upon the spinal marrow rather than upon the brain, causing unsteady movements, partial paralysis, and general convulsions. Analogous results have followed experiments upon rabbits, dogs, and horses. Thus six grains of acetate of morphia administered to a dog caused paralysis of the hind legs, salivation, somnolency, and *dilated* pupils; but the animal recovered. A like result followed the administration of twelve grains of morphia to a horse. It should, however, be stated that in exceptional cases morphia has appeared to produce true, and even fatal, narcotism in birds. So, too, in certain experiments upon dogs a true narcotic operation has been observed; on awaking, the animals looked terrified and haggard, dragged their hind legs, failed to recognize their masters, and slunk into a dark corner, where they remained for many hours, and until the intoxication had entirely passed away. The rationale of its action upon animals may, according to Witkowski, be expressed in the following propositions: 1. Morphia paralyzes the cerebral centres of sensation and motion in the brain. 2. The paralysis of these centres is preceded by their excitement. 3. This paralysis precedes that of the respiratory centres. 4. The centres of the inhibitory vagus fibres, the vascular nerves, and those which contract the pupil, are neither depressed nor stimulated by morphia. 5. Spinal reflex excitability is heightened by morphia. 6. The peripheral nerves are in no manner affected by morphia.

On Man.—The general effects of morphia on the system are almost identical with those of opium, but there are some points of difference which call for notice, and some peculiarities depending upon the manner in which morphia is administered. It does not appear to stimulate the nervous system or the circulation as much as opium, nor display so decided a narcotic influence. It has been remarked that although two or even three grains of opium certainly contain less than a grain of morphia, yet their action is more intense, rapidly occasioning a degree of narcotism bordering upon coma, but soon subsiding without leaving decided secondary effects behind; while morphia does not readily produce narcotism, but its after-effects are of longer duration. Opium also increases the temperature as well as the sense of heat, but morphia while agreeing in the latter effect lowers the temperature. So, too, opium primarily increases the frequency of the pulse, but morphia diminishes it. Opium is less apt to excite nausea and vomiting than morphia. Of this operation it has been remarked that women are much more liable to it than men, and especially to vomiting. When morphia is used hypodermically, such effects usually take place immediately, but when given by the stomach they may not appear for several days. A corresponding contrast is presented by its action on the bowels; by the hypodermic method morphia continues to constipate, but by the mouth it tends to occasion diarrhœa after a few days. Under like circumstances, opium does not cause looseness of the bowels, but ceases to confine them. Morphia is very apt to occasion ardor urinæ, with vesical irritation, and diminished secretion of urine. The last symptom may be accounted for, in part, by the profuse sweating that often follows the administration of morphia in full doses. It is said to be more marked in females than in males. Although itching of the skin sometimes attends the action of opium, it is usually insignificant compared with that which morphia frequently causes. It generally begins in the eyes and nose, and often extends to the whole surface of the skin, causing great restlessness and distress. Along with this symptom, or independently of it, various fugitive eruptions appear, of a papular or erythematous description, and especially urticaria. They probably depend upon the same immediate cause that provokes diaphoresis; and they have been oftener noticed after the hypodermic use of morphia than otherwise. Like all narcotics, so with morphia; if it is left off abruptly wakefulness and restlessness, with nervous depression, are very apt to ensue. The fatal dose of morphia cannot be determined; it may not exceed a single grain; and, on the other hand, a case is recorded in which seven grains of morphia were taken in the form of Magendie's solution, and yet, by dint of powerful excitation, chiefly electrical, the patient recovered. (Schweig.)

The influence of morphia used habitually by hypodermic injection is most pernicious. Even in dogs, after a time emaciation sets in and ultimately reaches an extreme degree; the animal is habitually torpid, the skin of the feet grows morbidly sensitive, and the temperature is very low. After death the brain and spinal marrow are anæmic, and the lungs and liver engorged. In man the effects are similar, but those of the intellectual sphere are predominant. They include nervousness, tremor, hyperæsthesia, spasms, neuralgia, insomnia, anxiety, hypochondria alternating with excitement, hallucinations, dryness of the tongue, constipation and scanty urine, with vesical irritation, and sometimes albuminous urine. If the drug is abruptly withdrawn the patients suffer a collapse, with indescribable distress from nervousness and loss of self-control, profuse sweats, and a dusky discoloration of the face.

Many cases occur in which idiosyncrasies modify the usual effects of morphia. In some it causes violent mental excitement, hallucinations, and a total inability to sleep. In others it occasions nervous depression, syncope, pallor of the skin, feebleness of the pulse, dyspnœa, insensibility, urgent vomiting, etc. In others again spasmodic movements, or a fully formed tetanoid paroxysm. No doubt some of the most alarming examples of this nature have followed the hypodermic injection of morphia, either because of the swift absorption of the narcotic, or from its having been thrown into a vein. Hence the wisdom of the rule to introduce morphia hypodermically with great deliberation; and the advice that has been given to associate with each injection one-ninety-sixth of a grain of atropia to counteract the depressing and nauseating effects of the morphia.

Medical Uses.—Although morphia may, in general terms, be used for the same purposes as opium (see Opium), especially as an internal medicine, it is true, nevertheless, that the introduction of the hypodermic method of employing it has shown its fitness for certain special conditions. This method is superior to any other when the prompt action of the medicine is necessary to save life or lessen pain; when the patient is unable or unwilling to swallow; and when a local rather than a general influence is intended. In *sunstroke* attended with convulsions, jactitation, delirium, and general excitement, the hypodermic injection of a salt of morphia, in the dose of a quarter of a grain, affords prompt relief. In *epileptiform convulsions* due to mental excitement, in pregnancy and the *puerperal state*, in *hysteria* and aggravated *chorea*, in various *local spasms*, as of the face, glottis, diaphragm, etc., this remedy should always be borne in mind. Morphia hypodermically employed is perhaps the best remedy in *tetanus*, even of the traumatic form, and a like statement is true of the analogous condition caused by *strychnia* poisoning. It is the proper antidote in poisoning by belladonna or atropia. Of all the remedies for *spasmodic asthma* this one procures incomparably the most speedy relief. The pain of *neuralgia*, especially in its severer forms, such as affect the fifth nerve, the sciatic, and the gastric nerves, is promptly palliated by it. In neuralgia of the superficial nerves rapid vesication of the skin over the painful points, and the application to the cutis of a strong solution or ointment containing a morphia salt, may also be employed; but its effect is less prompt and sure than the hypodermic plan. Of all palliatives employed in that most terrible of pains, *angina pectoris*, none affords more prompt and sure relief, not only subduing the neuralgic anguish, but calming the tumultuous and disordered movements of the heart. It has the advantage over other methods of being almost free from danger. One of the best occasional remedies for *nervous headache* which females are apt to experience during the menstrual periods, is a cup of strong coffee with a fifth of a grain of a morphia salt; but it is a remedy which is not to be recommended for general or frequent use. The use of morphia as an antidote to poisoning by *belladonna*, *atropia*, and *Calabar bean*, is considered under those several titles.

Like all new methods, the hypodermic use of morphia has been greatly perverted; the prompt alleviation of pain and the pleasing intoxication which follows form too strong a temptation to its use for all persons to resist successfully. Like alcohol, its intoxication leaves behind it a sense of debility and depression which nothing but a fresh resort to the medicine relieves. If continuously employed, it creates an artificial necessity for resorting to its powerful and genial support, and the longer it is used the larger is the dose required. A peculiar allurement of the habit as compared with that of taking opiates by the mouth is that in many cases it does not so readily derange the stomach, impair the appetite, or produce constipation. These effects should be borne in mind, but it is equally important to remember that in cases of hopeless disease the duty of the physician is, above everything else, to relieve his patient's suffering.

The average *dose* of morphia or of its salts is about one-fifth of a grain; but morphia, uncombined, is seldom prescribed. For hypodermic uses an officinal solution of morphia has been provided by the British Pharmacopœia. See Injectio morphiæ hypodermica.

MORPHIÆ ACETAS, *U. S.*, *Br.*—ACETATE OF MORPHIA.

Morphinum aceticum, P. G.; *Acetas morphinæ, Acetas morphicus.—Acétate de morphine*, Fr.; *Essigsaures Morphin*, G.

Formula $C_{17}H_{19}NO_3.C_2H_4O_2.H_2O$. Molecular weight 363.

Preparation.—Take of Morphia in fine powder a troyounce; Distilled Water half a pint; Acetic Acid a sufficient quantity. Mix the morphia with the distilled water; then carefully drop acetic acid into the mixture, stirring it constantly, until the morphia is neutralized and dissolved. Evaporate the solution, by means of a water-bath, to the consistence of syrup, and set it aside until it concretes. Lastly, dry the salt with a gentle heat, and rub in into powder. *U. S.*

The British Pharmacopœia, not recognizing morphia as officinal, requires that alkaloid to be prepared from the hydrochlorate; in other respects the manipulation is identical with the foregoing, except that a much smaller quantity of water is very properly directed for effecting the solution of morphia and its neutralization with the acetic acid. A very slight excess of acetic acid is rather of advantage, since the salt begins to decompose during the evaporation by the liberation of a little acid; it is, therefore, advisable to facilitate evaporation at a rather low temperature by means of a current of air. The salt may be crystallized with some difficulty in the form of white silky needles; but is very generally obtained in powder as directed above.

Properties.—Acetate of morphia forms a white powder, which has a slight acetous odor and very bitter taste. It is readily and freely soluble in water, less freely soluble in alcohol, and soluble in 60 parts of chloroform; it is insoluble in ether. Cold strong sulphuric acid dissolves it without color only when recently made. When kept on hand, it slowly loses acetic acid, and becomes incompletely soluble in water unless a little acetic acid be added; it gradually acquires a yellowish-gray and finally brownish color, and should then be redissolved in acetic acid and evaporated or converted into another salt of morphia. Its aqueous solution undergoes similar changes, the acetic acid being slowly decomposed with the separation of brown flocculent compounds, while the morphia crystallizes out, forming long prisms, if the solution is not disturbed. The salt contains 78.5 per cent. of anhydrous or 83.5 per cent. of crystallized morphia.

The salt responds to the morphia tests described above, and leaves no residue when ignited. If its solution is precipitated by tannin, the addition of dilute hydrochloric acid redissolves the precipitate; a remaining turbidity would indicate the presence of narcotina.

Off. Prep.—Liquor morphiæ acetatis, *Br.*

Medical Uses.—The action and uses of the acetate are the same that have been described in the article on Morphia. The *dose* of the acetate is about one-fifth of a grain.

MORPHIÆ MURIAS, *U. S.*—MURIATE OF MORPHIA.

Morphiæ hydrochloras, Br.; *Morphinum hydrochloricum*, P. G.; *Murias (Hydrochloras) morphicus.—Hydrochlorate of morphia*, E.; *Chlorhydrate de morphine*, Fr.; *Salzsaures Morphin*, G.

Formula $C_{17}H_{19}NO_3.HCl.3H_2O$. Molecular weight 375.5.

Preparation.—Take of Morphia in fine powder a troyounce; Distilled Water four fluidounces; Muriatic Acid a sufficient quantity. Mix the morphia with the distilled water, then carefully drop muriatic acid into the mixture, stirring it constantly, until the morphia is neutralized and dissolved. Evaporate the solution, by means of a water-bath, so that on cooling it may crystallize. Lastly, drain the crystals and dry them on bibulous paper. *U. S.*

The British Pharmacopœia has a process for preparing this salt from opium, which was given on page 914, as far as the precipitation of pure morphia. The remaining steps are essentially identical with the above, but are more practical in saving evaporation by employing a smaller quantity of boiling distilled water, in which the morphia is diffused and neutralized by the acid, the hydrochlorate crystallizing out on cooling. If pure morphia has been used and an excess of hydrochloric acid avoided, the salt may be wholly obtained in crystals by judicious evaporation of the mother-liquor.

Properties.—Hydrochlorate of morphia crystallizes in white silky needles, or transparent prisms having a bitter taste. It is soluble in 20 parts of cold, and in less than its own weight of boiling water, in 60 parts of cold, and in 10 parts of boiling 80 per cent. alcohol, in 19 parts of glycerin, and in 800 parts of olive oil; it is insoluble in ether. Heated to 130° C. (266° F.), it loses 14.38 per cent. of water of crystallization. It yields 75.9 per cent. of anhydrous, and 80.7 per cent. of crystallized morphia.

The salt answers to all the morphia tests described before; its aqueous solution yields, with nitrate of silver, a white precipitate, which is insoluble in nitric acid, but dissolves in ammonia.

Off. Prep.—Liquor morphiæ hydrochlor., Supposit. morphiæ, Suppos. morphiæ cum sapone, Trochisci morphiæ, Troch. morphiæ et ipecacuanhæ, *Br.*

Medical Uses.—Its operation is identical with that of the acetate, and its *dose* is the same, or about one-fifth of a grain.

MORPHIÆ SULPHAS, *U. S.*—SULPHATE OF MORPHIA.

Morphinum sulfuricum, P. G.; *Sulfas morphicus.*—*Sulfate de morphine*, Fr.; *Schwefelsaures Morphin*, G.

Formula $(C_{17}H_{19}NO_3)_2H_2SO_4.5H_2O$. Molecular weight 758.

Preparation.—Take of Morphia in fine powder a troyounce; Distilled Water half a pint; Diluted Sulphuric Acid a sufficient quantity. Mix the morphia with the distilled water; then carefully drop diluted sulphuric acid into the mixture, stirring it constantly, until the morphia is neutralized and dissolved. Evaporate the solution, by means of a water-bath, so that on cooling it may crystallize. Lastly, drain the crystals, and dry them on bibulous paper. *U. S.*

This process involves the neutralization of pure morphia with dilute sulphuric acid and the subsequent crystallization of the salt. If about two, instead of eight, fluidounces of water are used at the boiling temperature, the solution will crystallize on cooling. The mother-liquor, on further concentration, will yield more of the salt.

Properties.—It crystallizes in white fascicles of transparent needles, which, on being heated to 130° C. (266° F.), lose 11.8 per cent. of water of crystallization. It is soluble in two parts of water, less freely so in alcohol, and in five parts of glycerin (Adolphus, 1867). It is insoluble in ether. The salt yields 75.2 per cent. of anhydrous, and 79.94 per cent. of crystallized morphia, and when ignited leaves no residue. Its aqueous solution yields a white precipitate with chloride of barium, insoluble in nitric acid. To the reagents for morphia it has the behavior described on page 915. Dott (1877) noticed an article sold in England which was adulterated with 34.63 per cent. of anhydrous sodium sulphate.

Off. Prep.—Liquor morphiæ sulphat., Suppos. morphiæ, Trochisci morphiæ et ipecacuanhæ, *U. S.*

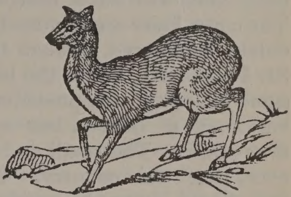
Medical Uses.—Sulphate of morphia is more generally used than any of the other salts of this alkaloid. Its *dose* is about one-fifth of a grain.

MOSCHUS, *U. S.*, *Br.*—Musk.

Musc, Fr.; *Moschus*, G.

The dried secretion from the preputial follicles of Moschus moschiferus, *Lin.* *Class* Mammalia. *Ord.* Ruminantia.

Fig. 110.



Musk-deer.

Origin.—The musk-deer resembles the deer (*Cervus*), but differs from it in the want of horns and in the canines, which are lóng and project considerably downwards from the lips of the male. It inhabits chiefly the mountainous regions and elevated tablelands of Central Asia, and is met with from Anam, in Further India, northwestward to Thibet and northward in China and Tartary to Mantchooria and Southern Siberia. It lives in pine forests in the Himalayas, frequently at an altitude of 10,000 to 14,000 feet. The musk-sac is found in the male only, and is located on the abdomen, immediately before the preputial orifice and to the rear of the umbilicus. The animal has nocturnal habits, and is taken by snares and pitfalls, or sometimes by shooting; the sac is cut off as soon as possible, and rapidly dried by pressing it against heated stones.

Description.—The musk-bag (called sac, pod, or pouch) is oval in shape, about 2 inches long and 1½ inch wide, with a thickness of about half an inch. The upper surface is smooth and flat, the lower surface convex and hairy. The hairs are grayish and brown, rather stiff and appressed, and arranged in a circle towards the aperture near the centre of the bag, and in the form of a pencil towards the preputial orifice, which is about one-fourth inch in the rear of the former. From this orifice underneath the hairy skin between the strata of the muscular coat and towards the posterior end of the sac is a canal containing the front portion of the thin penis. Following the muscular coat is the musk-pouch proper, with an external fibrous coat, having on the inner surface numerous depressions resembling meshes and surrounded by folds, and covered by two coats, the one soft and pearly, and the other very delicate, silvery-white on the outside, and yellowish or brownish on the inside. The musk is supposed to be separated by a number of glands, of which two or more are situated in each depression. In the young animal, the secretion is slight and of a milky appearance; but after

Fig. 111.

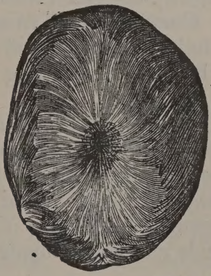


Fig. 112.

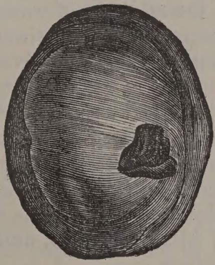


Chinese Musk-sac.

Lower surface. Upper surface.

it has passed its third year, the musk is of better quality; in the fresh state it is of an unctuous consistence.

From a record kept by Messrs. Cramer and Small (*Amer. Journ. Pharm.*, 1872, p. 565), the average weight of Chinese musk-bags was found to be 394 grains, and of the musk in each 157 grains.

Musk is of a crummy appearance, near the musk orifice mixed with grayish hairs, of a reddish-brown color, or darker brown and irregularly granular, of a strong diffusible and persistent odor and bitterish taste. When entirely exsiccated, it is almost inodorous, but the odor reappears on moistening and is increased by the addition of a little alkali. Musk should be kept in not too warm and dry a place where the air has some access to it.

Varieties.—Several varieties are known in commerce, the best being the *Chinese*, *Thibet*, or *Tonquin* musk. It is usually imported in small boxes, internally lined with sheet lead and containing about 25 sacs, each wrapped in paper. The outer hairs are trimmed short, and are of a yellowish or grayish color. Musk enters commerce through the Chinese ports. *Siberian musk* comes by way of St. Petersburg, hence the name *Russian musk;* it often resembles and has the same quality as the preceding; when in flatter ovate sacs with thinner and paler hairs, and of fainter, less aromatic, and more urinous odor, it is called *Cabardine musk.* The small and inferior *Bucharian* and *Assam musk* sacs rarely, if ever, reach this country. Chinese musk only should be employed in medicine, and should always be purchased in sacs.

Substitutions and Adulterations.—The substitution of artificial musk-bags, made from a piece of the hide stitched to a membrane, is readily recognized by the absence of the circular arrangement of the hairs and of the central aperture. Genuine sacs are sometimes slit open, the musk partly removed, and other substances introduced in place thereof. They may usually be detected by being stitched together on the edge of the hide and inside membrane. There is no means of detecting the fraudulent introduction through the orifice of pieces of lead, etc., until after the bags have been opened.

Tests.—Cold water dissolves about one-half the weight of the musk; the solution is deep brown, faintly acid, and scarcely disturbed by solution of corrosive sublimate. Weak alcohol yields a similar solution. Absolute alcohol dissolves about 10 per cent., yielding a slightly colored tincture, which scarcely becomes turbid on the addition of water. Carefully freed from fragments of skin and hairs and heated upon platinum foil, musk gives off an odor which is slightly urinous, but very distinct from the odor of burning blood, and leaves about 6 to 8 per cent. of a gray, not red, ash.

Constituents.—Musk, treated with potassa, gives off ammonia; it contains cholesterin, various fatty and waxy substances, gelatinous and albuminous compounds, and salts. The odorous principle volatilizes partly with the vapors of water, but is not a volatile oil; it is most probably formed in the presence of moisture, by the slow and continuous decomposition of one of the constituents.

Camphor, oil of bitter almonds, and acids generally impair the odor of musk, or destroy it altogether.

Pharmaceutical Uses.—TINCTURA MOSCHI, *P. G.;* Tincture of musk, *E.;* Teinture de musc, *Fr.;* Moschustinktur, *G.* Two parts of musk are triturated with 50 parts of water; 50 parts of alcohol, specific gravity 0.892, are added, and the whole macerated for eight days. *P. G.* The tincture has a reddish-brown color, which is darker than that of the tincture made by macerating 10 parts of musk in 100 parts of 80 per cent. alcohol, as directed by the French Codex.

Tincture of musk is employed in perfumery for rendering delicate odors more permanent.

Physiological Action.—Injected into the veins of animals musk has produced a degree of narcotism with muscular spasms, followed by bloody stools, exhaustion, and death; after which cadaveric rigidity and mucous injection were found. In man it produces an effect comparable to that of alcohol, since, after stimulating the brain and heart and raising the temperature, it occasions, according to some, drowsiness and thoracic oppression; but, according to others, leaves no reactionary effects behind. Its odor continues for several days to impregnate the breath and all the secretions.

Medical Uses.—The scarcity, high price, and falsification of musk have caused its use to be comparatively restricted, and explain the varying and often contradictory estimates of its value as a medicine. Yet, on the whole, the conditions it is adapted to remedy are pretty well defined. They include all those nervous phenomena which are represented by the term *ataxia*, and among them subsultus tendinum, mild muttering delirium, floccitation, muscæ volitantes, and hiccup, with a small, frequent, tremulous or irregular pulse, without coma and without collapse. Under these circumstances musk tends to produce refreshing sleep, while it calms muscular spasm and favors perspiration, and the pulse grows fuller, more regular, and less frequent. These are the phenomena which may occur in all febrile diseases originally of a typhoid type or tending to assume it, and notably in *typhus*, *typhoid fever*, the *eruptive fevers*, and certain inflammations also, but particularly *pneumonia*. In proportion as ataxic prevail over adynamic phenomena is musk advantageous. Ataxic phenomena are often met with in the advanced stages of *cholera infantum*, besides others that indicate serous effusion upon the brain; and they are sometimes dissipated by the administration of musk.

Its fitness to combat the special phenomena above indicated is illustrated by its efficacy in purely nervous and non-febrile affections. There can be no doubt of its having repeatedly effected a cure in cases of *hiccup*, *pharyngeal spasm*, *laryngismus stridulus*, *spasmodic croup* (spasmodic laryngitis), *spasmodic cough*, *whooping cough*, *vomiting*, and *colic*. Even *chorea*, *hysterical convulsions*, and *tetanus* have occasionally been cured by its means. Its power as a nervine is also shown by its relieving *wakefulness* resulting from combined mental and bodily fatigue; such cases, in fact, as are benefited by valerian, camphor, asafœtida, and ammonia.

Musk is usually administered in pill or emulsion, and in *doses* of ten grains or upwards, every two or three hours. It may also be employed in suppositories. To children it may be given in doses of one or more grains in the above-mentioned forms, or in a small enema.

MOXA.—Moxa.

Moxa, Fr.; *Brenncylinder*, G.

Moxas are vegetable substances, either cut or formed into short cylinders, and which when ignited will burn without fusing. In China and Japan moxas are made of the felt-like down covering the leaves of Artemisia chinensis, *Lin.*, and perhaps of other plants. In other countries paper, cotton, or hemp impregnated with a weak solution of nitrate of potassium have been employed for the purpose; or the pith of some plants containing sufficient nitrates to sustain an even combustion, like that of the sunflower (see p. 693). Occasionally mixtures have been made of potassium nitrate with substances like lycopodium, beaten together with some adhesive material, and rolled into cylinders of convenient size. Instead of nitrate, chlorate or chromate of potassium has been employed.

Medical Action and Uses.—The moxa is said to have been employed as a form of cautery from time immemorial by oriental nations, particularly the Chinese and Japanese, from whom it was introduced into Europe by the Portuguese; but it was also used by the Egyptians, the Persians, and the Laplanders. The moxa cylinder should be about an inch long and from a quarter to half an inch in diameter. One end of it is applied to the skin and held in its place by a pair of forceps or a *porte-moxa*, while the opposite end is lighted, and the surrounding skin protected by a damp rag, a piece of sticking plaster, or of paper saturated with a solution of alum and dried, and having an aperture in its centre. Combustion is maintained by the breath, or a pair of bellows, until the whole cylinder is consumed. To prevent deep cauterization liquor ammoniæ is applied immediately after the burning. Sometimes the cylinder is moved about within a small area, without permitting any one spot to be deeply involved; or it may be held very near, but without touching the skin; or, finally, it may be removed when the combustion of the moxa has reached to within a line or two of the skin. It should not usually be applied where the skin is the only covering of bone, tendon, ligament, or cartilage; nor to the mammæ, genital organs, or abdomen. The first sensation of heat is apt to be considered agreeable rather than painful, but it increases and grows tolerably severe. Yet we are assured that it causes less pain than either blisters or caustic issues.

In regard to the modus operandi of the moxa, those who have most employed it consider that its action differs from that of hot iron. Some have suggested that a very volatile (anæsthetic) principle is given off by the burning fibres, and in point of fact an empyreumatic oil must in this way be formed upon or near the skin; others consider that the operation is most efficient when there is really no burning of the integument or any serous or purulent discharge.

The remedial uses of moxa are those of counter-irritant agents in general. It seems to have been most efficient in affections of the superficial joints, as the *knee* and the *wrist;* in *white swelling* and *coxalgia;* in diseases of the *vertebræ* and their ligaments, and in *lumbar abscess;* in *neuralgia* and especially in *sciatica;* in *lumbago*, *rheumatic gout*, and *paralysis;* and finally in *chronic bronchitis.*

MUCILAGINES.—MUCILAGES.

Mucilages, Fr.; *Schleime*, G.

These preparations consist of viscid, more or less tenacious and adhesive liquids, or of opaque semi-liquid jellies; in all cases the solvent vehicle is water. All mucilages as directed by the Pharmacopœias are prone to change, and gradually acquire an acid reaction and offensive odor, at the same time becoming more liquid. If not intended for medicinal use, the change may be retarded or prevented by the addition of alum, creasote, or glycerin.

MUCILAGO ACACIÆ, *U. S.*, *Br.*—MUCILAGE OF GUM ARABIC.

Mucilago gummi arabici, P. G.—*Mucilage de gomme arabique*, *Mucilage arabique*, Fr.; *Gummischleim*, G.

Preparation.—Take of Gum Arabic in small fragments four troyounces; Water half a pint. Add the gum arabic to the water, agitate occasionally until it is dissolved, and strain. *U. S.*

Take of Gum Acacia in small pieces four ounces; Distilled Water six fluidounces. Put the gum and water into an earthen jar, and stir them frequently until the gum is dissolved. If necessary, strain the solution through muslin. *Br.*

White and clear pieces of gum arabic should be selected for preparing this mucilage. The impurities which necessitate the subsequent straining are generally accidental admixtures of the gum, and may mostly be removed by rapid washing with cold water before dissolving it. The solution may be effected in a corked bottle by placing it on its side, whereby a more extended surface of the gum is exposed to the solvent action of water, and by agitating it occasionally so as to mix the heavy solution with the lighter liquid. It is a nearly transparent, colorless or scarcely yellowish, viscid liquid, having a faint rather agreeable odor and an insipid taste. To prevent its decomposition, Archer & Co. (1874) employed *tolu water* instead of distilled water, using one fluidrachm of tincture of tolu, rubbed up with carbonate of magnesium, to one pint of water.

Pharmaceutical Uses.—This mucilage serves for the suspension of insoluble substances in mixtures and to impart adhesiveness to pill masses. The British Pharmacopœia directs it to be used as an excipient in the preparation of troches.

Medical Uses.—This mucilage, diluted according to the taste or condition of the patient, sweetened and flavored, forms a customary drink in *fevers*, and in inflammatory affections of the *respiratory* and *digestive* organs. It is probably not directly nutritive, but it very possibly retards tissue waste.

MUCILAGO AMYLI, *Br.*—MUCILAGE OF STARCH.

Mucilage d'amidon, Fr.; *Stärkeschleim*, G.

Preparation.—Take of Starch one hundred and twenty grains; Distilled Water ten fluidounces. Triturate the starch with the water gradually added, then boil for a few minutes, constantly stirring. *Br.*

It should always be made fresh when needed.

Off. Prep.—Enema aloes, Enema magnes. sulphat., Enema opii, Enema terebinthinæ, *Br.*

Medical Uses.—Mucilage of starch is generally intrusted to domestic manufacture; but it may be worth while for physicians to know that one hundred and twenty grains of starch should be mixed with about half a pint of water to procure a liquid of the proper density for an enema such as may be used in *dysentery*. But in that disease if opiates, or any other medicines intended to be retained, are to be added to the mucilage, the quantity of it injected should not exceed three ounces.

MUCILAGO SASSAFRAS MEDULLÆ, *U. S.*—MUCILAGE OF SASSAFRAS PITH.

Mucilage de moelle de sassafras, Fr.; *Sassafrasmark-Schleim*, G.

Preparation.—Take of Sassafras Pith one hundred and twenty grains; Water a pint. Macerate for three hours, and strain. *U. S.*

It is a colorless, thickish, transparent liquid of a bland taste.

Medical Uses.—The mucilage of sassafras pith is a refreshing and useful application to the eye in *acute conjunctivitis*, and may serve as a vehicle for more active agents. It is equally appropriate as a soothing lotion in erythematous and other *inflammations of the skin*. Internally, it may be freely used as a drink in *dysentery* and other bowel complaints, and in *febrile affections* generally.

MUCILAGO TRAGACANTHÆ, *U. S.*, *Br.*—MUCILAGE OF TRAGACANTH.

Mucilage de gomme adragante, *Mucilage adragant*, Fr.; *Traganthschleim*, G.

Preparation.—Take of Tragacanth a troyounce; Boiling Water a pint. Macerate the tragacanth with the water for twenty-four hours, occasionally stirring; then beat the mixture so as to render it of uniform consistency, and strain forcibly through muslin. *U. S.*

Take of Tragacanth in powder sixty grains; Distilled Water ten fluidounces. To the water contained in a pint bottle add the tragacanth, agitate briskly for a few minutes, and again at short intervals, until the tragacanth is perfectly diffused and finally has formed a mucilage. *Br.*

The first formula yields a thick jelly-like mass; the second a more fluid preparation. The former is better adapted as an excipient for troches (U. S.) and many pill masses, but has the disadvantage of drying out and rendering the pills very slowly soluble, a fault which may be corrected by substituting for this purpose, for one-fourth or one-half the quantity of water, an equal bulk of glycerin. Thus prepared it may be readily mixed with aqueous liquids, and serves also a good purpose for suspending insoluble substances.

Medical Uses.—Tragacanth mucilage has scarcely any medicinal qualities peculiar to itself. It is seldom used unless as an excipient in lenitive mixtures, and in troches and lozenges which are intended to dissolve slowly in the mouth. Its tenaciousness has led to its occasional use as a protective for *burns* and *ulcers*.

MUCILAGO ULMI, *U. S.*—MUCILAGE OF SLIPPERY ELM BARK.

Mucilage d'écorce d'orme fauve, Fr.; *Ulmenrinden-Schleim*, G.

Preparation.—Take of Slippery Elm Bark sliced and bruised a troyounce; Boiling Water a pint. Macerate for two hours in a covered vessel, and strain. *U. S.*

Slicing the elm bark will yield a more acceptable preparation, since the mucilage cannot be strained without pressure; and by bruising, the tissues are ruptured and partly forced through the strainer. (See also page 498.)

Medical Uses.—As a demulcent, mucilage of slippery elm is employed in acute affections of the respiratory, digestive, and urinary organs. As a lenitive for external use, it is frequently applied to *erysipelatous* and other acute *cutaneous eruptions*, *abscesses*, *rheumatic joints*, etc. It is very apt to grow sour, and, if allowed to get dry, renders the skin painfully hard and stiff.

MUCUNA, *U. S.*—COWAGE.

Setæ siliquæ hirsutæ.—Cowhage, E.; *Pois velus*, *Pois à gratter*, Fr.; *Kratzbohnen*, *Kuhkrätze*, G.

The hairs of the pods of Mucuna pruriens, *De Candolle*, s. Dolichos (Stizolobium, *Pers.*, Carpopagon, *Roxb.*) pruriens, *Lin.* Woodville, Med. Bot., t. 153; Bentley and Trimen, Med. Plants, 78.

Nat. Ord.—Leguminosæ, Papilionaceæ.

Origin.—This is a long, slender, twining plant, with large trifoliate, nearly smooth leaves, and showy dark-purple and greenish flowers in pendulous axillary racemes, producing flattish, hairy, *S*-shaped legumes, with about four brownish seeds mottled with black. It is cultivated and wild, both in the East and West Indies.

Description.—The hairs covering the legumes are the officinal portion. They are about one-eighth inch long, of a glossy-brown color, straight, quadrangular prismatic, sharply pointed at the apex, somewhat retrorsely serrate on the upper half, and partly empty, partly filled with a brown granular matter. They easily penetrate the skin, and occasion an intolerable itching, which is greatly increased by washing and rubbing.

The fruits of *Stizolobium* (*Mucuna*, D. C., *Dolichos*, Lin.) *urens*, Pers., are shorter, less bent, and covered with shorter and darker hairs, which are used like the preceding. An emulsion of the seeds is used in the West Indies in dysuria; and an infusion of the root of the first species is considered to possess diuretic properties, and in India is employed as a remedy in cholera.

Constituents.—Nothing is known of the composition of cowhage, except that it contains a little tannin and resin (Martius, 1827).

Medical Action and Uses.—Cowhage was originally employed as a *vermifuge*, under the idea that its prickly setæ, which irritate the skin so severely and are so difficult to detach, would wound and injure the worms, and either kill them or promote their expulsion. Observation showed, however, that when the spiculæ are moistened they are quite innocuous, and there is much reason for believing that the supposed vermicide virtues of this substance are imaginary. It is difficult to imagine that an agent which has actually been employed to produce a painful irritation and eruption upon *paralyzed limbs* for the purpose of arousing their dormant functions, should cripple or destroy intestinal worms and leave the intestine itself uninjured. As a vermifuge the setæ are mixed with honey or molasses by dipping the pods in the liquid, and when it has reached the consistence of an electuary it may be given, fasting, in doses of one or more teaspoonfuls for several successive days. Subsequently a purge of calomel and jalap may be prescribed; and this is, doubtless, the most efficient part of the treatment. When formerly used to relieve paralysis, it was applied in a layer upon the affected part, supported by thin paper or similar substance, or else incorporated in simple ointment or lard.

MYRICA.—WAX-MYRTLE.

Bayberry, Candleberry, E.; *Arbre à suif*, Fr.; *Wachsbaum, Wachsgagel*, G.

Myrica cerifera, *Lin.* *Nat. Ord.*—Myricaceæ.

Origin.—The wax-myrtle is shrubby, or sometimes arborescent, usually from four to eight feet high, and grows near Lake Erie, but chiefly along the Atlantic coast of North America. It has alternate, oblong-lanceolate, entire or near the apex sparingly toothed leaves, which are nearly smooth, about two inches long, on both sides covered with resinous dots, and fragrant when bruised. The flowers are diœcious, the staminate ones in nearly cylindrical catkins about three-quarter inch long, the pistillate ones shorter, and producing globular one-seeded nuts, which are of the size of a pea, blackish, and covered with a white waxy incrustation.

The bark and waxy incrustation of the fruit have been employed.

Description.—1. The bark is in quills or curved pieces about one-sixteenth inch thick, externally covered with a whitish, slightly wrinkled, thin, corky layer which separates in small fragments, underneath which the bark is dark reddish-brown and nearly smooth, resembling the inner surface, except that the latter is slightly striate. The fracture is granular, of a pale-reddish color, and scarcely fibrous in the inner layer. The bark yields a light reddish-brown irritating powder, having a peculiar aromatic odor, and an astringent, somewhat bitter and pungently acrid taste.

2. Myrtle-wax, or *bayberry tallow*, is prepared by boiling the fruit with water until the fat collects on the surface. It has a balsamic odor, is harder and more brittle than beeswax, varies in color between green, yellowish, and gray, and breaks with a shallow conchoidal fracture. G. E. Moore (1862) found its specific gravity to range from 1.004 to 1.006, its fusing point from 47° to 49° C. (116.6° to 120.2° F.), and its proximate composition to be about one-fifth *palmitin*, the remainder being *palmitic acid* with a small quantity of *lauric acid*. Four-fifths of the myrtle-wax are soluble in hot alcohol.

Constituents.—The constituents of bayberry bark, as determined by G. M. Hambright (1863), are, besides those more generally met with, a trace of volatile oil, tannin, an acrid resin soluble in alcohol and ether, an astringent resin insoluble in ether, and *myricinic acid*, the latter obtained from the alcoholic extract after having been treated with ether, by exhausting it with hot absolute alcohol. It forms small granules, which produce a thick froth on being agitated with water, and on the addition of ammonia a deep-green color rapidly changing to red and yellow. It has a lastingly acrid taste.

Allied Plants.—Myrica gale, *Lin.;* Sweet gale, Dutch myrtle, *E.;* Piment royal, Galé odorant, *Fr.;* Gagel, Brabanter Myrte, *G.*—This is a smaller shrub than the preceding, growing in swampy places from the mountains of North Carolina northward to Canada, and in the northern part of Europe. The leaves are on short petioles, one and a half inch long, obovate-lanceolate, wedge-shaped at the base, serrate near the apex, subcoriaceous, softly pubescent beneath, and on both sides with yellow resinous dots. The fruit is likewise resinous dotted. The leaves and brown branches have a strong balsamic odor, and an aromatic, astringent, and bitterish taste. Rabenhorst (1836) obtained from 3000 parts of fresh leaves one part of a thickish volatile oil, containing 70 per cent. of stearopten.

A solid fat very similar to myrtle-wax is obtained from the fruit of other species of myrica indigenous to different countries.

Medical Action and Uses.—The bark of the root is acrid and stimulant, and in doses of a drachm causes a sensation of heat in the stomach, followed by vomiting, and sometimes diuresis. When chewed it acts as a sialagogue, and has proved useful in toothache. The powder is an active errhine. The leaves have some celebrity in domestic practice as an antispasmodic, antiscorbutic, and astringent medicine. The other native species are very similar in their properties. The "myrtle-wax" which covers the berries appears to have astringent and slightly narcotic properties, and was used with alleged success in an epidemic of typhoid dysentery, when it was administered in the dose of one or two drachms. (Griffith.)

MYRISTICA, *U. S.*, *Br.*—NUTMEG.

Semen myristicæ, P. G.; *Nux moschata*, *Muscade*, *Noix de muscade*, Fr.; *Muskatnuss*, G.

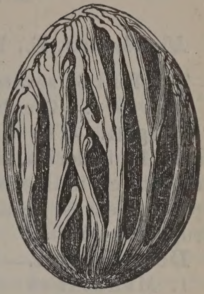
The kernel of the seed of Myristica fragrans, *Houttuyn*, s. M. moschata, *Thunb.*, M. aromatica, *Lam.*, M. officinalis, *Lin. f.* Suppl. Steph. and Church, Med. Bot., plate 104; Bentley and Trimen, Med. Plants, 218.

Nat. Ord.—Myristicaceæ.

Origin.—The nutmeg tree is indigenous to the Molucca Islands, but is at present cultivated in various parts of India, in the Philippines, West Indies, and South America. It attains a height of 30 to 40 feet; has alternate, smooth, entire, and prominently veined leaves, and small, yellowish, diœcious flowers, with the stamens united into a fleshy column, and a superior ovary, ripening into a dehiscent, pear-shaped, tough, one-seeded berry.

Collection.—The fruit is gathered, when split on one side, by means of a long hook fastened to a long stick; the pericarp is removed, and the arillus detached from the nut-like seed (see *Macis*, p. 868), which is carefully dried, on the Banda Islands, first by solar heat for a few days, or in Bencoolen at once on frames over a slow wood fire at a temperature of about 140° F. This requires about two months, during which time the seeds are frequently turned, and when the kernels rattle in the shell they are packed for the Chinese market. The entire seeds do not enter the European and American commerce, but only the kernels, which are removed from the shell by cracking the latter with a wooden mallet, carefully garbled and packed (*unlimed nutmegs*), sometimes mixed with cloves, in casks which have been smoked and whitewashed on the inside. In the Dutch colonies the kernels are dipped in a thick milk of lime (*limed nutmegs*), a custom which originated in the desire to destroy the vitality of the embryo, and thus limit this culture to their own possessions. Small and worm-eaten nutmegs are usually used for obtaining the fixed oil. About 800,000 pounds of nutmegs are annually consumed in the United States.

Fig. 113.



Nutmeg with Mace.

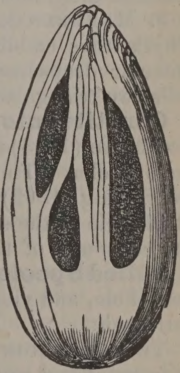
Description.—Nutmeg in the shell is an oval or elliptical seed, about an inch or more in length, with a brown, somewhat glossy, woody testa, light-brown raphe, and bearing the shallow impressions of the mace. The nutmegs of our commerce are deprived of the testa or shell, oval or ovate in shape, an inch or less in length, and marked on the broad end with a circular scar, from which proceeds a shallow furrow to a deeper depression near the upper end. The entire surface is reticulately furrowed, and of a light-brown color, or covered, particularly in the furrows, with a white powder (lime). The embryo is located near the base in a small conical cavity of the albumen or endopleura, which constitutes the remainder of the commercial article, is of a pale brownish-yellow color, has a fatty lustre, and is dissected by numerous curved channels filled with brown tissue and penetrated by the inner seed coat (tegmen). Nutmegs have a strong and pleasant aromatic odor, and a warm, aromatic, somewhat bitter taste.

The Penang and Singapore nutmegs are unlimed; the Dutch are limed.

False Nutmegs.—The *long*, *wild*, or *male* nutmeg resembles the foregoing, but is oblong, about 1½ inch long; the mace inodorous, less deeply lobed, the kernel of a paler color than nutmeg, and scarcely aromatic. It is obtained from *Myristica fatua*, Houtt., and is rarely seen in our commerce.

The so-called *California nutmeg* is the seed of *Torreya californica*, Torr., s. *T. myristica*, Hook. *Nat. Ord.* Coniferæ, *subord.* Taxineæ. It is oblong, with a smooth, brownish, thin testa, inclosing a kernel of the same shape, which has upon cross section a marbled appearance similar to that of the nutmeg, but has a terebinthinate odor and taste.

Fig. 114.



Wild Nutmeg with Mace.

Constituents.—Nutmegs contain about 2 to 3 per cent. of volatile oil (see Oleum myristicæ), between 25 and 30 per cent. of fat (see Oleum myristicæ expressum), some starch, protein compounds, and other principles of no medicinal importance.

Off. Prep.—Acetum opii, Pulv. aromaticus, *U. S.;* Pulv. catechu comp., Pulv. cretæ aromaticus, Spiritus armoraciæ comp., *Br.;* Spiritus (tinctura) lavandulæ comp., *U. S.*, *Br.;* Syrupus rhei aromat., Trochisci magnesiæ, Troch. sodii bicarbonatis, *U. S.*

Medical Action and Uses.—Observations and experiments upon man and animals agree in showing that nutmeg has a narcotic and intoxicating power. It is but little used as a medicine, except for flavoring purposes, but extensively as a condiment to qualify the action of oleraceous vegetables, soups, and pastry. It may be given in cases of simple debility of the stomach in *doses* of from five to twenty grains.

MYROBALANUS.—MYROBALAN.

Myrobalans, E., Fr.; *Myrobalanen*, G.

The fruit of several species of Terminalia, *Lin.* (Myrobalanus, *Gaertn.*).
Nat. Ord.—Combretaceæ.

Origin.—The following species yield myrobalans: Terminalia chebula, *Retz*, T. bellerica, *Roxb.*, T. citrina, *Roxb.*, and perhaps others. They are large trees, indigenous to India, with coriaceous entire and alternate or nearly opposite leaves, decandrous whitish or yellowish racemose flowers and one-seeded drupaceous fruits.

Description.—The following varieties have been distinguished:—

1. MYROBALANI CHEBULÆ.—They are nearly 1½ inch long and 1 inch thick, oblong or pyriform in shape, obtusely 5-angled and 5-ribbed, blackish-brown, the endocarp pale brown and resinous dotted, and contain a white seed.

2. M. BELLERICÆ.—They are roundish-oval, of about the size of a nutmeg, narrowed below, indistinctly 5-angled, reddish-brown, covered with a soft brownish tomentum, and contain a pale brown endocarp, inclosing the ovate and obtusely triangular seed.

3. M. CITRINÆ.—These are 1½ inch long, oblong, obtusely 5-angled, ribbed, orange- or ochrey-yellow, smooth, with a pale brown acutely angular endocarp, and a cylindrical seed.

4. M. NIGRÆ, s. INDICÆ.—These are unripe fruits, varying in size and shape, blackish-gray, and with an undeveloped seed.

5. M. EMBLICÆ.—These are obtained from Emblica officinalis, *Gaertn.*, s. Phyllanthus emblica, *Lin.*, a euphorbiaceous tree of India, and consist of subglobular drupaceous six-grooved capsules, which contain in each of the three cells two triangular red-brown seeds.

Constituents.—The astringent taste of myrobalans is due to tannin; Stenhouse (1843) found in the first variety also gallic acid, mucilage, and brown-yellow color. The last variety contains notable quantities of sugar. According to Hennig (1869), myrobalans yield about 45 per cent. of tannin, which is obtainable in the same manner as from nutgalls and at a lower price, owing to the cheapness of the drug.

Allied Species. TERMINALIA CATAPPA, *Lin.*—Its seeds resemble almonds, are edible, and yield about 50 per cent. of a bland fixed oil. The bark is very astringent.

TERM. BENZOIN, *Lin. fil.*, s. T. angustifolia, *Jacq.*—The resinous exudation is fragrant and resembles benzoin in properties.

Medical Action and Uses.—These fruits are now wholly disused in medicine, although they were once held in high esteem. Pliny speaks of one species as an astringent in diarrhœa and menorrhagia, and as a vulnerary. The Arabian physicians abound in their praise. Some species appear to have been cholagogue and others astringent. Rhazes declares that they act as emetics and cathartics, purge away the excrement, remove humidity, strengthen the senses and the understanding, are useful in cutaneous eruptions, colic, mental debility, obstinate fevers, headache, dropsy, and splenic disorders. Mesue embellishes this statement by adding, among other things, "that they restore youth, improve the complexion, the breath, and the perspiration, impart joy and hilarity," etc. They continued to be used by European physicians as late as the last century

MYRRHA, *U. S.*, *Br.*—MYRRH.

Gummi-resina myrrha.—*Myrrhe*, Fr., G.

A gum-resinous exudation from Balsamodendron Ehrenbergianum, *Berg*, perhaps, also, from Balsamodendron myrrha, *Nees.* Plant. Med., plate 357; Berg and Schmidt, Off. Gew., t. 29; Bentley and Trimen, Med. Plants, 59.

Origin.—Myrrh is collected from large shrubs or small trees, growing in Southern Arabia, by the Somalis, who cross the Gulf of Aden for the purpose. It is likely that it is obtained from both species mentioned above, which were collected by Ehrenberg (1820–1826) on the eastern side of the Red Sea, and on the first mentioned of which he observed the exudation of myrrh. But the principal supply of myrrh comes from Eastern Africa from the country of the Somalis, and is probably obtained from *B. opobalsamum*, Kunth, which grows northward into Abyssinia, and by Oliver and Bentley is considered identical with Berg's plant. Formerly, myrrh entered commerce through Egypt and the ports of the Levant, hence the term *Turkey myrrh;* at present, it is taken from Aden and Berbera to Bombay, where it is assorted before being shipped to Europe and America. From the observations of Marchand (1866), it seems to be chiefly produced in the bark, and to a small extent in the pith.

Description.—Myrrh is in roundish or irregular tears, or in larger masses having an uneven surface of a lighter or darker reddish-brown color and dull dusty appearance. These break readily with an uneven somewhat splintery fracture, which is of a waxy lustre, apparently fatty to the touch, often marked with semicircular whitish lines, of a brownish-yellow or reddish color, and translucent, at least when in thin layers. In cold weather, myrrh may be readily powdered, but in warm weather, it cannot be reduced to a fine powder until after it has been well dried and deprived of some volatile oil. When triturated with water, it yields a brown-yellow emulsion. Alcohol dissolves it partly, leaving the gum behind and yielding a brownish orange-colored tincture. It has a peculiar rather agreeable odor, and an aromatic, acrid, and bitter taste.

Other Varieties of Myrrh.—According to Vaughan (1853), there are two other varieties of myrrh found in the Arabian commerce at Aden; one called by the Arabs *mur*, or by the Somalis *heera bôl*, by which names African myrrh is likewise known, resembles the latter in all sensible properties, but upon the fractured surface is destitute of the whitish lines and dissolves in alcohol only to the extent of 25 per cent. (*Pharmacographia.*) The other variety is known as *bissa bôl*, or by the Somalis as *hebbakhade.* Hanbury (1853) states that it is the *Myrrha indica* of Martiny, and was formerly, but is not now, distinguished in commerce as *Indian myrrh;* it has the appearance of an inferior dark-colored myrrh, and is chiefly distinguishable by its different odor, which is likened to that of mushrooms.

Admixtures.—Myrrh is not unfrequently mixed with dark-colored pieces of various gums, some of which merely swell with water, and with *East India bdellium.* The latter is referred to *Balsamodendron mukul*, Hook., and, according to Dymock (1876), a similar exudation is yielded by *B. Roxburghii*, both species indigenous to India, but perhaps also growing in Southern Arabia. It is in large pieces, rounded and dusty on the surface, breaks with a flat conchoidal fracture, has a dark, sometimes blackish-brown color, is translucent in thin layers, and has an odor somewhat resembling myrrh; its tincture does not acquire a purplish color on the addition of nitric acid.

Constituents and Tests.—Myrrh contains a small quantity of volatile oil which may reach 2 or $2\frac{1}{2}$ per cent., from 25 to 40 per cent. of resin, 40 to 65 (or, in Arabian myrrh, 75) per cent. of gum, and yields about $3\frac{1}{2}$ per cent. of ash, mostly $CaCO_3$. *Oil of myrrh* is a pale yellow, thick liquid, of specific gravity 0.98, but, according to Brandes (1819), sometimes heavier than water.

The variable yield is explained by Bley and Diesel (1845) by oxidation, whereby formic acid is formed. For the same cause, probably, the composition may vary; Ruickholdt (1845) obtained results leading to the formula $C_{10}H_{14}O$, which would make it isomeric with thymol and carvol; Heldt (1847) found $C_{22}H_{32}O_2$; Buri (*Pharmacographia*) obtained $C_{22}H_{32}O$. Dissolved in bisulphide of carbon, the oil gradually assumes a permanent violet or blue color after the addition of nitric acid or bromine. The *resin* is entirely soluble in alcohol, ether, and chloroform. Hager (1865) found it only partly soluble in bisulphide of carbon, the soluble portion acquiring a violet color with nitric acid. Muriatic acid produces the same color with the resin, after previously moistening it with alcohol. The *gum* consists, according to Hekemeijer (1858), of two kinds, one being precipitated by neutral, the other by basic acetate of lead. Shuttleworth (1871) recommends it as making a good paste of unlimited keeping qualities; its adhesiveness is increased by the addition of a little molasses.

Allied Drugs.—BALSAMUM GILEADENSE, *Balm of Gilead, Mecca balsam,* or *Opobalsamum,* though differing greatly from myrrh, is referred to Balsamodendron opobalsamum, *Kth.* It is said to exude spontaneously, and is an opaque yellowish or whitish, fragrant, viscid liquid, in which Trommsdorff found 30 per cent. of volatile oil and 64 per cent. of hard resin, while Bonastre obtained only 10 per cent. of volatile oil, 70 per cent. of adhesive, and 12 of hard resin. It is at present rarely, if ever, met with in our commerce.

BDELLIUM.—Indian bdellium is described above. African bdellium is the exudation of Balsamodendron Africanum, *Arn.*, a shrub indigenous to West Africa, and is used in France chiefly as an addition to some plasters. It is met with in irregular roundish or oval tears, about an inch in diameter, and varying in color from pale yellowish to brown-red. It is translucent, breaks with a waxy fracture, and resembles myrrh in odor and taste, but its tincture does not become purple on the addition of nitric acid.

Off. Prep.—Decoct. aloes comp., *Br.;* Mistura ferri comp., Pilulæ aloes et myrrha, *U. S., Br.;* Pil. ferri comp., *U. S.;* Pil. galbani (assafœtidæ) comp., Pil. rhei comp., Tinct. myrrhæ, *U. S., Br.;* Tinct. aloes et myrrhæ, *U. S.*

Medical Action and Uses.—Myrrh is both stimulant and tonic. In small doses it appears to quicken the appetite and digestion; in larger doses it irritates the stomach, occasioning nausea and even vomiting and diarrhœa, quickening the pulse, stimulating the bronchial mucous membrane, and probably exerting a special influence of the same sort upon the uterine system. It has been found useful in *atonic dyspepsia* with flatulence, mucous evacuations, constipation, and associated nervous disorders of an hysterical or hypochondriacal description. In such affections it is profitably associated with vegetable bitters and iron. The compound iron mixture is a valuable preparation of this nature, which is extensively employed in *amenorrhœa* connected with anemia and general torpor of the functions. Myrrh is especially useful in *chronic bronchitis* with profuse expectoration, but if fever is present its dose should at first be small. In like manner it may be employed in chronic uterine and vaginal *leucorrhœa.* In ancient times it was much used as a vulnerary to promote the healing of *wounds, ulcers,* etc., of an indolent type. Its stimulant and astringent qualities are manifested in cases of *spongy* and *ulcerated gums.* Its *dose* is from five to thirty grains; but it is seldom used in substance. It may be prescribed in emulsion as an enema.

NAPHTHALINUM.—NAPHTHALIN.

Naphthalene, E.; *Naphtaline, Naphtalène,* Fr.; *Naphtalin, Naphtalen,* G.
Formula $C_{10}H_8$. Molecular weight 128.

Origin.—Naphthalin was discovered by Garden (1820) in coal-tar oil, and recognized by Reichenbach as resulting from the decomposition of the products of distillation of coal. It has since been obtained from a large number of organic bodies, particularly if the distillation products are conducted through a red-hot tube.

Preparation.—Coal-tar oil is distilled, and that portion collected by itself which passes over between 170° and 200° C. (338° and 392° F.), or the distillation is continued until the contents of the retort begin to char. The dark-colored product is purified by resubliming it two or three times.

Properties.—Naphthalin forms large, colorless and transparent, glossy laminæ, which have a faint and peculiar odor. According to Kopp (1855) it fuses at 79.2° C. (174.6° F.), forming a colorless liquid, and crystallizes again on cooling. It volatilizes slowly at the ordinary temperature, and boils at 218° C. (424.4° F.). When heated in the air, its vapors are ignited with difficulty, and burn rapidly with a red and sooty flame. It is insoluble in water, freely soluble in hot alcohol, in ether, bisulphide of carbon, chloroform, and in warm fixed and volatile oils. On dissolving it together with picric acid in hot alcohol, the two compounds unite, forming, on cooling, golden-yellow needles, having the composition $C_{10}H_8.C_6H_3(NO_2)_3O$, and yielding all the picric acid to ammonia. Naphthalin yields with chlorine and bromine numerous products of addition and substitution. When treated with strong nitric acid, *nitronaphthalins* are generated, which, by the action of reducing agents, are converted into *naphthylamina* $C_{10}H_7.NH_2$, which is crystallizable, turns red in the air, and the salts of which yield blue, and finally purple-colored precipitates with ferric chloride, chromic acid, and other oxidizing agents.

Medical Action and Uses.—Upon the tongue it gradually develops a strong, acrid, burning taste in the whole mouth and throat, and the expectoration of ropy or frothy sputa. It has been employed with reputed advantage in *chronic bronchitis* and *bronchorrhœa*, particularly as they occur in advanced life. In other words, its operation in these affections is the same as that of terebinthinate and balsamic medicines. Externally, dissolved in alcohol, it has been applied as a substitute for tincture of camphor in *sprains*, *contusions*, etc., and in the treatment of scaly *eruptions of the skin*. It is a valuable agent in preventing the ravages of moths, book-worms, etc., and has been administered internally for *intestinal worms*. The *dose* is from eight to thirty grains, given in some aromatic and alcoholic vehicle. An ointment is made with thirty grains of naphthalin to an ounce of lard.

NARCISSUS.—DAFFODIL.

Narcisse des près, *Porrillon*, Fr.; *Gelbe Narcisse*, G.

Narcissus pseudonarcissus, *Lin.* *Nat. Ord.*—Amaryllidaceæ.

Description.—Daffodil is found wild in moist and shady places in Southern Europe, and is frequently cultivated in gardens. It has an ovate, tunicated, whitish *bulb*, which is covered by brown leaf-scales, and has a mucilaginous and bitter taste. The *leaves* are flat, linear, erect, a foot long, and one-third of an inch broad. The *flowers* are single on the scape, nodding, large, yellow, with a top-shaped tube, and a large, bell-shaped cup, wavy or crisped at the margin, and equal to the six spreading divisions of the perianth; they have an unpleasant odor, and a nauseous, bitter, and acrid taste.

Constituents.—The acrid and bitter principles of daffodil have not been investigated. Caventou obtained from the flowers, by ether, a yellow, and, by alcohol, a brown-yellow coloring matter.

NARCISSUS JONQUILLA, *Lin.*, *Jonquil.*—The scape bears two to five small, yellow, fragrant flowers, from which ether takes up a yellow, butyraceous, volatile oil of a very agreeable odor; afterwards alcohol dissolves a brown, viscid oil of an unpleasant odor. (Robiquet, 1835.)

Medical Action and Uses.—The several species of narcissus appear to possess almost identical qualities. Pliny describes their emetic, purgative, maturative, and cicatrizing powers, and refers also to their soporific virtue, saying that the plant was called narcissus, because it was narcotic, and not after the fabled boy: "et a narce narcissum dictum, non a fabuloso puero." The Arabian writers dwell especially upon its emetic properties and its stimulant virtues exhibited in curing alopecia, producing abortion, and exciting genital erections by its local irritation. According to Orfila's experiments upon dogs, the flowers and the bulb are local irritants, internally causing vomiting, purging, and inflammatory gastro-intestinal lesions. Applied to wounds the extract inflames them, and produces all of the above effects, besides affecting the brain and the whole nervous system, causing staggering, anæsthesia, paralysis, and death by paralysis of the lungs and heart. In man the most noticeable effect of narcissus is vomiting. From fifteen to thirty grains of wild narcissus flowers are said to act as an emetic, especially if given in a decoction prepared from the flowers dried slowly in the sun. Quite recently (1876) the infusion has been strongly recommended for children when prepared in the following manner: From thirty to fifty grains of narcissus flowers are infused for fifteen or twenty minutes in five or six ounces of hot water, and strained. When slightly sweetened, children take it without repugnance, and vomit within ten or twelve minutes. The emetic action of narcissus has been used to break up *intermittent fever*, and relieve *bronchial catarrh*, with congestion or obstruction of the air-tubes. Like ipecacuanha, it has also been used in *dysentery*, especially of the epidemic form. Its influence on the nervous system is attested by the vogue it has enjoyed in *hysteria*, *chorea*, *whooping-cough*, and even *epilepsy*. The *dose* of the powdered flowers is from fifteen to thirty grains; of the powdered bulb from thirty grains to two drachms may be given as an emetic.

NASTURTIUM.—WATER-CRESS.

Cresson de fontaine, Fr.; *Brunnenkresse*, G.

Nasturtium officinale, *R. Br.*, s. Sisymbrium nasturtium, *Lin.*, s. Cardamine fontana, *Lam.*

Nat. Ord.—Cruciferæ, Siliquosæ.

Description.—The true water-cress is a perennial herb, growing in springs, brooks, ponds, and ditches in Europe, Asia, Africa, and North America. The ascending and spreading stem is 1 or 2 feet long, angular, and hollow. The leaves are petiolate, 2 or 3 inches long, dark green, pinnate, with from 5 to 15 obliquely ovate or roundish oblong leaflets, about $\frac{3}{4}$ inch long, or sometimes much smaller, the terminal one being largest, ovate-cordate or oblong, and rather wedge-shaped at the base. The flowers are in loose corymbose racemes, white, and produce linear ascending pods, about $\frac{1}{2}$ inch long. The fresh plant bruised has a pungent odor, and a bitterish somewhat biting taste.

Constituents.—On distilling the fresh plant with water a volatile oil is obtained, which contains sulphur, and is probably identical with oil of mustard.

NASTURTIUM SYLVESTRE, *R. Br.*, with narrow linear pods, and

NAST. PALUSTRE, *D. C.*, with oblong or ovoid pods, have similar properties. Both species grow in North America (the former one as an introduced plant), have pinnatifid toothed leaves, and small yellow flowers.

Medical Action and Uses.—Like several other plants that have a pungent taste, as scurvy-grass (Cochlearia officinalis) and horse-radish (C. armoracia), water-cress has long been celebrated as a purifier of the blood, and was and is used in the spring to eliminate the crude humors accumulated during the winter. That it increases the appetite, renders the bowels freer, and the urine more abundant, is familiarly known. It is a favorite and efficient domestic remedy in many cases of glandular *scrofula* in children, and applied in a poultice to *eczematous* eruptions it sometimes effects a cure. It is also reputed to do good in chronic *bronchitis*. It is best eaten fresh as a salad; but it may be given in decoction or infusion, or its expressed juice may be taken in milk.

NECTANDRA, *U. S.*—BEBEERU BARK.

Nectandræ cortex, Br.; *Cortex beberu, s. bibiru.—Greenheart bark*, E.; *Écorce de bébéeru*, Fr.; *Bibirurinde*, G.

The bark of Nectandra Rodiæi, *Schomburgk*. Hooker's Jour. Bot., 2d ser.; Bentley and Trimen, Med. Plants, 219.

Nat. Ord.—Lauraceæ.

Origin.—The greenheart is a tree about 30 feet high, growing in British Guiana on hillsides a short distance from the sea, and disappearing further inland. The small compound racemes of white flowers are situated in the axils of the coriaceous oblong elliptical and acuminate leaves, and produce a subglobular berry about 2 inches in diameter, supported by the enlarged cup-shaped tube of the calyx, and containing a single seed, nearly the size of the fruit. The wood is very durable and useful in shipbuilding.

Description.—The bark is in flat or somewhat curved pieces, sometimes 1 or 2 feet long, and 4 or 6 inches wide, by $\frac{1}{4}$ inch thick, is heavy, hard, and brittle, and consists of liber only. The outer surface is gray-brown, with numerous irregular conchoidal depressions, the ridges between consisting of soft cork, sometimes with light reddish-gray patches, containing small suberous warts. The inner surface is cinnamon brown, and rather coarsely striate. The bark breaks with a short and rough granular fracture, which is somewhat fibrous in the inner layer. It has no odor; its taste is astringent and persistently bitter.

Constituents.—Besides tannin, producing green precipitates with iron salts, some starch and other common constituents; the bark contains an alkaloid, *beberina*, $C_{18}H_{21}NO_3$, discovered by Rodie (1834). In its pure state it is a white bitter fusible powder, soluble in alcohol and ether, according to Walz (1860), identical with *buxina*, the alkaloid of *Buxus sempervirens*, Lin., and according to Flückiger (1869), also with *pelosina*, the alkaloid of pareira brava. The commercial sulphate of beberina (see page 270) was found by Maclagan (1843) to contain another alkaloid, *sipirina*, which is red-brown, resin-like, and insoluble in ether. Maclagan obtained the alkaloid also from the fruit, which in addition contains *bebiric acid*, forming white deliquescent crystals, fusible at 150° C., and sublimable at 200° C. Together with Gamgee (1870), he examined the wood, and obtained several alkaloids, one of which, *nectandria*, $C_{20}H_{23}NO_4$, fuses in boiling water, is very soluble in chloroform, little so in ether. The others have not been further examined.

Pharmaceutical Uses.—For the preparation of Beberiæ sulphas, *Br.*

Medical Action and Uses.—The bitterness and astringency of nectandra are due in a great measure to its alkaloid, *beberia* or *bébéerine*. According to its original promoters, beberia had all the virtues without the objectionable qualities of quinia, such as the production of tinnitus, headache, etc. In small doses it appeared to be a stomachic tonic. Experiments upon the frog, in which the alkaloid was used hypodermically, produced tetanic retraction of the limbs in the same manner as quinia; but these effects were not produced by either substance when given by the stomach. Nor did the tetanism resemble that of strychnia, since it was not intensified by external excitation.

The treatment of *periodical fevers* by this substance proves it to be a very imperfect substitute for quinia, since it fails in at least one-half of the cases. It has also been vaunted in the treatment of periodical *headaches* and *neuralgias*, as an anti-hectic remedy in *consumption*, as a tonic in *atonic dyspepsia*, in *menorrhagia*, *leucorrhœa*, etc. It may, on the whole, be regarded as an imperfect substitute for quinia. The *dose* of beberia is from one to three grains as a tonic, and from five to ten grains as an antiperiodic medicine. (See Beberia sulphas.)

NIGELLA.—FENNEL FLOWER.

Faux cumin, Fr.; *Schwarzkümmel*, G.

The seeds of Nigella sativa, *Lin.*, and of Nig. damascena, *Lin.*
Nat. Ord.—Ranunculaceæ, Helleboreæ.

Origin.—Both plants are annuals, indigenous to Southern Europe and the Levant. They have finely divided leaves like fennel; the second species also a similar involucre. The fruit consists of 5 united follicles, which contain numerous seeds. Both plants are cultivated in gardens, and are known respectively as *nutmeg flower* and *ragged-lady*.

Description.—The seeds are about $\frac{1}{10}$ inch long, triangular-ovate, netted-wrinkled, of a dull black color, internally white, contain a fleshy albumen enclosing a small straight embryo, and have a somewhat acrid taste. When rubbed, the seeds exhale a peculiar odor; that of the first species being camphoraceous, and resembling cajuput, while that of the second species resembles the odor of strawberries. The latter are sometimes sold as *magnolia seeds.*

Constituents.—Reinsch obtained 35 per. cent. of fixed oil, which, according to Lepine, is orange-yellow, and solidifies at 2° C. (35.6° F.). The volatile oil is lighter than water, colorless, and shows a blue fluorescence. Reinsch's *nigellin* is an extract-like yellow mass, having the consistence of turpentine and a bitter taste.

Medical Action and Uses.—Nigella is closely analogous in its properties to coriander, anise, and cumin, and like them is used in the East as a condiment for food, and medicinally as a carminative, aphrodisiac, emmenagogue, galactogogue, diuretic, and expectorant.

NITROBENZOLUM.—NITROBENZOL.

Nitrobenzol, Fr., G.; *Essence de mirbane*, Fr.
Formula $C_6H_5NO_2$. Molecular weight 123.

Preparation.—Benzol is added in small portions to warm fuming nitric acid, when a violent action takes place, and a dark-red liquid is formed, which is mixed with water, and the oily precipitate washed with the same liquid.

Properties.—Nitrobenzol is a yellowish, oily liquid, having the spec. grav. 1.209, crystallizing in needles at 3° C. (37.4° F.), and boiling at 213° C. (415.4° F.). It has a strong odor of bitter almonds—hence the incorrect name *artificial oil of bitter almonds*—a sweet taste, and dissolves in concentrated sulphuric and nitric acid, and in all proportions in alcohol and ether. In its alcoholic solution it is readily converted into anilina through the influence of nascent hydrogen.

Pharmaceutical Uses.—Nitrobenzol is often used for scenting soaps and in various perfumes as a tolerably good substitute for the more costly oil of bitter almonds, which is sometimes adulterated with it (see Ol. amygd. amaræ); but its most important use is in the manufacture of anilina (see page 175).

Physiological Action. *On Animals.*—The experiments of Dr. Letheby and others show that the toxical phenomena vary not only with the dose of this poison, but very singularly in the time of their coming on, so that several or even many hours may elapse before they appear. When the poison is speedily fatal, the animal is affected with giddiness, inability to walk, complete loss of voluntary power, occasional spasms of the dorsal muscles, or general epileptiform convulsions; the pupils are widely dilated, the heart's action tumultuous or irregular, and the breathing difficult. The animals retain consciousness until life is extinct. When the action of poison is slower its visible effects may be delayed even for days, and then suddenly there is observed a look of distress, perhaps vomiting, and a fit of epilepsy, followed by exhaustion and then by renewed fits, which occur at irregular intervals for several days; between them the limbs are in constant motion. Consciousness is unimpaired. Death takes place through exhaustion, or gradually voluntary power is restored, and the animal recovers. The post-mortem appearances consist of extreme congestion of the bloodvessels of the brain and its membranes; the cavities of the heart and the veins being full of black, coagulated blood; the lungs are congested in a less degree; but there is no sign of gastric lesions.

On Man.—Numerous cases have been published of poisoning by nitrobenzole, sometimes by its being swallowed, sometimes by the inhalation of its fumes, and sometimes by its application to the skin. A remarkable illustration of the potency of this poison is furnished by several cases of females affected by the odor of the so-called "almond glycerin soap," and by that of a person who, while using such a soap in a warm bath, fainted from the effects of nitrobenzole set free by the heat, and was ill for some time afterwards. A case is also recorded of a man who, having used a liniment containing this product in the treatment of scabies, became partially paralyzed, while his head was drawn back, and his face, hands, mouth, and pharynx were all cyanosed, and the breath and matters vomited smelled of bitter almonds. In this case, as in some others, the blue tint remained for at least a week. The symptoms produced in man are identical with those observed in animals, except the purple color of the skin, which appears to be due in part to venous congestion, but in part also to the presence of aniline derived from the decomposition of nitrobenzole in the body. The mode of death and the lesions found *post-mortem* are also essentially the same as in animals: the tarry dark blood, congested lungs, heart, and brain, etc. In one case the liver is described as being of a deep-purple color. Whether recovery or death occur, the peculiar odor of nitrobenzole persists for many days. The probable fatal dose of nitrobenzole may be stated to be between a few drops and two drachms.

Medical Uses.—The only disease, so far as we are informed, in which the preparation has been used is *scabies*, but its dangerous effects from accidental conditions, and the case of poisoning by it in this very disease, and to which reference has been made, ought to exclude it altogether from medical practice.

In poisoning by nitrobenzole the proper remedies consist of stimulants, internally and externally; carbonate of ammonia rather than alcohol, electricity, the hot bath, and a simultaneous cold douche upon the head and spine, frictions of the skin, etc.

NITROGENII MONOXIDUM.—NITROUS OXIDE.

Laughing gas, E.; *Oxyde nitreux*, *Protoxyde d'azote*, Fr.; *Stickstoffoxydul*, *Lachgas*, G.

Formula N_2O. Molecular weight 44.

Preparation.—Nitrate of ammonium, which is absolutely free from chloride, is gradually heated to about 200° C. (392° F.), when the decomposition commences and the heat may be slowly increased. The salt yields then water and nitrous oxide without other products of decomposition; NH_4NO_3 yields $2H_2O$

$+N_2O$. The gas is passed through a little warm water, which will retain any undecomposed salt or other product, without retaining much of the gas. For other precautions in the preparation of this gas, refer to the decomposition of Ammonii nitras, on page 159.

Properties.—Nitrous oxide is a colorless gas, of a very slight agreeable odor and a sweetish taste. It has the specific gravity 1.6 (Dalton), and a liter of it at 0° C. (32° F.) weighs 1.97 grams. It is not inflammable, but supports the combustion of ignited bodies, which burn more vigorously than in the open air. By the aid of pressure and cold, it may be condensed into a thin, very mobile, colorless liquid, which, at a temperature of about —100° C. (—148° F.), congeals to colorless crystals. The gas is soluble in water, alcohol, ether, volatile and fixed oils.

Nitrous Oxide Water.—The solubility of nitrous oxide in water has been determined by Carius (1855) as follows: Water absorbs at a barometric pressure of .76 meter and at a temperature of

0°	5°	10°	15°	20°	25° C.
1.3052	1.0954	.9196	.7778	.6700	.5962 measures of the gas.

Such an aqueous solution, prepared under a pressure of about five atmospheres, has been employed under the name of *oxygenous aërated water.*

Physiological Action.—The primary action of nitrous oxide gas is to stimulate the whole system; a tingling sensation is felt all over the body, the senses seem unnaturally acute, the pulse becomes stronger and more frequent, the breathing more rapid and shallow, and the face grows pale. If the inhalation is interrupted at this period, a lively intoxication is developed. It was formerly the custom to have semi-public exhibitions of this appropriately called "laughing gas," in which one of the most familiar phenomena was a high degree of mental excitement, generally exhibited in rhapsodical declamation or singing, but sometimes, also, in a sudden fit of violent pugnacity, which subsided abruptly when the vapor was exhaled. But if the inspiration is not interrupted, the breathing, in about a minute and a half, begins to be stertorous; at the same time, the pallor of the face is replaced by a cyanotic hue, and complete unconsciousness and anæsthesia. Without a renewal of the inhalation, it does not last more than a minute or two. Unlike ether or chloroform, it is apt to occasion muscular twitching or even rigidity. In general, feeble persons are more quickly affected than the strong; children, females, and the aged more speedily than adult males.

The number of deaths due to the administration of this gas is surprisingly small when compared with those following chloroform and even ether, and, as in the case of the latter agent, they may always, or nearly so, be demonstrably ascribed to the special condition of the patient or the mode of administration, and not to the anæsthetic itself. According to the statistics of Darin, 53 deaths occurred in 152,260 administrations of chloroform, or 1 : 2872; 4 in 92,815 of ether, or 1 : 23,203; and 3 in 300,000 of gas, or 1 : 100,000, one of which was due to an accident, namely, the falling of a cork into the air-passages. Other ill effects have occasionally been noticed, *e. g.*, coma of several days' duration, hemiplegia, temporary catalepsy or hysteria, clonic convulsions, etc.

The mode in which nitrous oxide gas acts has been variously explained, and while it remains as difficult as ever to understand its soporific and anæsthetic power, it is very easy to refute the principal error in regard to it, which is that it is merely an asphyxiating agent whose action consists in excluding the atmosphere from the lungs. This simple, but very absurd, hypothesis would liken the presence of the gas in the air-passages to that of a foreign body, or, more precisely, to that of an unirritating but irrespirable gas. But carbonic acid is such a gas, and, although it may prove fatal, it does not produce the discoloration of the skin which is characteristic of nitrous oxide. Besides, nitrous oxide is not irrespirable. The experiments of Zimmermann show that rabbits and pigeons may be confined in it not only for minutes, but for hours, and yet return to active life. It must not be forgotten that it not only contains oxygen, but a far larger proportion of it than exists in atmospheric air; and that very possibly a portion of the gas is decomposed, furnishing an amount of oxygen necessary to maintain life, while the bulk of it remains unchanged and induces cyanosis, unconsciousness, and anæsthesia. This conjecture is not a mere hypothesis, for it is established by experiment that venous blood introduced into an atmosphere of nitrous oxide assumes the arterial color; that phosphorus undergoes oxidation in it; that seeds germinate and grow in it; and, above all, that it does not put out the light of a burning taper. Finally, a most important, and, indeed, capital fact is, that in the series of phenomena which it produces in animals immersed in it, the organ which remains longest in action is the heart; and as the gas is very rapidly eliminated from the system, the brain and the lungs are soon relieved from its influence, while the heart continues to pulsate, and repair whatever temporary damage may have been produced.

Surgical Uses.—Nitrous oxide has been used in surgical operations, but chiefly in those requiring a comparatively short time for their performance. *Teeth* have been extracted with its aid in cases innumerable in this country and in Europe; and whoever has experienced its effects must be satisfied with the efficiency and convenience of its use. All surgical operations which can be quickly completed, from the opening of *abscesses* to the operation for *cataract*, have been successfully performed with its aid; and in numerous instances it has sufficed for operations lasting from fifteen to twenty minutes.

Administration.—The nostrils being closed, the gas may be inspired from the reservoir in which it is collected, or from caoutchouc bags, through a tube and mouth-piece furnished with valves opening outwards, to permit the breathed air to escape during expiration. It is also kept in wrought-iron vessels in a highly condensed or even a liquid state, and may thus be conveniently transported from place to place.

NITROGLYCERINUM.—NITROGLYCERIN.

Trinitroglycerin, Glonoin.

Formula $C_3H_5(NO_2)_3O_3$. Molecular weight 227.

Preparation.—Nitroglycerin was discovered by Sobrero (1847), and is at the present time prepared on a large scale by slight modifications of the process proposed by the discoverer and by E. Kopp. To about seven pounds of a mixture, composed of one part of nitric acid, sp. gr. 1.47, and two parts of strong sulphuric acid, one pound of glycerin is slowly added, with frequent stirring, and with the precaution of preventing the temperature from rising above 26.6° C. (80° F.). The mixture is then poured into a large quantity of water, and the oily sediment well washed with a diluted solution of alkali and of water.

Properties.—Nitroglycerin is a colorless or pale-yellowish oily liquid, having the density 1.60 at 15° C. (59° F.), and, when exposed to a low temperature, crystallizes in long needles. It is without odor, but its vapors produce intense headache; its taste is sweet, and pungently aromatic. When ignited in the open air it burns quietly and incompletely; but when heated in closed vessels, or by percussion, it explodes with great violence. On keeping it is gradually decomposed, oxalic acid being formed, besides nitrous acid and other gases, from the pressure of which explosions are apt to occur. Nitroglycerin forms the basis of various blasting compounds known as *dynamite*, *glyoxylin*, *dualin*, etc. It is nearly insoluble in water, but dissolves freely in ether, alcohol, and methylic alcohol; these solutions will likewise explode by percussion with a wet hammer.

Physiological Action.—Nitroglycerin is a powerful poison, and exerts a marked effect upon the nervous system even when given in minute doses. Its general effects may be summarily described as "accelerated respiration, paralysis, loss of reflex action, and apparently to a great degree of sensation, and death from stoppage of the respiration." (Brunton and Tait.) In frogs it induces lethargy and paralysis, alternating with clonic and tonic convulsions; in cats and rabbits convulsions, tetanus, paralysis, spasmodic breathing; frequent and feeble pulse, general anæsthesia, and death; and in dogs the same effects, besides salivation and vomiting. On dissection the brain may be either pale or congested, and the lungs are engorged with blood, but the heart is empty.

Medical Uses.—When this preparation was first known it was for a short time employed in the treatment of certain functional nervous disorders, such as *asthma*, *epilepsy*, *headache*, etc., but it appears to be now entirely disused.

NUX VOMICA, *U. S.*, *Br.*—NUX VOMICA.

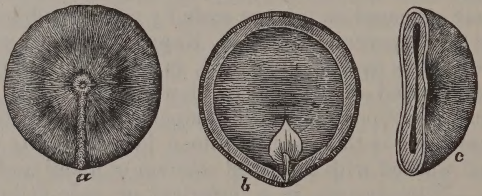
Semen strychni, P. G.; *Semen nucis vomicæ.—Poison nut*, *Quaker buttons*, E.; *Noix vomiques*, Fr.; *Krähenaugen*, *Brechnuss*, G.

The seeds of Strychnos nux vomica, *Lin.* Steph. and Church, Med. Bot., plate 52; Bentley and Trimen, Med. Plants, 178.

Nat. Ord.—Loganiaceæ.

Origin.—The tree has a short, thick, often crooked trunk, opposite, oval, glossy, 3- to 5-nerved leaves, and small, funnel-shaped, whitish flowers in small, terminal, paniculate cymes; the smooth, orange-colored berry is globular, about two inches in diameter, and contains about five seeds. The tree is common in many parts of Hindoostan, Farther India, some of the East India Islands, and as *St. lucida*, R. Br., is also found in Northern Australia. All parts of the plant possess a bitter taste, and are probably poisonous; the bark has at one time been sold in place of angustura bark (see page 174). The white, gelatinous pulp of the fruit, it has been stated, is eaten in India by birds; it, however, contains strychnia (*Pharmacographia*). The seed is the only officinal portion. The quantity imported into the United States amounts to about 450,000 pounds per year.

Fig. 115.



Nux Vomica.—*a.* Surface with raphe; *b.* Longitudinal section showing albumen and embryo; *c.* Transverse section showing central cavity.

Description.—Nux vomica is in the form of an orbicular disk, nearly an inch in diameter, and almost a quarter of an inch thick, nearly flat, or convex on one side and concave on the other, with the margin frequently thickened. The surface is of a grayish or greenish-gray color, and has a slight silky lustre from the closely appressed soft hairs, directed towards the circumference, and forming a soft ridge on the edge. Where the hairs have been rubbed off, the dull, brownish testa becomes visible. In the centre of the concave side is the hilum, connected by a slightly elevated raphe with the chalaza, which forms a small protuberance on the edge in the immediate vicinity of the radicle.

Schleiden, Berg, and others regard the latter as the hilum, and the central scar as the chalaza. The thin testa incloses a yellowish-gray, somewhat translucent, horny, and very hard albumen (endosperm), which is of the same form as the seed, but has within it a large, flat, circular cavity. After softening the seed in hot water, the edge may be readily trimmed down with a knife, and the albumen split into two disks, which were united with each other merely on the margin to the width of less than one-eighth of an inch. The embryo is over one-quarter of an inch long, has a thick, club-shaped radicle, and a pair of pale-greenish, delicately 7-nerved, heart-shaped cotyledons projecting into the circular cavity. The seed is inodorous, but possesses a persistently bitter taste.

Nux vomica is very difficult to powder, owing to the horny condition of the albumen. The powdering is considerably facilitated by drying the entire seeds for two or three days, and breaking them up into several pieces, which are again dried for several days by means of warm air, and then reduced to powder of the desired fineness. If a drug-mill, with chilled iron grinding plates, admitting of regulation as to different degrees of fineness, be used, much labor may be saved in the final powdering in an iron mortar, provided with a heavy iron pestle. Powdered nux vomica is of a light gray-greenish color.

Constituents.—The horny nature of nux vomica is probably due to protein compounds, of which it contains about 11.3 per cent. (*Pharmacographia*). Gummy matter, fat, sugar, and *igasuric acid*, besides the alkaloids, are also contained in it. The acid was discovered by Pelletier and Caventou (1819), and by Höhn (1873) was regarded as a kind of tannin; the latter obtained it as an amorphous, yellowish-white mass, of a strongly acid and somewhat astringent taste; its solution is colored dark green by ferric salts, precipitated yellow by acetate of lead, and rapidly reduces an ammoniacal solution of silver.

The alkaloids *strychnia*, *brucia*, and *igasuria*, are the medicinally important constituents of nux vomica. For an account of the first of these, which is present to the amount of $\frac{1}{4}$ or $\frac{1}{2}$ per cent., see the article Strychnia in this work.

Brucia, $C_{23}H_{26}N_2O_4$, seems likewise to vary in quantity; Merck obtained only 0.12, Wittstein 0.5, Mayer 1.10 per cent.; by the latter it was estimated by means of potassio-mercuric iodide, and the presence of igasuria was not taken into account. The alkaloid was discovered by Pelletier and Caventou (1819), in the false angustura bark, which was then supposed to be derived from *Brucea antidysenterica*, Mill., an Abyssinian shrub. It is one of the by-products of the manufacture of strychnia, and in the officinal process for this alkaloid, is obtained from the mother-liquor and alcoholic washings, by neutralizing them with sulphuric acid, evaporating to crystallization, removing the mother-liquor, purifying the crystals by treatment with animal charcoal, precipitating with ammonia, and recrystallizing from boiling 80 per cent. alcohol; it contains then $4H_2O$. It is soluble in 850 parts of cold water, 1.5 parts of alcohol, 7 parts of chloroform, and 70 parts of glycerin. It is soluble also in ammonia, creasote, very slightly so in volatile and fixed oils, and is insoluble in ether. It fuses without decomposition a little above 100° C., and at a higher heat burns, leaving voluminous charcoal. In contact with strong nitric acid, brucia acquires a blood-red color, which changes to orange, and finally yellow; if now stannous chloride be added a beautiful violet red is produced. The compound thus produced, according to Roehre (1878), may be obtained in crystals, which dissolve in water and mineral acids with a violet color. A compound of a similar color is obtained by using sulphurous acid, and lustrous brick-red needles are obtained by using ammonium sulphide in place of stannous chloride. These reactions are not interfered with by the presence of a little strychnia. Commercial brucia generally contains traces of strychnia, as proven by Cownley (1876), and Shenstone (1877), and according to the latter, may be completely freed from it by partial precipitation, brucia being precipitated from its solutions by strychnia.

Igasuria was discovered by Desnoix (1854) by concentrating the filtrate and washings of the lime precipitate in the decoction of nux vomica. The crystals thus obtained are stated by Schützenberger (1858) to be a mixture of not less than 9 different alkaloids, which he distinguished by prefixing to igasuria the letters *a*, *b*, *c*, etc. This subject requires further investigation. Igasuria has a bitter taste, and is poisonous.

Other Species of Strychnos.—The seeds of Str. tieute, *Lech.*, indigenous in Java, closely resemble nux vomica, but are smaller and whiter in color. The decoction of the root bark, evaporated to an extract, is the principal ingredient of the arrow poison, *upas-tieute.* It contains strychnia.

The seeds of Str. potatorum, *Lin.*, indigenous to India, are subglobose, ½ inch or less in diameter, brownish-gray in color, and of an insipid, not bitter taste. They do not contain strychnia, and are used in India as *clearing nuts*, for cleansing muddy water, also in diabetes, and as an emetic. In 1871 they were sent to the United States as *Indian gum nuts.*

See Ignatia, page 739.

Off. Prep.—Extract. nucis vomicæ, Tinct. nucis vomicæ, Strychnia, *U. S.*, *Br.*

Medical Action and Uses.—The action and uses of nux vomica being identical with those of strychnia, they will be treated of in connection with the latter. It may be mentioned in this place, however, that the activity of nux vomica is too variable to render it eligible as a medicine. It may be prescribed in the *dose* of from one to five grains three times a day, and gradually increased from the minimum quantity until its characteristic effects begin to be manifested. The pilular form is the best adapted for its administration.

NYMPHÆA.—WATER-LILY.

Pond-lily, E.; *Nénuphar*, *Lune d'eau*, Fr.; *Seerose*, *Wasserlilie*, G.

Nat Ord.—Nymphæaceæ.

Description.—The following species, of which two belong to North America, have been employed.

NYMPHÆA ODORATA, *Ait.* *Sweet scented water-lily.*—It has a horizontal immersed rhizome, which is 2 or 3 inches thick, verrucose and brown externally, yellowish-white internally, fleshy, after drying deeply wrinkled, spongy and light. It is without odor, and has a bitter mucilaginous, somewhat astringent taste. The leaves are large orbicular-cordate and entire; the flowers are 4 or 5 inches broad, many-petalous, white, and very fragrant.

NYMPHÆA ALBA, *Lin.*—The European water-lily resembles the preceding, the chief differences being found in the shape of the fruit and the greater number of its stigmas.

NUPHAR ADVENA, *Ait.* (Nymphæa, *Mich.*) *Yellow pond-lily*, *Spatter-dock.*—The rhizome resembles the above, and is nearly of the same dimensions. The leaves are heart-shaped at the base, with rather divergent lobes, and vary between ovate and roundish in outline. The flowers have 6 yellow sepals, and numerous small yellow petals, which resemble the stamens.

Constituents.—The rhizome of Nymphæa alba was examined by Morin (1819), and Carminati, and that of N. odorata by Bigelow. Tannin, mucilage, etc., were found, but the bitter principle has not been isolated.

Medical Action and Uses.—The root of our native pond-lily is astringent and demulcent, and is used internally for the cure of *bowel complaints*, and topically in cataplasm for ulcers, and in decoction for *leucorrhœa* and *dysentery.* The European species, N. alba, was once reputed to be anaphrodisiac, and the juice of the fresh root is said to be acrid, and even capable of reddening the skin. An ointment is prepared with it to stimulate the scalp when the hair tends to fall out.

ŒNOTHERA.—EVENING PRIMROSE.

Onagre, Fr.; *Nachtkerze*, G.

Œnothera biennis, *Lin.* *Nat. Ord.*—Onagraceæ.

Description.—This very variable plant is common throughout North America, in fields and waste places, and has been naturalized in Europe. It has a conical *root*, which is ½ to 1 inch thick at the base, 4 to 6 inches long, with spreading branches, externally pale brown or sometimes reddish, with a thin bark, internally white, fleshy, inodorous, of a sweetish taste, and in the second year woody and tough. The *stem* is from 3 to 6 inches high, rough, hairy, often purplish. The *leaves* are ovate-oblong or oblong-lanceolate, 3 to 5 inches long, somewhat petiolate, acute, nearly entire, and short-hairy. The *flowers* are in terminal leafy spikes, have a sessile cylindrical ovary united with the long tubular calyx, 4 obcordate yellow petals, and 8 stamens, and produce a four-valved capsule, containing numerous seeds. The herb is inodorous, and has a mucilaginous and mild astringent taste. The root and the flowering plant are used.

Constituents.—Diot Chicoisneau (1834) found the plant to contain much mucilage; his *œnotherin* was a mixture of several bodies, which have not been separated from one another.

Medical Action and Uses.—The late Dr. R. E. Griffith, in his Medical Botany, after speaking of the mucilaginous and acrid qualities of the herbs and leaves, states that he made use of it in several cases of infantile eruptions which had resisted other modes of treatment, and became satisfied that it was highly beneficial, a judgment which his subsequent experience confirmed. It is advised that about the flowering season, the small twigs with the bark of the large branches and stem, retaining their leaves, should be dried in the shade. Of these a strong decoction is made, with which the eruptions should be bathed several times a day. We are not acquainted with any later and confirmatory reports upon this plant. It has also been used in *diarrhœa* and in *asthma*.

OLEA DESTILLATA.—VOLATILE OILS.

Olea ætherea s. volatilia, Ætherolea.—Essential (ethereal or distilled) oils, E.; *Huiles volatiles (éthérées, essentielles, distillées), Essences*, Fr.; *Flüchtige (Ætherische) Oele*, G.

Characters.—Volatile oils are those proximate principles to which in the majority of cases the odor of plants is due. They have no chemical, and but few physical, properties in common with the fixed oils, but, like the latter, they are generally soluble in ether, chloroform, bisulphide of carbon, etc., and, when dropped upon paper, leave a stain resembling that produced by fat, but which, unlike the latter, disappears upon the application of heat. Their specific gravity usually ranges between 0.85 and 0.99; a few are still lighter, and some are heavier than water, one reaching the specific gravity 1.17. All are inflammable, and burn with a bright but very sooty flame. They possess the odor of the plants from which they have been obtained, but are usually less fragrant, which is probably due to the presence in the plants of other odoriferous compounds, perhaps compound ethers, which, being more soluble in water, are removed during the distillation; it is on this account that medicated waters distilled from the drug, almost without exception, possess a more agreeable odor and taste than when prepared from the volatile oil.

When exposed to the air, volatile oils become ozonized, and are more or less rapidly converted into a viscid oil or even solid resin; to the presence of ozone is due their bleaching effect upon corks, indigo solution, etc. (See a paper by Dr. J. L. Plummer in *Amer. Journ. Pharm.*, 1853, p. 398 and 508; also, 1860, p. 46.)

Origin.—Volatile oils are met with in a large number of plants, and may exist in every part thereof, from the root to the seed. If found in several parts of the same plant, the volatile oils obtained from them generally differ more or less, not only in odor and other physical properties, but frequently also in chemical composition. They are often separated in the plant in distinct cells, appearing as glands in the herbaceous portion, or distributed throughout the interior tissue, or forming tubes as in the fruits of the Umbelliferæ. Very frequently they are associated with resins, and even exude, either naturally or from incisions, holding resins in solution (oleoresins and many gum resins). In a number of plants they are known to be produced under the action of a ferment, like emulsin and myrosin, upon other compounds, such as amygdalin and myronic acid; but in most cases it has been impossible to demonstrate either the precise tissue where they are produced, or the compounds which yield them. There is, however, reason to believe that, at least in some cases, they result from the splitting of glucosides, resins, and similar principles. All volatile oils yield by spontaneous oxidation resinous compounds, which, however, have thus far been found to be entirely distinct from the resins with which the former have been naturally associated.

Among the products of the destructive distillation of organic bodies, compounds are often found which possess the general characters of volatile oils, but usually have an empyreumatic odor persistently adhering to them; they are called *empyreumatic volatile oils.* Odorous compounds, sometimes known as *ferment oils* (*fermentolea*), are also produced during the fermentation of bruised vegetables or their expressed juice; they are probably alcohols or compound ethers.

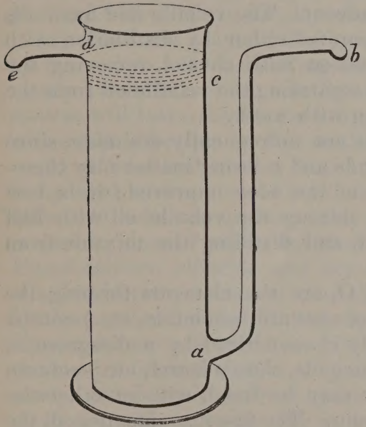
Preparation.—In a few instances, where the volatile oils are separated in cells of the epidermal tissue and not associated with resinous or fatty matters, as in the fruits of many Aurantiaceæ, they may be prepared by expressing that tissue after removing it by grating. By far the largest number, however, require to be distilled with water. Herbaceous plants, flowers, and leaves which are not of a leathery nature usually need no previous comminution; but firmer parts of plants, and those containing the volatile oil in the inner tissues, must be more or less ground or broken. Though fresh plants are usually readily softened and permeated by water, a short maceration before the distillation begins is rather advantageous, and may be regarded as very desirable if dried plants are employed; it is unnecessary in case the volatile oils are to be distilled off from resinous compounds, but whenever the volatile oil does not pre-exist, but is produced by the reaction of two principles in the presence of water, a prolonged maceration in cool or lukewarm water is required.

The *distillation* is accomplished in stills made of copper or iron, a sufficient quantity of water being introduced to cover the material and prevent empyreuma; the latter object is more completely attained if a perforated false bottom is placed a few inches above the bottom of the still and the material packed upon it. Direct heat is then applied until the water boils briskly, and is maintained at this temperature until the distillate is no longer charged with volatile oil. Some volatile oils are obtained of better quality and greater fragrance if the direct application of fire to the still is avoided and the volatilization is accomplished by the introduction, near the bottom, of steam under pressure; a wooden tank may then be converted into a still by cutting a suitable aperture into the top and surmounting it with a still-head. Steam distillation is particularly applicable for flowers like those of the orange, lavender, chamomile, etc., and for the labiate and other herbs.

Although volatile oils have a higher boiling point than water, the majority boiling above 140° C. (284° F.), their vapors diffuse readily in the vapors of water at the boiling temperature of the latter, and are thus easily carried over. Greater difficulty, however, is experienced with those volatile oils which have either an exceptionally high boiling point or a specific gravity near or exceeding that of water; the addition to the water of about 3 per cent. of table salt is then advisable, whereby the boiling point is somewhat raised, and, as the water distils over, it may be gradually increased to about 109.5° C. (229° F.). The volatile oils of cloves, cinnamon, santal wood, etc. are thus more readily obtained than with water alone.

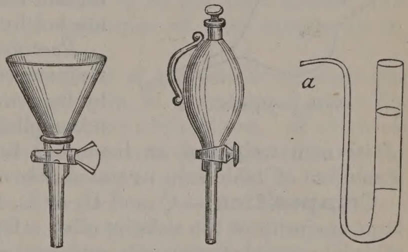
Cohobation is the returning of the aqueous distillate from which the volatile oil has been separated, either upon the same or upon fresh portions of material, and distilling again. The process is rendered necessary with cloves, santal wood, etc., the firm tissue of which containing the volatile oils is not easily ruptured or thoroughly permeated by water, and with the petals of rose and similar articles which contain only a minute proportion of volatile oil.

Fig. 116.



Separator for Heavy or Light Oils.

Fig. 117.



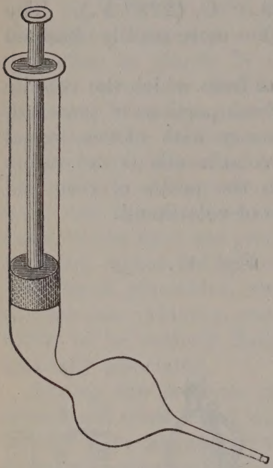
Separating Funnels and Tube-separator.

Separation.—On cooling, the distillate separates into two layers, one being a solution of the volatile oil in water, the other the pure oil. A tall cylinder or flask is used, which, near the bottom, has a glass or other tube inserted and curved upward to a short distance below the top. The heavier water separating at the bottom will commence to discharge through the lateral tube *b*, as soon as the vessel is nearly filled with the distillate, upon which will float a layer of volatile oil; this layer may be withdrawn by means of a small siphon, or, better still, through a lateral tube *e*, inserted near the top of the vessel. If the volatile oil, however, is heavier than water, the conditions will be reversed, and the oil will flow through *a* and run off at *b*. The last portions of volatile oil are removed from the water by means of a separating funnel (Fig. 117), the separation being effected with a perforated glass stopper inserted in the neck or by inclining the vessel (Fig. 117) through the tube *a*. For very small quantities a bulb-pipette will be found useful, the longer tube of which is drawn out to a fine point. By a suitable arrangement, the separated odorous water may be returned to the still while the distillation is progressing.

If volatile oils are present only in minute quantities, frequent cohobation is required, but even then too much is often lost by being retained in the water, as in the case of violets, tuberoses, etc. To obtain these delicate perfumes, Millon and Commaille (1868) employed purified bisulphide of carbon, with which the material is exhausted, and on the spontaneous evaporation of which all the odoriferous compounds are left behind.

The process of *enfleurage* is likewise adapted for obtaining delicate perfumes. A number of trays or frames are covered with a layer of purified tallow or other inodorous fat, and then with flowers, the latter, if necessary, being replaced by fresh flowers in a few days. When the fat is sufficiently charged with the perfume, it constitutes the *pommades* used by perfumers, from which the *extracts* are obtained by digestion with pure alcohol; the small *portion of fat* entering solution separates on exposure to a low temperature.

Fig. 118.



Syringe-pipette.

L. Wolff (1877) proposed a process for preparing volatile oils whereby distillation may either be entirely avoided or materially shortened. Petroleum benzin dissolves from plants chiefly the volatile and fixed oils and wax which are left after evaporating the solvent. The volatile and fixed oils may then be separated either by distillation with water, or by agitation with alcohol, removing the fat and wax, and separating the volatile oil from the alcohol by mixing with water.

Rectification is not unfrequently desirable, since resinous compounds and coloring matter may thereby be removed and the odor improved; it is best accomplished by mixing the volatile oil with half of its own weight of an inodorous liquid fat, and distilling the mixture from a solution of table salt, as stated above.

Composition.—C and H, or C, H, and O, are the elements forming the large majority of the volatile oils; a few (oil of mustard, asafœtida, etc.) consist of sulphuretted compounds, and are generally characterized by a disagreeable penetrating odor; some others (oil of bitter almonds, cherry laurel, etc.) contain hydrocyanic acid, from which, however, they may be freed, without otherwise altering their composition or modifying their odor. The first class mentioned, the hydrocarbons, are mostly *terpenes*, consisting of two or more isomeric modifications, having the composition $C_{10}H_{16}$, or a multiple thereof. The oxygenated volatile oils likewise consist proximately of at least two principles, boiling at different temperatures. The one having the lowest boiling point is called *elæopten*, and very often is a hydrocarbon of the composition $C_{10}H_{16}$ or $C_{10}H_{14}$. *Stearopten* is that portion which volatilizes last and congeals at about the ordinary temperature; in composition it is not unfrequently an oxide or hydrate of the hydrocarbon. The stearopten of oil of rose is a hydrocarbon C_nH_{2n}, and has a lower boiling point than the fragrant oxygenated portion. Stearoptens, or *camphors*, as they are sometimes called, crystallize from the volatile oils on exposure to a low temperature, the crystallizing point depending partly on the fusing point of the stearopten, and partly on the amount of the solvent elæopten. The variation in the proportion of the two proximate constituents is due to the influence of climate, soil, and cultivation, and modifies to some extent the effect upon polarized light.

The *color* of volatile oils appears to be due to distinct compounds. Piesse (1863) separated from oil of wormwood, patchouly, etc., a volatile dark-blue body, *azulene* (according to Gladstone [1863] *cærulein*) of the composition $C_{16}H_{26}O$, which he stated to be present in all blue-colored volatile oils, while those having a different color are free from it or contain it in smaller proportion mixed with more or less of yellow or brown resin.

Preservation.—Since volatile oils oxidize when in contact with air, and the oxidation is accelerated in the light, they should be kept in well-stoppered vessels protected against the light. Various contrivances, which readily suggest themselves, have been recommended. Bottles of amber-colored glass, which excludes the actinic rays, are very suitable; and the addition of a small quantity of alcohol, which in our experience need not exceed three per cent., will prevent for a long time, if not the oxidation, at least the marked change of odor which oils of orange, lemon, peppermint, and others undergo. Menigaut, as early as 1835, proposed for the same purpose the addition of an equal weight of alcohol.

Restoration.—Resinified volatile oils, the flavor of which has not been impaired, may be restored to their former limpidity by rectification (see above). Small quantities of such volatile oils Curieux (1858) recommended to be agitated for fifteen or twenty minutes with a magma formed by mixing solution of borax with animal charcoal, when the resinified portion will unite with the borax, leaving the oil limpid and the odor restored.

Adulterations.—Among the numerous methods which have been recommended for detecting the principal adulterations to which volatile oils are subject, the following are simple, reliable, and easily executed:—

(a) *Fixed oils* are indicated by the permanent greasy stain left upon paper, or by the residue left on distilling the suspected oil with water. Since the fats are mostly insoluble and the volatile oils mostly soluble in 85 per cent. alcohol, this solvent will leave the former behind; minute quantities of fixed oils, however, will escape detection by this method.

(b) *Alcohol* will cause a diminution of the volume of the volatile oil when this is agitated with an equal bulk of water or glycerin in a graduated tube; the difference indicates approximately the amount of the adulteration. If olive oil is used in place of water, the alcohol, unless in very small quantity, will separate. Fused calcium chloride and dry acetate of potassium are insoluble in volatile oils, but in the presence of alcohol become either soft or liquid. Tannin, which has been recommended for the same purpose, is soluble in oil of bitter almonds, cinnamon, and a few others. Dragendorff recommends metallic sodium, which produces a brisk evolution of gas in the presence of even 5 or 10 per cent. of alcohol, while hydrocarbons are not at all, and oxygenated oils but slightly acted on in the cold. Anilin red is soluble in alcohol and insoluble in volatile oils; but if the oils contain alcohol they are colored red by the dry anilin color.

(c) *Cheap volatile oils* are often difficult to detect. On rubbing a few drops of the volatile oil between the hands, or heating them gradually in a dish, or evaporating them from bibulous paper, and observing the odor from time to time, a marked difference of it is indicative of such adulteration. The hydrocarbons being mostly cheaper and less freely soluble in 85 per cent. alcohol than the oxygenated oils, an adulteration with the former will generally be recognized by the solvent mentioned.

The solubility of santal red in some volatile oils (Voget), the different reaction of these oils with iodine (Tuchen), the change of color produced on heating oxygenated volatile oils with a little nitroprusside of copper, and the prevention of this reaction by oil of turpentine and other hydrocarbons (Heppe, 1856), and the behavior of the volatile oils towards strong mineral acids, potassa, bromine, sulphide of lead, and other chemicals, may, at least occasionally, be utilized for the purpose of detecting adulterations. (See *Proceedings Amer. Pharm. Assoc.*, 1858, p. 344, and 1859, p. 338.)

OLEA PINGUIA.—Fixed Oils.

Fats, E.; *Huiles grasses*, *Huiles fixes*, Fr.; *Fette*, *Fette Œle*, G.

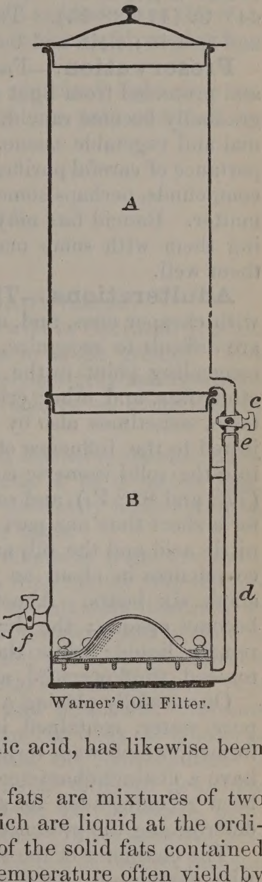
Characters.—Fats are peculiar compounds obtained both from the animal and the vegetable kingdom. In their pure state they are often colorless, inodorous, and tasteless. Many are liquid at the ordinary temperature (*oils* or *fixed oils* proper), but by cautious cooling may generally be separated into fats of different fusibility. Others have a soft consistence (*fats* proper, or *butters*), and mostly yield liquid fats when subjected to a gradually increased pressure, while a fat of a higher fusing point remains in the press-cloth. Those of a firmer consistence are sometimes termed *tallows;* and when hard, and more or less brittle at the common temperature, they are often popularly and commercially known as *waxes.* They are all lighter than water, and vary in specific gravity generally between .913 and .956, though some are as light as .860. They are insoluble in water, sparingly soluble in cold alcohol, but generally freely soluble in ether, chloroform, carbon bisulphide, benzol, and light petroleum oils. The hot alcoholic solution of the solid fats separates them on cooling generally in a crystalline form. When heated, the solid fats fuse to transparent oils and solidify again on cooling. Heintz observed that by raising the heat very slowly, some fats show two fusing points, which for pure stearin were found at 55° C. (131° F.) and 71.6° C. (160.9° F.), and also two congealing points, the latter depending upon the temperature to which the fat had been heated and upon the rapidity with which it had cooled. After having been heated considerably beyond the fusing point some solid fats remain liquid for a long time after cooling; at a higher temperature, usually in the neighborhood of 300° C. (572° F.), an ebullition is observed, accompanied by decomposition, the boiling point gradually rises, and extremely acrid and irritating vapors are evolved, causing a copious flow of tears, and containing *acrolein.* (See Glycerin, p. 671.)

Fats are more or less unctuous to the touch, and when in a liquid condition dropped upon paper leave a permanent grease spot, unless they are crystalline and so hard that they may be rubbed off. They are not inflammable at the ordinary temperature, but when heated to incipient decomposition, burn more or less readily by the aid of wick and with a sooty flame. When their surface is considerably increased by being spread over porous bodies, they are rapidly oxidized, whereby the heat may be increased to such an extent as to ignite the entire mass.

Origin.—All plants, and perhaps all parts of plants, contain fat, though often in minute quantity. The liquid and solid fats are most likely generated from starch and other carbohydrates and allied compounds; De Luca (1862) proved that the fixed oil of olives increases in quantity as the mannite of the green olives disappears, and that the access of air and light facilitates the conversion. It is not unlikely that certain protein compounds may likewise be the source of fats. In the animal economy fats are, at least partly, produced in a similar manner.

Preparation.—From animal tissues rich in fat, the latter is obtained by fusion either by itself or in the presence of water, and removal of the tissue by skimming or straining. Vegetable tissues containing notable quantities of fat yield it on being subjected to powerful pressure, either at the ordinary temperature or between plates which are heated to a little beyond the fusing point of the fat; but since a certain quantity of the fat is mechanically retained by the tissues, a larger yield is had by the use of a solvent, such as carbon bisulphide or petroleum benzin, which, on being distilled off, leaves the fat behind. When the bruised or cut vegetables are boiled with water, the fused fat rises to the surface, and may either be skimmed off, or obtained by straining, expression, and subsequent separation from the water; such fats are usually inferior to those obtained from the dried article by pressure alone.

Fig. 119.



Warner's Oil Filter.

Purification.—The impurities contained in fats are protein and mucilaginous compounds derived from the vegetable tissue, and may be removed through a well-dried filter; the filtration is facilitated by a somewhat elevated temperature. An apparatus suitable for this purpose, and for filtering through flannel in an upward direction and under pressure of a column of the oil, was constructed by W. R. Warner (1861); A, is the reservoir containing the oil; B, the recipient of the filtered oil. On the large scale the purification is effected by the gradual addition to the oil of about 2 per cent. of sulphuric acid, whereby the impurities are carbonized; the oil is then agitated with water to remove adhering acid, decanted and often filtered through charcoal. Barreswil (1858) recommended for the same purpose the saponification of a small proportion of the fat by means of a weak alkali. The loss sustained in purification varies with the nature and amount of the impurities, and in some cases reaches 15 or 20 per cent. of the crude oil.

Bleaching.—The treatment of fats with sulphuric acid usually destroys also the coloring matter wholly or in part; treatment with animal charcoal renders the fats lighter, and many are bleached (and often become rancid) by exposure to the direct sunlight, a strip of lead being sometimes introduced into the fat if liquid, or this is occasionally agitated with an aqueous solution of ferrous sulphate. Palm oil is bleached by being rapidly heated to 240° C. (464° F.), and keeping it at this temperature for ten minutes. The same effect is produced upon oil of poppy-seed by heating it for five hours to between 90° and 95° C. (194° and 203° F.). Oxidation of the coloring principle, by means of permanganic or chromic acid, has likewise been recommended.

Composition.—Nearly all animal and vegetable fats are mixtures of two or more fats having a different fusing point; those which are liquid at the ordidary temperature separate in the cold granular masses of the solid fats contained in them; while those which are solid at the common temperature often yield by expression a liquid oil. With comparatively few exceptions, fats are compound ethers of the triatomic alcohol glycerin (see page 671), and the acids contained in them belong to two series, the fatty acid group of the general formula $C_nH_{2n}O_2$ and the oleic acid group of the formula $C_nH_{2n-2}O_2$. The most important members of the first group are stearic ($C_{18}H_{36}O_2$), palmitic ($C_{16}H_{32}O_2$), myristic ($C_{14}H_{28}O_2$), lauric ($C_{12}H_{24}O_2$), and butyric ($C_4H_8O_2$) acids. To the second group belong, besides oleic acid ($C_{18}H_{34}O_2$), erucic ($C_{22}H_{42}O_2$) and hypogæic ($C_{16}H_{30}O_2$) acids; the former being found in oil of mustard, the latter in oil of groundnut. All these acids are monobasic, and the neutral fats therefore contain three molecules of the acid to one of the ether, $C_3H_5O_3$, which is sometimes called *oxide of glyceryl* or *of lipyl;* these compounds are conveniently named from the acid by changing the termination to *in;* thus *stearin* or *tristearin* is $C_3H_5O_3.3C_{18}H_{36}O_2$, and *olein* or *triolein* has the formula $C_3H_5O_3.3C_{18}H_{34}O_2$. The fats most widely distributed are olein, stearin, palmitin, myristin, and laurin, which are inodorous when pure, while the fats of the volatile acids have a distinct odor, the most important being *butyrin.* Fats which, on exposure to air, gradually solidify through the absorption of oxygen, the so-called *drying oils*, are supposed to contain *olin*, the composition of which is not known; the drying fat of linseed oil has been named *linolein.*

The fusing points of the above-named pure fats are as follows: Stearin 55° C. (131° F.), palmitin 48° C. (118.4° F.), myristin 31° C. (87.8° F.), laurin 44° C. (111.2° F.). The margarin of older chemists is a mixture of palmitin and stearin; olein and butyrin are liquid at common temperatures.

Preservation.—Fats should be kept in a dry place, at a low temperature, and protected from light and air. On being exposed to the atmosphere the fats gradually become rancid, and this change is accelerated by the presence of animal and vegetable tissue, protein and mucilaginous compounds; hence the importance of careful purification. The rancidity is due to the generation of odorous compounds, perhaps some acrolein and volatile fatty acids, besides some coloring matter. Rancid fats may be restored by washing with warm water, or by treating them with some magnesia or other weak alkali, and afterwards washing them well.

Adulterations.—The higher priced fats are not unfrequently adulterated with cheaper ones, and, owing to the similarity of composition, such admixtures are difficult to recognize. A change of the fusing point in the solid and of the congealing point in the liquid fats is not unfrequently produced by addition of other fats, and other criteria are afforded by the color, consistence, odor, and taste, sometimes also by the specific gravity. The non-drying oils when subjected to the influence of nitrous acid become solid, the olein being converted into the solid isomeric compound *elaidin*, which fuses between 25° and 28° C. (77° and 82° F.), and solidifies again on cooling. The test is made by agitating for a short time one part of copper in small pieces with about five parts each of nitric acid and the oil, and setting the mixture aside; the separation of elaidin commences in about an hour, and the solidification is generally completed in about six hours. Almond oil and olive oil are scarcely colored thereby, but become opaque; the drying oils (linseed, poppyseed, hempseed and nut-oils) remain liquid; while the following become thicker, but not solid: Castor, cottonseed, sunflowerseed, and benneseed-oil, the latter acquiring also a red color.

On carefully placing a drop of oil or oleoresin upon the surface of chemically pure water, contained in a perfectly clean glass vessel, distinct figures are formed, which were termed *cohesion figures* by C. Tomlinson (1864), and which have a distinct character for the different liquids. These cohesion figures have been recommended as a means of identifying the liquids and possibly also of determining the presence of admixtures.

The character of the soda soap may likewise serve to indicate an adulteration with drying oils; for this purpose the oil is agitated with one-third of its weight or more of soda solution, specific gravity 1.33 (containing 30 per cent. NaHO), and the mixture boiled until saponification has been effected; after cooling, the soap of the drying oils will be soft, and should oils of cruciferæ (mustard, etc.) have been present, the aqueous filtrate will impart a black color to paper moistened with solution of lead acetate, owing to the sulphur present in the oil.

Concentrated sulphuric acid produces with different fixed oils mixtures varying in color; 8 or 10 drops of the oil are placed upon a china plate, 3 drops of sulphuric acid are added, and after a few seconds mixed by stirring; the color of the mixture will be as follows: with *almond oil* yellow changing to pale brownish-yellow; with *olive oil* yellow turning brown; with *benne oil* brown-red becoming gelatinous; with *linseed oil* brown-red to blackish-brown; with *rapeseed oil* greenish-blue or brownish-green; with *poppy-seed oil* yellow to brownish-green; with *castor oil* brownish to gray-brown. When larger quantities of oil are mixed with sulphuric acid, a rise of temperature takes place, which is not alike for different oils. According to Behrens (1852) when a cold mixture of equal parts of nitric and sulphuric acid is added to an equal weight of oil, *benne oil* acquires a green, *ground-nut oil* a red, and *olive oil* a yellow color. (See also Ol. amygdal. express.)

Lipowitz (1868) observed that the admixture of drying in non-drying oils may be detected, by triturating 8 parts of the oil with 1 part of chlorinated lime; in the course of a few hours the mixture, if made with non-drying oils, will separate a layer of limpid oil, while no oily layer will separate from the mixture containing a drying oil. This appears to be due to the rapid oxidation of the latter.

Since most of the fats are without action upon it, polarized light does not afford a means of distinguishing them; of the officinal oils, only castor oil has a decided rotation to the right.

OLEANDER.—OLEANDER.

Laurier rose, Laurose, Fr.; *Oleander*, G.

The leaves of Nerium oleander, *Lin.* *Nat. Ord.*—Apocynaceæ.

Origin.—This well-known ornamental shrub grows wild in Southern Europe, Northern Africa, and Western Asia, and thrives best in moist ground. It is 10 to 15 feet high, often arborescent, with a gray or greenish-gray nearly smooth bark, ternately divided branches and showy dark-rose colored or white flowers. All parts are reputed to possess poisonous properties.

Description.—The leaves are whorled in threes, leathery, smooth, dark-green and glossy above, nearly sessile, linear-lanceolate, 4 to 6 inches long, finely pointed at the apex, entire on the margin, and delicately feather-veined. They are without odor, and have a nauseous and bitter taste.

Constituents.—Lukomski (1861) obtained two alkaloids from the leaves and branches by carefully precipitating their decoction with tannin; the tannate of pseudocuraria is soluble in an excess of tannin and the alkaloid liberated by oxide of lead. *Pseudocuraria* is amorphous, yellowish, tasteless, and inodorous, insoluble in ether, freely soluble in water and alcohol, and yields uncrystallizable salts. *Oleandria* is a yellowish resinous body, slightly soluble in water, very soluble in alcohol and ether, of a strongly bitter taste and poisonous. Its salts are uncrystallizable. Bitteli (1875) observed that oleandria loses its poisonous properties when heated to 240° C. (464° F.), and that the hydrochlorate is crystalline; he regards the pseudocuraria as a mixture of different principles containing a little oleandria. Pelikan (1866) considered the poisonous principle to be a yellow acrid resin, which according to Latour (1857) possesses acid properties. The latter chemist determined also the presence of tannin, fat, and other common principles.

Medical Action and Uses.—This is one of the plants whose flowers are said to render honey poisonous; and the experiments of Pelikan seem to show that its active principle is a heart poison. It has been used in epilepsy, but fruitlessly.

OLEATA.—OLEATES.

Oléates, Fr.; *Oleate*, G.

This class of preparations was introduced by Professor John Marshall (1872). They are made from oleic acid, by combining with it metallic bases and alkaloids, nearly all of which dissolve easily in the acid on trituration in a mortar. The application of heat should be avoided, since oleic acid is very readily altered by it, and some of the metallic oxides are reduced.

Oleic acid is obtained as a secondary product at the stearin candle factories, and may be prepared, according to Bromeis (1842), by saponifying almond or olive oil with potassa, decomposing the soap with hydrochloric acid, combining the fatty acids with lead, by digesting with oxide of lead, dissolving the oleate of lead in ether, and agitating the ethereal solution with hydrochloric acid. On evaporating the ether, oleic acid remains behind, which requires to be washed with water. In its pure state it is a colorless oily liquid, which congeals to a white crystalline mass at 4° C. (39.2° F.), and fuses again at 14° C. (57.2° F.). When heated to a little above the boiling point of water, it rapidly acquires a dark brown color. Its composition is $C_{18}H_{34}O_2$. As found in commerce, oleic acid is of a yellow color. Should it contain notable quantities of the solid fatty acids, it may be deprived of the greater part of them, according to Ch. Rice (1873), by exposing it to a temperature of 4.5° C. (40° F.), and expressing the liquid portion.

Oleate of mercury has been used containing different amounts of mercury the most serviceable of which seems to be that containing 20 per cent. of the oxide. One part of dry precipitated oxide of mercury is triturated at a slightly elevated temperature with four parts of oleic acid. It is of a soft solid consistence, and may be readily reduced to any desired strength by the addition of the requisite amount of oleic acid.

Oleate of lead, containing 20 per cent. of oxide of lead, is a tenacious mass.

Oleate of zinc, of the same strength, according to A. W. Gerrard (1872), is hard and friable, but transparent when melted.

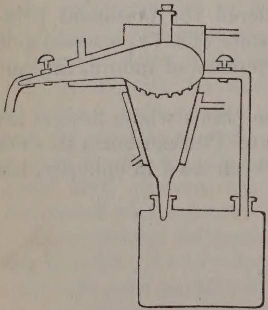
The *Oleates of morphia*, *atropia*, *aconitia*, and other alkaloids are made by dissolving two grains of the alkaloid in 98 grains of oleic acid. The preparation will then contain 2 per cent. of the alkaloid.

OLEORESINÆ.—Oleoresins.

Oléo-résines, *Extraits éthérés*, Fr.; *Œlharze*, *Ætherische Extracte*, G.

These preparations consist mainly of fixed or volatile oils associated with resin and some other constituents, and are directed to be prepared by exhausting the powdered drug with ether. The great volatility of this solvent renders it necessary to percolate in a well-closed apparatus, in which the pressure is equalized by connecting the receiving vessel with the top of the percolator by means of a tube (see page 589). The ethereal tincture is afterwards transferred to a suitable still, and the ether distilled off with a moderate heat. Various apparatuses have been constructed to accomplish the exhaustion with the smallest possible quantity of ether, by using the same liquid over again until the material has been exhausted; for this purpose the recipient is placed in hot water, the ether vapors ascending through the connecting tube mentioned above are condensed in a suitable refrigerator, and the ether is again passed into the percolator, the operation being repeated as often as required. The annexed cut, taken from Parrish's Pharmacy, represents such an apparatus, which is best made of tinned sheet-iron, or preferably of copper well tinned on the inside; it explains itself, and it is merely necessary to state that the head is perforated at the bottom for the equal distribution of

Fig. 120.



Percolator with still and condenser for preparing oleoresins.

the menstruum, and jacketed above for the condensation of the ether. The percolator being likewise jacketed, it may be immersed in hot water, and the ether recovered, which remains in the powder after the exhaustion of the powder.

If the operation has been carefully conducted, the ether thus regained is not at all or but very slightly impregnated with volatile oil; nevertheless, it must be regarded as unfit for internal use, and should be reserved for a similar subsequent operation.

OLEORESINA CAPSICI, *U. S.*—Oleoresin of Capsicum.

Oléorésine (Extrait éthérée) de capsique, Fr.; *Spanischpfeffer-Oelharz*, G.

Preparation.—Take of Capsicum in fine powder twelve troyounces; Ether a sufficient quantity. Put the capsicum into a cylindrical percolator, provided with a cork, and arranged with cover and receptacle suitable for volatile liquids, press it firmly, and gradually pour ether upon it, until twenty-four fluidounces of liquid have slowly passed. Recover the greater part of the ether, by distillation on a water-bath, and expose the residue in a capsule until the remaining ether has evaporated. Lastly, remove, by straining, the fatty matter which separates on standing, and keep the oleoresin in a well-stopped bottle. *U. S.*

It is a dark brown-red rather thick liquid, separating on standing a granular deposit of fat, which mechanically incloses a portion of the oleoresin, that may be recovered by washing several times with small quantities of ether. Instead of removing the fat by straining, we prefer to decant the clear oleoresin, and treat the remainder as stated. The yield is about 4 per cent. The oleoresin has but little odor, but possesses an extremely hot and fiery taste.

Medical Uses.—This preparation appears to be nearly superfluous as an internal medicine, since all the virtues it can exert in that manner are sufficiently exhibited by capsicum. It is occasionally added to liniments to increase their rubefacient action, but is more beneficially incorporated in plasters, such as soap or lead plaster, for a similar purpose.

OLEORESINA CUBEBÆ, *U. S.*—Oleoresin of Cubeb.

Extractum cubebarum, P. G.; *Extractum cubebæ æthereum.*—*Oléorésine de cubébe*, Fr.; *Kubebenextrakt*, G.

Preparation.—Take of Cubeb in fine powder twelve troyounces; Ether a sufficient quantity. Put the cubeb into a cylindrical percolator, provided with a cork and arranged with cover and receptacle suitable for volatile liquids, press it moderately, and gradually pour ether upon it until twenty-four fluidounces of liquid have slowly passed. Recover the greater part of the ether by distillation on a water-bath, and expose the residue, in a capsule, until the remaining ether has evaporated. When, after standing in a close vessel, waxy and crystalline matter has been deposited, decant the oleoresin and keep it in a well-stopped bottle. *U. S.*

The German Pharmacopœia has a similar preparation, made, however, by extracting the cubebs with a mixture of equal weights of ether and alcohol; it probably contains less volatile oil, a portion of which must volatilize with the last portions of alcohol. The oleoresin, as prepared by the above formula, is of a brown-green, or sometimes of a grass-green color, the difference being due to the presence of more or less chlorophyll. On standing, it deposits some waxy matter and cubebin, which are removed by decantation. The remaining liquid, amounting to between 20 and 25 per cent. of the cubebs used, consists mainly of fixed and volatile oils, the active resins, and chlorophyll. An alcoholic ether dissolves more brown coloring matter.

Off. Prep.—Trochischi cubebæ, *U. S.*

Medical Uses.—Investigations for the purpose of discovering upon which of the constituents of cubeb its medicinal value depends, have not reached a perfectly definite conclusion; but it may be considered that its most active element is cubebic acid, which, when taken in doses of from seventy to ninety grains, produces a lively sensation of heat in the stomach, increases the urine, and renders it hot and irritating. In the dose of 150 grains, it occasions also eructation, flatulence, a pervading sense of warmth, and some quickening of the pulse. The *dose* of the oleoresin is stated to be from five to thirty minims, which may be given on sugar, or preferably inclosed in gelatin capsules.

OLEORESINA FILICIS, *U. S.*—OLEORESIN OF MALE FERN.

Extractum filicis æthereum, Br.; *Extractum filicis*, P. G.; *Oleum filicis maris.*—*Liquid extract of male fern*, E.; *Huile* (*Extrait éthéré*) *de fougère mâle*, Fr.; *Wurmfarnextrakt*, *Wurmfarnöl*, G.

Preparation.—Take of Male Fern in fine powder twelve troyounces; Ether a sufficient quantity. Put the male fern into a cylindrical glass percolator, provided with a cork and arranged with cover and receptacle suitable for volatile liquids, press it firmly, and gradually pour ether upon it until twenty-four fluidounces of liquid have slowly passed. Recover the greater part of the ether, by distillation on a water-bath, and expose the residue in a capsule until the remaining ether has evaporated. Lastly, keep the oleoresin in a well-stopped bottle. *U. S.*

The processes of the British and German Pharmacopœias are essentially identical with the above, except that the latter directs maceration instead of percolation. It should be remembered that only that portion of the rhizome is to be used which has still a greenish color; the oleoresin will then have a greenish or brownish-green color, while the entire rhizome with the stipes yields a brown preparation, which not unfrequently forms a jelly, probably from the separation of pectin compounds. The officinal oleoresin separates a granular depositof filicic acid, which must be well mixed with the liquid portion on dispensing. The yield is about 10 or 12 per cent.

Medical Action and Uses.—Since the introduction into practice of this preparation, whose activity depends upon the filicic acid it contains, the treatment of *tænia* has been rendered prompt and certain, at least so far as relates to the armed tænia and bothriocephalus. It appears to act as a poison to the parasites, which are discharged dead. The medicine may occasion nausea, griping, and even vomiting, but usually without either pain or uneasiness. It is well to prepare the patient by administering a purgative dose of castor oil or of calomel a day before the oleoresin, and to restrict his diet to milk and light broths. The oleoresin is best prescribed in capsules each containing six or seven grains. Some advise that an equal quantity of ether should be contained in every one. Of these capsules two should be taken every fifteen minutes until one and a half or two fluidrachms of the oleoresin shall have been used. In the course of two or three hours, purging begins, and after several stools the worm is generally expelled, dead. It has been suggested that the patient should evacuate the bowel in a vessel nearly full of water, so that the parasite need not break, and that its parts may be readily distinguished.

OLEORESINA LUPULINÆ, *U. S.*—OLEORESIN OF LUPULIN.

Extractum lupulini æthereum.—Oléorésine de lupuline, Fr.; *Ätherisches Lupulinextrakt*, G.

Preparation.—Take of Lupulin twelve troyounces; Ether a sufficient quantity. Put the lupulin into a narrow cylindrical percolator, provided with a cork and arranged with cover and receptacle suitable for volatile liquids, press it firmly, and gradually pour ether upon it, until twenty fluidounces of liquid have slowly passed. Recover the greater part of the ether, by distillation on a water-bath, and expose the residue, in a capsule, until the remaining ether has evaporated. Lastly, keep the oleoresin in a wide-mouthed bottle, well stopped. *U. S.*

The yield is variable, often about 50 per cent. It is of a dark reddish-brown color, and semifluid in consistence, and has the odor and taste of the drug.

Medical Uses.—This preparation probably contains all the medicinal virtues of hop. It is, however, seldom used. It may be prescribed in *doses* of from two to five grains, in pill or capsule.

OLEORESINA PIPERIS, *U. S.*—OLEORESIN OF PEPPER.

Oléorésine de poivre noir, Fr.; *Ätherisches Pfefferextrakt*, G.

Preparation.—Take of Black Pepper in fine powder twelve troyounces; Ether a sufficient quantity. Put the black pepper into a cylindrical percolator, provided with a cork and arranged with cover and receptacle suitable for volatile liquids, press it firmly, and gradually pour ether upon it until twenty fluidounces of liquid have slowly passed. Recover the greater part of the ether by distillation on a water-bath, and expose the residue, in a capsule, until the remaining ether has evaporated, and the deposition of piperin in crystals has ceased. Lastly, separate the oleoresin from the piperin by expression through a muslin strainer, and keep it in a well-stopped bottle. *U. S.*

The officinal process yields about 5 per cent. of a greenish-black oleoresin, consisting of a mixture of volatile and fixed oil holding the pungent resin and some piperina in solution. It is an officinal substitute for the so-called *oil of black pepper*, which is obtained as a by-product in the manufacture of piperina, and has essentially the same composition, except that the volatile oil is present in small quantity only.

Medical Uses.—The medical uses of this oleoresin are probably few and unimportant, since it contains but a small proportion of piperin, which is of some value as a medicine. Its *dose* is one or two minims.

OLEORESINA ZINGIBERIS, *U. S.*—OLEORESIN OF GINGER.

Extractum zingiberis æthereum.—Oléorésine (Piperoide) de gingembre, Fr.; *Ätherisches Ingwerextrakt*, G.

Preparation.—Take of Ginger in fine powder twelve troyounces; Stronger Ether twelve fluidounces; Alcohol a sufficient quantity. Put the ginger into a cylindrical percolator, provided with a cork and arranged with cover and receptacle suitable for volatile liquids, press it firmly, and pour upon it the stronger ether. When this has been absorbed by the powder, add alcohol until twelve fluidounces of liquid have slowly passed. Recover from this the greater part of the ether, by distillation on a water-bath, and expose the residue, in a capsule, until the volatile part has evaporated. Lastly, keep the oleoresin in a well-stopped bottle. *U. S.*

In this process the alcohol is employed for the purpose of displacing the ether, an exception for which there is no good reason, and which might as well be extended to all officinal processes for oleoresins, unless an apparatus, as above described, be used alike for all. Coated ginger yields between 9 and 10 per cent. of the oleoresin; the uncoated (Jamaica) ginger, only between 6 and 7 per cent.; the latter is lighter in color, rather more limpid, and perhaps more agreeable in flavor. The appellation *piperoid* originated with Béral.

Medical Uses.—This oleoresin may possibly fulfil some useful purpose for which ginger in substance and its tincture are inadequate. The oleoresin is, in fact, only a concentrated ethereal tincture. The *dose* is one minim, largely diluted.

OLEUM ÆTHEREUM, *U. S.*—ETHEREAL OIL.

Oleum vini.—Heavy oil of wine, E.; *Huile d'éther, Huile de vin pésante, Huile volatile éthérée*, Fr.; *Schweres Weinöl*, G.

Formula $(C_2H_5)_2SO_4.(C_2H_4)_2SO_3$.

Preparation.—Take of Stronger Alcohol two pints; Sulphuric Acid fifty-five troyounces; Distilled Water a fluidounce; Stronger Ether a sufficient quantity. Add the acid slowly to the alcohol, mix them thoroughly, and allow the mixture to stand for twelve hours. Decant the clear liquid from the sediment into a tubulated retort, of such capacity that the mixture shall nearly fill it. Adapt a thermometer tube to the tubulure by means of a cork, so that the bulb shall be deeply immersed in the liquid, and, having attached a Liebig's condenser, distil, by means of a sand-bath, at a temperature between 302° and 315° F., until the liquid ceases to come over, or until a black froth begins to rise in the retort. Separate the yellow ethereal liquid from the distillate, and expose it for twenty-four hours, in a shallow capsule, to evaporate spontaneously. Then transfer the remaining liquid to a wet filter; and, when the watery portion has drained off, wash the oil which is left, while on the filter, with the distilled water. When this also has drained off, transfer the oil to a graduated measure, by perforating the point of the filter, and add to it an equal volume of stronger ether. The ethereal oil, obtained by this formula, measures about six fluidrachms. *U. S.*

The reaction upon each other of alcohol and sulphuric acid in the production of ether is explained under Æther, page 104, sulphovinic acid, $HC_2H_5SO_4$, being first formed. When this acid is heated with a further supply of alcohol, ether distils over; if water instead of alcohol be added and then heat applied, alcohol distils over, and sulphuric acid is set free; on heating the sulphovinic acid by itself, gas is copiously given off consisting chiefly of *ethylene* (*æthene, elayl, olefiant gas*) C_2H_4, sulphuric acid being regenerated; $HC_2H_5SO_4$ yields C_2H_4 and H_2SO_4, while the free sulphuric acid determines further decomposition, the mass becomes charred, and sulphurous and carbonic acids are met with among the gaseous products. On heating sulphuric acid to about 150° C. (302° F.) and adding slowly sulphovinic acid, heavy oil of wine is produced besides other gaseous compounds and carbonaceous matter.

Instead of operating with pure sulphovinic acid, alcohol and sulphuric acid may be allowed to react upon each other, whereby the products must necessarily be still more complicated, owing to the presence of uncombined alcohol and sulphuric acid, together with water and sulphovinic acid which have resulted from the reaction of the two former; in all cases the temperature to which such mixtures are heated exerts an important influence, determining, as it rises, further decomposition. On keeping sulphuric acid at a temperature of 160° C. (320° F.) and passing the vapors of absolute alcohol into it, Lose obtained ethylene, sulphurous acid, water, and heavy oil of wine, while the retort contained sulphuric, isæthionic, and thiomelanic acids; but on previously diluting the acid with water to the amount of 30 per cent., and using 80 per cent. alcohol, Mitscherlich obtained in the distillate only water and ethylene, with traces of alcohol and ether. The carbonaceous mass mentioned before, has been named *thiomelanic acid;* it is a black, rather dense, glossy mass, forming with bases insoluble compounds, and having a complex composition, approaching the empirical formula $C_{28}H_{16}SO_7$. *Isæthionic acid*, $C_2H_5HSO_4$, is syrupy, and isomeric with sulphovinic acid.

The production of heavy oil of wine evidently depends upon the absence of water and the generation of sulphurous acid, the latter being accompanied by the production of thiomelanic acid. An excess of sulphuric acid is required for this purpose, and this is directed in the above formula, the quantity of acid being about four times greater than is necessary for the production of sulphovinic acid. On mixing the acid and alcohol, a turbidity is seen, and subsequently a white precipitate takes place, consisting of sulphate of lead, which was dissolved in the sulphuric acid; this should be removed to avoid the concussions which would endanger the safety of the retort. When distillation begins, ether and water come over, which are followed by sulphurous acid gas, ethylene, and heavy oil of wine, and the distillate finally consists of an aqueous solution of sulphurous acid and a yellowish ethereal solution of the oil. The gaseous acid should be conducted into the open air, or may be utilized for the preparation of sulphites. By exposing the ethereal portion of the distillate to the air, the ether evaporates, leaving the oil contaminated with some acid watery liquid, which is removed by draining upon a wet filter and washing, after which it is measured and dissolved in an equal volume of ether. This has been found necessary to avoid the spontaneous decomposition and separation into two liquids which would otherwise take place.

The process now officinal is essentially that devised by Squibb (1858), with some modifications suggested by C. L. Diehl (1864). The proper management of the heat influences the yield very considerably; to reduce the formation of ether to its smallest quantity, the mixture should be rapidly heated to near the lowest temperature mentioned in the directions (302° F.), and should never be permitted to fall much below it; if it should rise above 160° C. (320° F.), there is great danger of foaming to such an extent that the mixture will run over and the charge be lost. Diehl found it of advantage to let the temperature rise to 157° or 158° C. (314.6° or 316.4° F.), then to dampen the fire and allow the distillation to proceed spontaneously until the temperature is reduced to 150° C., when heat is again cautiously applied as before, and then heating repeated four or five times until the charge is nearly exhausted, which requires from 10 to 12 hours, when working with 5 to 7 gallons of the mixture. The attention required for smaller quantities is nearly the same. With good management the yield varies between about 1.6 and 2.3 per cent., and averages about 2 per cent. of the weight of the alcohol employed. (See also a paper in *Amer. Journ. Pharm.*, 1865, p. 100.)

Properties.—Pure heavy oil of wine is a yellowish, thickish oily liquid of a peculiar aromatic odor, and pungent, refreshing, bitterish taste, somewhat like that of mint. It is neutral to test-paper, has the specific gravity 1.09, or, according to Serullas 1.133, when quite pure. It is very slightly soluble in water, but dissolves readily in alcohol and ether. On being kept for some time, crystals of *etherin* are separated which have the same elementary composition as ethylene, are nearly tasteless, and on warming have an odor similar to that of oil of wine. In contact with cold water, the oil of wine is slowly, with warm water rapidly decomposed into sulphovinic acid and light oil of wine containing etherin in solution. This *light oil of wine* or *etherol* has likewise the elementary composition of ethylene, but its formula is probably C_8H_{16}; it is yellowish, of a peculiar odor, specific gravity 0.921, insoluble in water, soluble in alcohol. It boils at 280° C. (536° F.), is tough like turpentine at —25° C. (—13° F.), and solid at —35° C. (—31° F.).

Diluted with ether, as directed by the Pharmacopœia, oil of wine has the specific gravity 0.91, a pale-yellowish color, and an ethereal odor, besides that peculiar to the pure oil.

Composition.—Serullas regarded heavy oil of wine as the double sulphate of ether and ethylene, Liebig as ethylsulphate (sulphovinate) of etherol; the latter view appears to be the more correct one if the decomposition with water is taken into consideration. Alkalies also decompose it into sulphovinate of the alkali, liberating etherol. Or it may be related to *sulphuric ether* or *ethylic sulphate*, discovered by Wetherill (1848), which is a yellowish oil of the specific gravity 1.120, has a peppermint-like odor and pungent taste, and the composition of which is expressed by the formula $(C_2H_5)_2SO_4$.

Medical Uses.—It is not used as a medicine except as an ingredient of the compound spirit of ether.

OLEUM AMYGDALÆ AMARÆ, *U. S.*—OIL OF BITTER ALMOND.

Oleum amygdalarum (amararum) æthereum.—Essence d'amandes amères, Fr.; *Bittermandelöl*, G.

Preparation.—Bitter almonds are deprived of most of their fixed oil by pressure between warm plates; the press-cake is powdered, mixed with about six times its weight of water, the mixture digested for a day or two at a temperature of about 50° C. (122° F.), and then distilled.

The oil does not pre-exist in the almonds, but is produced through the decomposition of amygdalin by emulsin, hydrocyanic acid and sugar being at the same time formed; $C_{20}H_{27}NO_{11}$ (amygdalin) and $2H_2O$ yield $C_{12}H_{24}O_{12}$ (glucose), C_7H_6O (oil of bitter almond), and HCN (hydrocyanic acid). This decomposition must first be effected before distillation is resorted to; but while digesting the mixture too high a heat must be avoided, which would coagulate the emulsin and render it ineffective. Distillation by superheated steam is preferable to the use of the naked fire, in order to avoid empyreuma. The water from which the volatile oil has been separated still retains notable quantities of it in solution, which may be recovered by fractional distillation. The yield varies considerably, but is usually in the neighborhood of 1 per cent. The importation of the oil into the United States usually amounts, annually, to 1500 or 2000 pounds.

Properties.—Oil of bitter almond is colorless or yellowish, limpid, has a peculiar aromatic odor, reminding us of that of hydrocyanic acid, and a bitter and burning taste. It varies in spec. grav. between 1.06 and 1.075, and boils at about 180° C. (356° F.). When freed from hydrocyanic acid and rectified, its spec. grav. is lowered to 1.043 or 1.049; but it retains the aromatic almond odor. It is soluble in 300 parts of water, and in all proportions of alcohol and ether.

Composition.—Pure oil of bitter almond was formerly regarded as the hydride of the radical benzoyl (C_7H_5O), but in its chemical relation it is the aldehyd of *benzalcohol*, C_7H_8O, which was discovered by Cannizaro (1853), is a colorless, faintly aromatic oil, and, by careful oxidation, yields *benzaldehyd*, or bitter almond oil, C_7H_6O; and this, by further oxidation on exposure to the air, or by means of oxidizing agents, is converted into benzoic acid, $C_7H_6O_2$. It is this latter compound which crystallizes from old oil of bitter almonds.

Pure benzaldehyd (*artificial oil of bitter almond*) is now largely made in Europe from *toluol*, C_7H_8, a liquid hydrocarbon contained among the products of the destructive distillation of coal.

The crude oil contains variable quantities of *benzimid*, *benzoin*, and *hydrocyanic acid*, from the latter of which it may be freed by agitation with mercuric oxide, or, preferably, ferrous hydrate (a mixture of lime with solution of ferrous sulphate), and subsequent distillation. Potassa and other alkalies may likewise be employed, but an excess is apt to decompose the oil with the production of benzoic acid and benzalcohol. According to Völkel, hydrocyanic acid is contained in the crude oil in the form of a compound, $C_7H_6O.HCN$, which is a yellowish, nearly inodorous bitter oil, of spec. grav. 1.124, and boiling at 170° C. (338° F.). *Benzimid* has the composition $2C_7H_6O.C_7H_6(CN)_2$, and forms, in the pure state, colorless, pearly, inodorous crystals, which, on being boiled with water and hydrochloric acid, are decomposed into oil of bitter almond, formic acid, and ammonia. *Benzoin*, $C_{14}H_{12}O_2$, crystallizes in inodorous and tasteless, colorless prisms, which are polymeric with oil of bitter almond, and are converted into the latter by passing their vapor through a red-hot tube.

Adulterations.—The principal adulterations are nitrobenzol, alcohol, and chloroform, the last two being sometimes used together to leave the specific gravity unchanged. The chloroform is readily detected by distilling a little of the suspected oil from a test-tube placed in a water-bath kept at a temperature not exceeding 65° C. (149° F.), when the chloroform will distil over. *Nitrobenzol* is largely prepared for use in the arts (see page 936), and is met with in the market under the name of *essence de mirbane;* it has an odor similar to that of bitter-almond oil, and a sweet taste, and is nearly insoluble in water. We found it convenient (1857) to test for it by dissolving 15 grains of the oil in 2 drachms of alcohol, adding 15 grains of caustic potassa, heating for a few minutes, evaporating to one-third, and cooling. The pure oil will leave a brownish-yellow liquid, soluble in water, with but slight turbidity; while if nitrobenzol be present, the residue will be dark-brown, sometimes crystalline, and not dissolve clear in water, depositing a brown-yellow sediment in proportion to the amount of the adulterant. The test depends upon the conversion of nitrobenzol, $C_6H_5NO_2$, into *azoxybenzid*, $C_{12}H_{10}N_2O$, which dissolves in alcohol and ether, but is insoluble in water. Wagner (1866) proposed to agitate 5 c. c. of the suspected oil with 10 c. c. of solution of sodium bisulphite, spec. grav. 1.225, and diluting with water to 50 c. c. in a graduated tube; pure bitter-almond oil will dissolve, while the nitrobenzol (spec. grav. 1.20) will separate as an oily layer. More delicate tests for this substance depend upon its reduction to *anilin*. According to Hoffmann (1845) the oil is diluted with ether and some alcohol, after which some zinc and hydrochloric acid are added; after the evolution of hydrogen has ceased, the ethereal layer is evaporated spontaneously, and the residue mixed with a few drops of solution of chlorinated lime, when a purplish-blue color will be produced. Jacquemin (1876) recommended adding a few drops of the oil to a solution of stannous chloride in caustic soda, and afterwards a drop of carbolic acid and some solution of chlorinated soda, when the blue color of erythrophenylate of sodium will appear.

Off. Prep.—Aqua amygdalæ amaræ, *U. S.*

Medical Action and Uses.—The oil of bitter almonds is hardly inferior to dilute hydrocyanic acid in its poisonous power, since one hundred parts of the oil contain nearly thirteen parts of anhydrous hydrocyanic acid. One drop of it has been known to kill a cat. In man, grave and even fatal effects have resulted from a dose of seventeen drops; but, on the other hand, recovery has taken place after the swallowing of half an ounce or more, when remedial measures were at once applied. Medicinally it is one of the best forms in which hydrocyanic acid can be administered, owing to its comparatively stable composition. The proper occasions for its use are indicated under Hydrocyanic Acid. It may be prescribed in doses varying from a quarter of a drop to one drop, and conveniently in mixture of almond.

OLEUM AMYGDALÆ EXPRESSUM, *U. S.*—ALMOND OIL.

Oleum amygdalæ, Br.; *Ol. amygdalæ dulcis, Ol. amygdalarum.—Expressed (sweet) oil of almond*, E.; *Huile d'amandes douces*, Fr.; (*Süsses*) *Mandelöl*, G.

Preparation.—Almond oil is made both from the sweet and bitter almonds. To obtain an unobjectionable oil, the almonds are freed from adhering dust by agitating them upon a sieve and removing discolored pieces, after which they are ground or bruised in an iron or stone mortar, inclosed in canvas bags, and subjected to considerable pressure between polished steel plates, which should not be heated beyond about 30° C. (86° F.). The press cake may be powdered and again expressed, when an additional quantity of oil will be obtained. The yield is 40 to 45 per cent. from sweet, and about 35 per cent. from bitter almonds, a little more when a hydraulic press is used. Expressing the residue at a higher temperature will yield more oil, which, however, is of inferior quality. The expressed turbid oil is set aside in a cool place, and then decanted from the sediment which may be filtered. About 20,000 to 25,000 pounds are annually imported into the United States; in 1867 only 10,544 pounds were entered.

Properties.—The oil is nearly colorless or of a pale straw color, almost inodorous, and has a bland taste. It is a thin fluid, and does not congeal until cooled to about —20° C. (—4° F.); its specific gravity is 0.917 to 0.920; exposed to air it readily turns rancid, but it is not a drying oil. It dissolves in about 30 parts of absolute alcohol, and readily in the usual solvents for fats.

Composition.—It consists mainly of olein, with a small quantity of palmitin. (See Oleum olivæ.)

Adulterations.—Sulphuric acid and chlorinated lime (see p. 950) will detect most of the cheaper oils. But the oils of peach and apricot seeds are very similar to almond oil. Their presence may, however, be shown, according to Hager (1870), by agitating the oil with an equal bulk of 25 per cent. nitric acid, which mixture may be warmed to 60° C. (140° F.) and still remain white or faintly yellowish if the almond oil be pure, but become deeper yellow in proportion to the amount of the other oils present. The two oils mentioned become at once yellowish, and gradually orange-yellow. Bieber (1877) recommended mixing 5 parts of the oil with one part of a cold mixture consisting of equal weights of sulphuric acid, water, and fuming nitric acid. Almond oil gives a yellowish-white mixture; oil of peach-kernels a reddish one, changing to dark orange; benne oil yellowish-red, becoming orange-red.

Off. Prep.—Oleum phosphoratum, *Br.;* Unguentum aquæ rosæ, *U. S.;* Unguent. cetacei, Unguent. hydrarg. oxidi rubri, Unguent. plumbi subacetat. comp., Unguent. simplex, *Br.*

Medical Action and Uses.—The expressed oil of almond is a singularly bland and agreeable oil and very useful as a demulcent. It was formerly used to allay *cough* and all irritations of the respiratory passages. It may be prescribed in an emulsion made with mucilage, or yelk of egg, and white sugar.

OLEUM ANETHI, *Br.*—OIL OF DILL.

Essence d'aneth, Fr.; *Dillöl*, G.

Preparation.—The volatile oil is obtained from the fruit of Anethum graveolens, *Lin.*, by distillation with water. The yield is about 3 to 5 per cent.

Properties.—Oil of dill has a pale yellow color, gradually changing to reddish-brown, the peculiar aromatic odor of the fruit, and a sweetish and warm, afterwards pungent, taste. Its specific gravity varies between .85 and .89, and its rotating power is about 206° to the right. It dissolves iodine with the evolution of some vapors, and is colored red-brown by sulphuric acid.

Composition.—The oil contains a hydrocarbon, *anethene*, $C_{10}H_{16}$, which has an odor resembling that of lemon, and an oxygenated portion which, according to Gladstone (1872), is isomeric or perhaps identical with the *carvol* of oil of caraway. This carvol is obtained by treating the oil with alcoholic solution of ammonium sulphide and decomposing the crystalline compound with an alkali. Both fractions are dextrogyre.

Medical Action and Uses.—Oil of dill is very seldom used in this country; like anise oil, etc., it may be employed to relieve flatulent *colic*, and externally as an anodyne. *Dose*, from two to five drops in hot sugar and water.

OLEUM ANIMALE ÆTHEREUM, *P. G.*—ANIMAL OIL.

Oleum animale Dippelii.—*Dippel's animal oil*, E.; *Huile animale de Dippel*, Fr.; *Ätherisches Thieröl*, G.

Preparation.—On the dry distillation of bones and other animal substances, a fetid, brown, thick, oily liquid is obtained, known as *bone oil, crude*, or *fetid animal oil.* This is purified for medicinal use by distilling it in a retort or flask, which is heated by a sand-bath, as long as a thin oil passes over. This is then mixed with four times its weight of water, and rectified in a metallic still as long as the distillate is colorless, or but slightly yellow. The oily liquid is separated from the water, and at once put into small vials, well corked, and preserved in a dark place. Though previously known and medicinally employed, it was first prepared from dried blood by J. C. Dippel in 1711.

Properties.—*Rectified animal oil* is a colorless or yellowish, thin, oily liquid, which has the average spec. grav. 0.80. It has a very penetrating empyreumatic and ethereal, but not a fetid, odor, and a pungent, acrid, afterwards cooling and bitter taste. It has a slight alkaline reaction to test-paper, dissolves in about 80 parts of water, and is readily soluble in alcohol, ether, fixed and volatile oils. Exposed to light and air it rapidly darkens in color, and acquires a thicker consistence.

Constituents.—This is a very complex mixture, containing a large number of volatile bases like *pyrrol* C_3H_5N, *pyrridin* C_5H_5N, *picolin* C_5H_7O, *lutidin* C_7H_9N, *collidin* $C_8H_{11}N$; also methylamin, propylamin, butylamin, and others. It contains also a neutral liquid which boils at 65.5° C. (150° F.), and different hydrocarbons.

Physiological Action and Medical Uses.—Given to dogs it produces paralysis of the hinder legs and general convulsions. A fluidrachm of this oil destroyed a medium-sized dog in fifteen minutes. Given to man in medicinal doses it excites a sense of warmth in the abdomen, renders the pulse more frequent and stronger, and increases the sweat and urine. A tablespoonful of it is said to have killed a man almost instantaneously; and an ounce and a half, taken by a woman with suicidal intent, caused violent vomiting and intense pain. After death the mouth and throat were dry and shrivelled, and the stomach inflamed and ecchymosed. Formerly the oil was used in the *typhoid state* of febrile affections, in *hysteria*, *epilepsy*, *paralysis*, chronic *rheumatism*, and *sciatica*, and to expel *tapeworms*. Internally it was prescribed in doses of from five to ten drops, and from that to thirty or forty drops, mixed with powdered sugar, or in sulphuric ether, or Hoffmann's anodyne. Externally it was applied by friction, pure or in liniments.

Formerly, a preparation known as Chabert's oil, and which was procured from a mixture of impure empyreumatic oil with oil of turpentine, by distillation, was in high repute as a cure for *tapeworm*. Its offensive taste and smell, and harsh action, caused it to be laid aside when the various tænicide medicines now in use began to be employed.

OLEUM ANISI, *U. S.*, *Br.*—OIL OF ANISE.

Essence d'anis, Fr.; *Anisöl*, G.

The volatile oil distilled from the fruit of Pimpinella anisum, *Lin.*, Woodv. Med. Bot., plate 180, and the oil distilled from the fruit of Illicium anisatum, *Lin.*, Nees, Plant. Med., plate 371. The latter is properly called *Oleum anisi stellati* (*Ol. badiani*); Oil of staranise, *E.;* Huile volatile de badiane, *F.;* Sternanisöl, *G.*

Preparation.—The oil is obtained by distillation of the fruit with water. The yield from anise is 1½ to 2½ per cent.; from staranise 2½ to 4 per cent.

Properties.—Both volatile oils are pale yellow, becoming darker by age, and have a sweet, aromatic taste, and an agreeable aromatic odor, differing somewhat in the two oils. The spec. grav. is .97 to .98, rising in old oils sometimes to 1.028 (Zeller). At a low temperature the oils solidify into a crystallizing mass, the freezing point of the true anise oil being usually near 10° C. (50° F.), and of staranise oil near 2° C. (35.6° F.). It varies, however, very considerably, not only in oils as obtained from different material, but because it changes on keeping, and becomes lower. The reactions of the two oils with the various reagents that have been recommended for the volatile oils, are so similar, that they do not afford any reliable means for distinguishing them. Both are entirely neutral to test-paper, have a very slight right or left rotating power, and are freely soluble in alcohol. The importation of anise oil into the United States increased from 3900 pounds in 1867 to 24,000 pounds in 1876, and 20,500 pounds in 1877.

Composition.—Oil of anise contains a small quantity of a hydrocarbon having the composition $C_{10}H_{16}$, but consists mainly of *anethol*, $C_{10}H_{12}O$, sp. grav. .98; this exists in two modifications, one liquid, the other solid at the ordinary temperature, and fusing at about 20° C. (68° F.), and both boiling between 220° and 225° C. (428° and 437° F.); they are present also in oil of fennel, and a liquid modification in the oil of *Artemisia dracunculus*, Lin., or *tarragon*, has the spec. grav. .945, and boils at 206° C. (402.8° F.). Anethol has a fainter, but more agreeable odor than oil of anise. It is not altered on being boiled with potassa solution; chromic acid converts it into colorless, inodorous, and nearly tasteless crystals of *anisic acid*, $C_8H_8O_3$; nitric acid yields the same compound, or anisoic, anisylic and oxalic acids, according to its concentration and duration of action. Sulphuric acid colors it red, and water separates afterwards inodorous *anisoin;* this is isomeric with anethol, like *metanethol* and *metanethol camphor*, which are produced under certain conditions. Landolph (1875) found Russian oil of anise to contain 90 per cent. of a mixture of anisic aldehyd and anise camphor, to which he gives the formula $C_{10}H_{16}O$.

Adulterations.—Oil of anise has been met with adulterated with alcohol, camphor, wax, and spermaceti; the last three for the purpose of raising its congealing point; camphor is detected in the pressed crystalline mass by its odor, the other two by their insolubility in 80 per cent. alcohol. Leonhardi (1878) reports the oil to be sometimes largely adulterated with the stearopten of Russian fennel oil, which is detected by the fennel odor developed on heating.

Off. Prep.—Essentia anisi, *Br.;* Extr. spigeliæ et sennæ fluid., Spiritus anisi, Syrup. sarsapar. comp. *U. S.;* Tinct. opii ammoniata, *Br.;* Tinct. opii camphorata (camphoræ comp.), *U. S., Br.;* Trochisci glycyrrhizæ et opii, *U. S.*

Medical Action and Uses.—Like other aromatic essential oils, when given to animals in large doses, it occasions lethargy and insensibility. In medicinal doses it acts as a local and general stimulant, and is used to expel *flatus*, allay *colic*, and prevent the griping of drastic purgatives. It has also been employed in the treatment of *chronic bronchitis*, associated with carbonate or muriate of ammonium. It may be prescribed in *doses* of from two to six drops on sugar, or in emulsion.

OLEUM ANTHEMIDIS, *Br.*—OIL OF CHAMOMILE.

Oleum chamomillæ romanæ.—Essence de camomille romaine, Fr.; *Römischkamillenöl*, G.

Preparation.—The volatile oil is obtained from the flowers of Anthemis nobilis, *Lin.*, by distillation with water. The yield is variable, between about $\frac{1}{5}$ and $\frac{1}{2}$ per cent.

Properties.—Fresh flowers seem to yield a blue-colored oil, while that obtained from dried flowers has a green or yellow color; or, if blue, changes rapidly to green and yellow. It has the odor of the flowers, and a warm, aromatic taste; it imparts a red color to litmus paper, and begins to boil at about 160° C. (320° F.), the boiling point rising gradually to above 200° C. (392° F.). It is sometimes distilled from the entire plant, and has then a greenish color, which, on exposure, changes to yellow. Its specific gravity is .90.

Composition.—The oil does not combine with sodium bisulphite. Potassa decomposes it, and B. Jaffé (1865) separated in this way 50 per cent. of impure and 30 per cent. of pure angelicic acid. Demarçay (1875) arrived at the conclusion that it is a mixture of several compound ethers, among which the butylic and amylic angelates and valerianates preponderate.

Off. Prep.—Extractum anthemidis, *Br.*

Medical Action and Uses.—Oil of chamomile is stimulant and antispasmodic, and is used to allay *vomiting*, relieve flatulent *colic*, and to modify the irritant action of cathartics in pill or mixture. It is often added to liniments used for *sprains*, *rheumatic pains*, etc. *Dose*, from one to five drops.

OLEUM BERGAMII, *U. S.*—OIL OF BERGAMOT.

Oleum Bergamottæ, P. G.—Essence de bergamote, Fr.; *Bergamottöl*, G.

The volatile oil obtained from the rind of the fruit of Citrus limetta, *D. C.;* C. bergamia var. vulgaris, *Risso*, s. C. aurantium var. bergamia, *W. & A.* Bentley and Trimen, Med. Plants, 52.

Origin.—The fruit is of a lemon-yellow color, and grows upon a small tree in southern Italy, evidently a variety produced by cultivation; the juice has a bitter and acid taste.

Preparation.—The oil vessels contained in the rind of the fruit are ruptured by means of a machine, wherein the fruit is subjected to a rotatory motion; the oil thus obtained deposits on standing a waxy matter, from which it is decanted. The amount imported into the United States was 41,857 pounds in 1876, and 21,697 pounds in 1877.

Properties.—Oil of bergamot has a green or greenish, sometimes a yellow color, and after rectification is colorless. Its specific gravity varies between .86 and .88, and its boiling point between 183° and 195° C. (351.4° and 383° F.). It has a bitterish aromatic taste, and an agreeable odor, less pleasant after rectification. It has a neutral reaction to test-paper. It dissolves 25 per cent. of carbonbisulphide and 8 per cent. of alcohol, .966, and is soluble in half its weight of alcohol, sp. gr. .85, and in glacial acetic acid. It deviates polarized light to the right from 7° (Pharmacographia) to 40° (Gladstone).

Composition.—The amount of oxygen has been found to vary between 2.6 and 16.14 per cent. in different portions of the distillate. The oil appears to be a mixture of hydrocarbons of the formula $C_{10}H_{16}$ with various hydrates. Distilled with phosphoric anhydrid, a volatile oil of the odor of turpentine is obtained. The waxy matter mentioned above crystallizes from alcohol in silky, colorless, inodorous, and tasteless needles; this *bergamot camphor* or *bergaptene* has the composition $C_9H_6O_3$.

Adulterations.—Oil of bergamot is often adulterated with oil of turpentine and oil of orange, and requires then a larger amount of alcohol for solution. The volatile oils obtained by distillation with water of the leaves and of the nearly exhausted rind, when mixed with oil of bergamot, render it less fragrant.

Medical Action and Uses.—It is a stimulant like other volatile oils, but is seldom employed except for the purpose of scenting ointments and toilet tinctures.

OLEUM BUBULUM.—NEAT'S-FOOT OIL.

Axungia pedum tauri.—Graisse des pieds du gros bétail, Fr.; *Klauenfett*, G.

Preparation.—It is made by boiling neat's feet deprived of their hoofs with water, skimming off the oil which rises to the surface, and keeping it for some time on warm water. After the impurities have settled it is ready for use.

Properties.—Neat's-foot oil is a pale yellow, and, when of good quality, nearly inodorous and tasteless liquid oil, which is but slightly thickened on exposure, does not readily turn rancid, and requires to be cooled to below the freezing point of water before it congeals to a soft white mass. On saponification it yields glycerin and fatty acids, which have not been specially investigated.

Action and Medical Uses.—Neat's-foot oil is much used in softening leather and rendering it pliable. Perhaps this operation may have suggested its administration in medicine as a substitute for cod-liver oil. If it had been efficient, of which there is no proof, its singularly repulsive smell and taste, as usually met with, and its tendency to cause diarrhœa would speedily have condemned it.

OLEUM CAJUPUTI, *U. S.*, *Br.*—OIL OF CAJEPUT.

Oleum cajeputi, P. G.—*Oil of cajuput*, E.; *Essence de cajeput*, Fr.; *Cajaputöl*, G.

The volatile oil obtained from the leaves of Melaleuca cajuputi, *Roxb.* (s. M. minor, *Smith*). Trans. Lond. Med. Bot. Soc.; Steph. and Church, Med. Bot., plate 84; Bentley and Trimen, Med. Plants, 108.

Nat. Ord.—Myrtaceæ.

Origin.—The species mentioned is a small tree, which has lanceolate entire leaves and terminal spikes of small white flowers with exserted stamens. It is indigenous to the East Indian islands. Bentham regards it as a mere variety of *M. leucadendron*, Lin., which extends into Further India, the Philippines, and a considerable portion of Australia, and often attains a moderately large size. The oil is prepared in Celebes, Bouro, and other islands of the Molucca Sea, by distilling the leaves with water. 1146 pounds of cajeput oil entered the United States in 1867, 3150 pounds in 1876, and 1129 pounds in 1877.

Properties.—Oil of cajeput is limpid, of a green color, a penetrating odor, suggesting that of camphor, rosemary, and mint, and a warm, camphoraceous, afterwards cooling taste. The specific gravity varies between .914 and .930; its boiling point is near 173° C. (343.4° F.). It does not congeal at —25° C. (—13° F.), is freely soluble in alcohol, and does not affect litmus paper. It dissolves iodine quietly or with the evolution of few reddish vapors; ammonia turns it yellowish, and sulphuric acid colors it brown, reddish, and finally purplish-brown. By rectification it becomes colorless.

Composition.—Blanchet determined its composition to be $C_{10}H_{16}.H_2O$. Schmidl (1860) obtained, between 175° and 178° C. (347° and 352.4° F.), two-thirds of the oil as a colorless distillate, which has the composition stated, and is the hydrate of a hydrocarbon named *cajeputene*, the latter obtainable by repeated distillation over phosphoric anhydrid. Cajeputene, $C_{10}H_{16}$, boils between 160° and 165° C. (320° and 329° F.), has an agreeable odor of hyacinth, and is slightly soluble in alcohol. Two other hydrocarbons of the same composition and insolubility in alcohol are obtained at the same time, of which *isocajeputene* boils at 176° C. (348.8° F.), and has a less agreeable odor, while *paracajeputene* is thick, yellow, and shows a blue fluorescence. Gladstone (1872) found the hydrate of cajeputene or *cajeputol* also in the volatile oils of *Melaleuca ericifolia* and *linarifolia*, Sm., and of *Eucalyptus oleosa*, F. Muel.; it is dextrogyre, its rotating power varying between 10° and 30°.

The green color of the oil is sometimes, at least, in part due to copper, the presence of which may be proven by agitating the oil with dilute hydrochloric acid and adding to the watery liquid some ferrocyanide of potassium, when a red-brown color or precipitate will occur. However, cajeput oils have been observed which were entirely free from copper, the green being due to chlorophyll.

Adulterations.—The admixture of oil of turpentine is indicated by decreased solubility in alcohol and the more violent reaction with iodine. Imitations made by mixing various volatile oils are detected by the same means and by their different odor. The oils examined by Gladstone cannot, it seems, be distinguished from the officinal.

Off. Prep.—Linimentum crotonis, Spiritus cajuputi, *Br.*

Medical Action and Uses.—This oil has long been prized in the East as a stimulant and diaphoretic medicine, and employed in dropsy, flatulent colic, chronic rheumatism, paralysis, hysteria, etc. It may be used internally as a remedy for *flatulent colic*, particularly when produced by cold or by the retrocession of gout or rheumatism, in *dysmenorrhœa* occasioned by temporary uterine congestion, in *cholera morbus*, and in epidemic *cholera*. In the last named disease it has been largely employed by Oriental physicians. It is of marked utility in cases of *nervous vomiting*, *nervous dysphagia*, *dyspnœa*, and *hiccup*. It has also been used as a *vermifuge*. As a local stimulant and rubefacient it is useful, when diluted with olive oil or added to camphorated liniments, in cases of *functional paralysis* and *muscular rheumatism*. With olive oil or glycerin, it is introduced on cotton into the auditory canal for the relief of *otalgia* and of *deafness*. It is one of the best remedies for *toothache* depending upon caries, when a drop of it upon cotton is introduced into the hollow tooth; and a few drops of it rubbed upon the painful part relieve *nervous headache* and *local neuralgia*. It is a useful stimulant in chronic *scaly affections of the skin*, and in *acne rosacea*. It may be given internally in *doses* of from two to ten drops, on sugar, with Hoffmann's anodyne, or with tinctures or infusions of antispasmodic medicines. As a vermifuge, it may be mixed with honey, in the proportion of one part to thirty or more, and dessertspoonful doses of the mixture may be given every hour or two. It may also be administered by enema.

OLEUM CAMPHORÆ, *U. S.*—OIL OF CAMPHOR.

Huile volatile de camphre, Fr.; *Flüchtiges Kampferöl*, G.

The volatile oil obtained from Camphora officinarum, *Nees.*

Origin.—The oil is obtained in the preparation of crude camphor, a portion also in refining this product (see page 329). It is known in commerce as camphor oil of Formosa.

Properties.—It is a dark wine-yellow or yellowish-brown liquid, having a camphor-like odor and taste, and the specific gravity .940. At a low temperature, it deposits a considerable quantity of camphor in the form of crystals, and at about 180° C. (356° F.), it begins to boil. It turns the plane of polarized light to the right.

Composition.—By careful fractional distillation, a considerable portion of camphor is left in the retort, but cannot be completely removed by this means. The liquid distillate has, according to Martius, the odor of camphor and cajeput, and, according to Mulder, is a solution of laurel camphor, $C_{10}H_{16}O$, in a hydrocarbon of the composition $C_{10}H_{16}$.

CAMPHOR OIL OF BORNEO is obtained from *Dryobalanops camphora*, Colebr. (see page 330), by tapping or felling the tree. It is a rather viscid brown-yellow or reddish oil, which is a solution of resin and some Borneo camphor, $C_{10}H_{18}O$, in a hydrocarbon, $C_{10}H_{16}$; the latter has a terebinthinate odor, and is identical with the hydrocarbon of oil of valerian, hence the names *borneene* and *valerene*. The crude oil is dextrogyre, begins to boil at about 165° C. (329° F.), and deposits little or no camphor when placed in a freezing mixture. It is rarely, if ever, met with in commerce.

Medical Action and Uses.—Oil of camphor (which should not be confounded with camphorated oil) possesses properties identical with those of camphor, and may be used for similar purposes; but it is very seldom employed. The *dose* is two or three drops.

OLEUM CARI, *U. S.*—OIL OF CARAWAY.

Oleum carui, Br.; *Oleum carvi*, P. G.—*Essence de carvi*, Fr.; *Kümmelöl*, G.

Preparation.—The volatile oil is obtained from the fruit of Carum carui, *Lin.*, by distilling it with water; the yield is variable, but averages about 4 per cent. The fruit which is grown in northern countries is generally richer in oil than that from more southern localities. 3600 pounds passed into the United States in 1867, 6614 pounds in 1876, and 5528 pounds in 1877.

Properties.—Oil of caraway is limpid, colorless or pale yellow, becoming brown and viscid on exposure. Its specific gravity is usually about .91 or .92, but in old oil may rise to .97. When fresh it has no action on litmus; its odor is agreeable; its taste burning aromatic. It dissolves readily in alcohol, turns polarized light to the right, and commences to boil at 190° C. (374° F.).

An inferior oil of caraway is made from the refuse or "chaff" of the fruit; it is less agreeable in odor, and not unfrequently mixed with oil of turpentine.

Composition.—By repeated fractional distillation, Völkel (1840) separated *carvene*, $C_{10}H_{16}$, which has little odor and taste, and boils at 173° C. (343.4°

F.), and *carvol*, $C_{10}H_{14}O$, which is liquid, has an agreeable odor, and boils at 227° C. (440.6° F.) (*Gladstone*) or at 250° C. (482° F.) (*Varrentrapp*). In contact with alcoholic solution of ammonium sulphide, it yields white silky needles of $2(C_{10}H_{14}O).H_2S$, from which carvol is again separated by potassa. Carvol (see also Ol. anethi) is isomeric with menthol of spearmint, myristicol of nutmeg, thymol, cuminic alcohol, and *carvacrol;* the latter is a rather viscid, colorless, or yellowish oil, resembling creasote in odor and taste, and may be obtained by distilling a mixture of oil of caraway and potassa until carvene has been expelled, decomposing the residue by sulphuric acid, and rectifying the oil.

Off. Prep.—Confect. scammonii, *Br.;* Extr. spigeliæ et sennæ fluid., *U. S.;* Pilula aloes barbad., *Br.;* Spirit. juniperi comp., *U. S.*

Medical Action and Uses.—The properties of this oil are nearly identical with those of oil of anise. Given to animals in large doses it causes death by asthenia. It may be used in the treatment of *flatulent colic*, and whenever a gastric stimulant or a carminative is required. Locally it acts, like other essential oils, as an anæsthetic. It may be administered in sweetened water, ether, or Hoffmann's anodyne, in the *dose* of from one to ten drops.

OLEUM CARYOPHYLLI, *U. S.*, *Br.*—OIL OF CLOVES.

Oleum caryophyllorum, P. G.—*Essence de girofles*, Fr.; *Nelkenöl*, G.

Preparation.—The volatile oil is obtained from cloves, the flower-buds of Caryophyllus aromaticus, *Lin.*, by distilling them with water. For this purpose the cloves require to be bruised, cohobation should be repeatedly resorted to, and salt may be added (see page 945) in order to raise the boiling point. If the cloves have been properly bruised, the three or four times repeated distillation of the water from the same cloves is usually sufficient; but, if the powder be very coarse, the distillation will have to be repeated more frequently. At first the oil coming over is chiefly the light portion which floats on the water; afterwards the heavy portion distils, and the two portions united constitute the commercial article. The yield is 15 to 20 per cent. Clove stalks are said to be sometimes used in Europe in the distillation of this oil. In the United States, cloves from South America are employed for distilling the oil, and the entire want is now supplied in this country. In 1867 the amount imported was 956 pounds, which decreased in 1877 to 2 pounds.

Properties.—When recently distilled, oil of cloves is of a pale yellow color, but becomes darker and finally brown-yellow on keeping. It has a strong odor of cloves, a burning aromatic taste, and boils at 240° C. (455° F.). Its specific gravity varies between 1.034 and 1.056; oil of clove stalks, though agreeing in odor, has a density of about 1.009. Oil of cloves dissolves freely in alcohol, the solution having a slight acid reaction, and yielding with ferric chloride a purplish-blue color. Sulphuric acid colors the oil blood-red, finally blue; iodine dissolves in it quietly; strong potassa solution converts it into a crystalline mass of eugenate of potassium; and fuming nitric acid acts violently upon it, sometimes with ignition. The oil is without action or with but slight action (—4°, Gladstone) upon polarized light.

Composition.—On distilling a mixture of oil of cloves with excess of potassa, the colorless distillate is the *light oil of cloves*, and has the composition $C_{10}H_{16}$; its odor is distinct from that of cloves, more terebinthinate; it has the density .91, and boils at 251° C. (483.8° F.). On decomposing the eugenate of potassium with sulphuric acid and rectifying the separated oil, *eugenic acid* or *eugenol*, $C_{10}H_{12}O_2$, is obtained as a colorless oil having the odor of cloves, the specific gravity 1.076 (Stenhouse), and, according to Williams, the same boiling point as the preceding hydrocarbon; it yields with bases crystallizable salts, which, with the exception of the barium compound, are decomposed by much water or alcohol, and are colored blue or purple by ferric salts. By treating it in an atmosphere of carbonic acid with sodium, Scheuch (1863) obtained the sodium salt of *eugetinic acid*, $C_{11}H_{12}O_4$, which is crystallizable, soluble in water, colors ferric salts deep blue, and is decomposed by heat into carbonic and eugenic acids. The same author proved likewise the presence in oil of cloves of salicylic acid, most probably in the form of an ether.

Adulterations.—The determination of the boiling point and the specific gravity are sufficient for detecting most adulterations to which oil of cloves is sometimes subject; on treating the suspected oil with alcoholic solution of potassa the odor of cloves disappears, and the nature of the adulteration is established. For the detection of carbolic acid, Jacquemin (1875) recommended adding a trace of anilin, shaking with water, and adding a little chlorinated soda, when a blue color will be produced. Flückiger (1870) proposed to shake 1 part of oil with 50 parts of hot water, concentrate the aqueous liquid by evaporation at a moderate heat, add a drop of ammonia and a little chlorinated lime; in the presence of carbolic acid a green color passing into blue will be produced.

Off. Prep.—Confect. scammonii, Pil. colocynth. comp., Pil. colocynth. et hyoscyami, *Br.*

Medical Action and Uses.—The action and uses of oil of cloves are essentially the same as those of the oils of caraway and anise. It is seldom employed internally, but is sometimes used to allay the pain of *carious teeth*, and of *earache*.

OLEUM CHENOPODII, *U. S.*—OIL OF WORMSEED.

Essence de chénopode anthelmintique, Fr.; *Amerikanisches Wurmsamenöl*, G.

Preparation.—The volatile oil is obtained from the fruit of Chenopodium anthelminticum, *Lin.*, by distilling it with water. Much of the oil is distilled in Maryland, and in some of the Western States. The fruit yields about 3 to 3½ per cent., the fresh herb ½ to 1 per cent. The Western oil is rather less pungent than the Baltimore oil of wormseed.

Properties.—Oil of wormseed is colorless or yellowish, limpid, becoming brown and thick on exposure. It has the peculiar odor of wormseed, and a bitterish, pungent, and somewhat cooling taste. Its specific gravity, when fresh, is .902 to .91, and increases by age to .960. It boils at 180° to 190° C. (356° to 374° F.), dissolves iodine slowly, and turns brown-red when boiled with nitroprusside of copper.

Composition.—Garrigues (1854) found oil of wormseed to be a mixture of a hydrocarbon, $C_{10}H_{16}$, and a liquid oxygenated oil, $C_{10}H_{16}O$. The former has the density .932, boils near 176° C. (350.6° F.), and yields a liquid and a crystalline compound with chlorine. The specific gravity of the latter is .987, its boiling point 245° C. (473° F.).

Medical Uses.—Wormseed oil is almost exclusively used as an anthelmintic, although occasionally employed for the cure of *intermittent fever*, *hysteria*, *chorea*, and other *nervous affections*. In America it is one of the most popular remedies for *lumbricoid worms;* but it has also been used successfully to expel *tæniæ*. It is true that in Europe some observers have tended to discredit its efficacy, and even in this country there is more evidence of its utility in cases of gastro-intestinal *dyspepsia* among children, which often is mistaken for verminous disease, than of its direct vermifuge powers. It may be given to children in *doses* of from five to ten drops, on sugar, and repeated twice daily for several days, when it should be followed by a dose of castor oil.

OLEUM CINNAMOMI, *U. S.*, *Br.*—OIL OF CINNAMON.

Oleum cinnamomi zeylanici, P. G.—*Oil of Ceylon cinnamon*, E.; *Essence de cannelle*, F.; *Zeylonisches Zimmtöl*, G.

Preparation.—The Pharmacopœia recognizes only the volatile oil of Ceylon cinnamon, which is almost exclusively prepared in Ceylon by distilling the chips and refuse bark with water. However, judging from the custom-house entries, but little of the oil is imported into the United States. The importation in 1867 amounted to 46 pounds; in 1877 to 15 pounds; while 20,685 pounds of oil of Chinese cinnamon (or Cinnamon cassia) were imported in 1867, and an annual average of 43,129 pounds during the three years ending June 30, 1877. The latter oil is sometimes distilled in the United States. Ceylon cinnamon yields ½ to 1 per cent., Chinese cinnamon ½ to 1½ per cent. of volatile oil.

Properties.—OIL OF CEYLON CINNAMON is a pale-yellow or reddish liquid, becoming red-brown and thicker on exposure, finally separating crystals of cinnamic acid. It has a strong but agreeable cinnamon odor, and a sweet and at the same time hot, aromatic taste. Its specific gravity varies between 1.035 and 1.055, and increases by age. It remains clear at the freezing point of water, but at a still lower temperature separates a stearopten; it has no action on polarized light, or shows a slight left rotation, is readily soluble in alcohol, and has a neutral reaction on litmus paper when fresh, and an acid reaction when old. It dissolves iodine almost quietly, and soon forms a thick mass; fuming nitric acid imparts to it a carmine color without causing effervescence; boiling with nitroprusside of copper turns it red, then dark-brown; its alcoholic solution is somewhat darkened by ferric chloride.

OIL OF CASSIA (*Chinese cinnamon*) resembles the preceding oil very closely in all its properties, except that its color is more brownish, its odor less delicate, its taste less sweet, and its specific gravity greater, being usually 1.060 to 1.065; sometimes it is slightly dextrogyre.

Composition.—Both oils contain variable quantities of hydrocarbon, but consist chiefly of *cinnamic aldehyd*, C_9H_8O; and, when old, also resin and cinnamic acid, $C_9H_8O_2$. In its pure state, cinnamaldehyd is a colorless oil, heavier than water, combines with strong nitric acid in the cold, forming crystals, which are soluble in alcohol and ether, decomposed by water, and, when heated, yield oil of bitter almond and benzoic acid. Oxidizing agents generally, when acting upon cinnamaldehyd, generate the odor of bitter almonds, and finally produce benzoic acid; heated with solid potassium hydrate, potassium cinnamate is formed, hydrogen being given off; $C_9H_8O + KHO$ yields $C_9H_7KO_2 + H_2$. *Cinnamic acid* crystallizes in shining, colorless prisms, which are inodorous, dissolve freely in alcohol, ether, and boiling water, fuse at about 130° C. (266° F.), boil and volatilize without decomposition at about 295° C. (563° F.), and it is oxidized by chlorinated lime and hot dilute nitric acid to oil of bitter almond and benzoic acid.

Adulterations.—Oil of cinnamon is sometimes mixed with oil of cassia, which is best detected by the difference in their physical properties pointed out above. An adulteration with oil of cloves cannot be detected by the odor, except on heating, when acrid vapors will be given off. The behavior to ferric chloride and cold fuming nitric acid, afford additional means for detection.

Off. Prep.—Aqua cinnamomi, Spiritus cinnamomi, *U. S.*

Medical Action and Uses.—Excessive doses of this oil given to rabbits produce violent action of the heart, hurried respiration, distress, evacuation of solid feces, insensibility, slow and labored respiration, cold extremities, and death. The gastro-intestinal mucous membrane is not inflamed. The oil is much employed to give an agreeable flavor to medicinal compounds, and render them acceptable to the stomach. If the virtues attributed to cinnamon (see Cinnamomum) in uterine hemorrhage are real, they would probably be displayed more efficiently by the oil than by any other preparation of the medicine.

OLEUM COCOIS, *P. G.*—COCOANUT OIL.

Cocoanut butter, E.; *Beurre de coco*, Fr.; *Kokosnussöl*, G.

From Cocos nucifera, *Lin.* *Nat. Ord.*—Palmæ.

Origin.—The cocoanut tree is now met with in all tropical countries. It grows to a height of 70 or 80 feet, and has at the apex a tuft of leaves, which are 12 feet and more long, and have numerous narrow rigid and long leaflets. The yellowish-white flowers produce the well-known cocoanuts, which in their unripe state contain a sweetish liquid. The seeds contain much fixed oil, which is obtained by hot pressure or on being boiled in water. Nearly 267,000 gallons of cocoanut oil were imported into the United States in the year 1876–1877.

Properties.—Cocoanut oil is of a butyraceous consistence, white, and has a peculiar disagreeable odor, which is also observed in the soap prepared with it. It fuses at about 23° C. (73.4° F.) to a thin transparent oil, congeals again near 18° C. (64.4° F.), and on exposure to the air becomes rancid.

Composition.—By cold pressure it may be separated into a liquid and solid portion, both of which are glycerides. According to Görgey and Oudemans, the acids contained in cocoanut oil are palmitic and myristic, but principally lauric acid, together with caprinic, caprylic, and capronic acids.

Medical Action and Uses.—Cocoanut oil has been tried as a substitute for cod-liver oil, but, like other succedanea for that oil, was found inefficient. It was given in tablespoonful doses. It is chiefly valuable for its economical and pharmaceutical uses.

OLEUM COPAIBÆ, *U. S.*, *Br.*—OIL OF COPAIBA.

Oleum balsami copaivæ.—Essence de copahu, Fr; *Copaibaöl*, G.

Preparation.—The oil is obtained by distilling copaiba with water, a metallic still being preferable to a glass retort; a considerable quantity of water, or preferably steam should be used, or the distilled water returned to the still, until all the oil has been obtained. All that is consumed in the United States is prepared here from Para copaiba, which yields 50 to 60 per cent., or even more.

Properties.—Oil of copaiba is limpid, colorless, or pale yellowish, and on exposure becomes slowly thicker and yellow. It has the odor of copaiba, a pungent bitterish taste, neutral reaction to test-paper, spec. grav. .88 to .91, and boils at about 250° C. (482° F.). It dissolves in about 40 parts of alcohol spec. grav. .85, mixes with iodine without violent reaction, and yields with hydrochloric acid gas a liquid and a crystallizable compound. It deviates polarized light to the left.

Composition.—The oil has the composition of oil of turpentine, $C_{10}H_{16}$, and consists of several isomeric modifications.

Adulterations.—The addition of oil of turpentine is detected by the odor, and by the more violent reaction with iodine.

Medical Action and Uses.—Oil of copaiba is poisonous to rabbits in doses of an ounce or more. The symptoms produced by it are hurried breathing, palpitation, restlessness, frequent micturition, diarrhœa with mucous or bloody stools, and death by asthenia. After death a partial destruction of the gastro-intestinal epithelium is the only lesion observed. Upon the human skin it acts very feebly as an irritant. When taken internally it is excreted by the urine, which then furnishes a precipitate with nitric or muriatic acid. It is very doubtful whether this oil has any efficient control over *gonorrhœa*, the disease for which copaiba itself is chiefly employed. It probably is more useful in chronic pulmonary catarrh, or *chronic bronchitis*, since it is apparently through the lungs that the odorous constituent of all oleoresins is eliminated. But clinical evidence upon this point is wanting, unless, indeed, the negative proof afforded by the silence of all competent authorities be accepted as sufficient. The *dose* of the oil is from ten to fifteen drops.

OLEUM CORIANDRI, *Br.*—OIL OF CORIANDER.

Essence de coriandre, Fr.; *Korianderöl*, G.

Preparation.—The volatile oil is obtained from the bruised fruit of Coriandrum sativum, *Lin.*, by distilling it with water. The yield is about ½ per cent.

Properties.—It is colorless or pale yellow, has a mild and agreeable aromatic odor and taste, a spec. grav. of .86 to .87, commences to boil at about 150° C. (302° F.), and dissolves readily in alcohol. Iodine and fuming nitric acid act energetically upon it, the latter producing a greenish resin.

Composition.—The oil has the composition $C_{10}H_{18}O$, and is isomeric with borneol. From Kawalier's investigations (1852), it appears sometimes to contain also a hydrocarbon, $C_{10}H_{16}$.

Adulteration.—Leonhardi (1878) mentions oil of orange, which is detected by its insolubility in an equal bulk of 85 per cent. alcohol.

Off. Prep.—Syrupus sennæ, *Br.*

Medical Action and Uses.—Like oil of anise, fennel, etc., this oil is aromatic and carminative, and is used in flatulent *colic*, to relieve the pain of *rheumatism*, *neuralgia*, etc., and to mitigate the griping operation of certain purgatives. It corrects the odor and taste of fluid extract of senna better than any other aromatic. *Dose*, one to five drops.

OLEUM CUBEBÆ, *U. S.*, *Br.*—OIL OF CUBEB.

Oleum cubebarum.—*Oil of cubebs*, E.; *Essence de cubèbes*, Fr.; *Kubebenöl*, G.

Preparation.—The volatile oil is obtained from the bruised fruit of Cubeba officinalis, *Miq.*, by distilling it with water, repeated cohobation being necessary. The yield is about 10 per cent, but varies considerably with the quality of the fruit. It is distilled in the United States, little being imported; in 1867, 558 pounds, none in 1876, and only 5 pounds in 1877.

Properties.—Oil of cubebs has a greenish or yellowish tint, but after rectification is colorless, and, on exposure, becomes thick like olive oil. It has the odor of cubebs, a warm, camphoraceous, aromatic taste; spec. grav. .92; a neutral reaction; boils at about 250° C. (482° F.); dissolves in 25 parts of alcohol, and turns polarized light to the left. Iodine dissolves in the oil quietly, but evolves some vapors; concentrated sulphuric acid colors it yellow, and, on warming, red.

Composition.—Oil of cubebs consists chiefly of *cubebene* $C_{10}H_{16}$, or perhaps $C_{30}H_{48}$, and in the cold sometimes separates crystals of *cubeb camphor*, which is a hydrate of the former, of the formula $C_{30}H_{48}.2H_2O$, and fuses below 70° C. (158° F.).

Medical Action and Uses.—In the dose of an ounce oil of cubeb produces symptoms in rabbits almost identical with those of oil of copaiba, but more strongly marked. In man it causes, occasionally, an eruption, as copaiba does. It displays no curative virtues in gonorrhœa. The *dose* is from ten to fifteen drops or more.

OLEUM ERIGERONTIS CANADENSIS, *U. S.*—OIL OF CANADA ERIGERON.

Preparation.—The volatile oil is obtained in the United States from the fresh flowering herb of Erigeron canadense, *Lin.*, by distilling it with water.

Properties.—Oil of erigeron is a limpid, pale-yellow liquid, of a peculiar aromatic, persistent odor, somewhat like that of hemlock (Abies canadensis), and of an aromatic, not very pungent taste. It has the spec. grav. .845, and commences to boil at about 155° C. (311° F.) It dissolves iodine without explosion, is gradually colored reddish by potassa, and slowly acted on in the cold by fuming nitric acid. The oil becomes thick and reddish-brown by age, and is not very freely soluble in 80 per cent. alcohol.

Composition.—Nothing is known of its constituents, except that it contains oxygen, as ascertained by Procter (1854).

Medical Action and Uses.—This oil has had a certain reputation for controlling uterine hemorrhage, and the plant from which it is derived was held by the aborigines to quicken *uterine contractions.* The evidence respecting its virtues is conflicting, and seems, on the whole, not adapted to inspire much confidence. Like other nervo-vascular stimulants it is said to have been useful in the *typhoid state.* The *dose* is from five to ten drops.

OLEUM FŒNICULI, *U. S.*—OIL OF FENNEL.

Essence de fenouil, Fr.; *Fenchelöl*, G.

Preparation.—The volatile oil is obtained from bruised fennel by distilling it with water, or preferably, by means of superheated steam. The yield is about 3½ or 4 per cent. The oil used in the United States is chiefly procured from Germany and France.

Properties.—Oil of fennel is colorless or yellowish, has a neutral reaction, an agreeable odor, a sweetish, aromatic taste (*oil of sweet fennel*), and is of the spec. grav. .96 to .99; it congeals below 10° C. (50° F.), sometimes not until cooled below the freezing point of water, and Zeller obtained an oil which remained liquid at —20° C. (—4° F.). Boiled with nitroprusside of copper, it turns yellowish-brown or red-brown; on the addition of iodine it becomes thick like an extract, or even brittle. It is soluble in 1 or 2 parts of alcohol, and turns the ray of polarized light to the right.

Composition.—The difference in the physical properties is due to the variable proportion of liquid and solid *anethol* contained in it (see Ol. anisi, page 962). The oil also contains a hydrocarbon, isomeric with oil of turpentine.

Off. Prep.—Aqua fœniculi, Spiritus juniperi comp., *U. S.*

Medical Action and Uses.—The action of fennel oil when given to animals in large doses appears to be identical with that of oil of anise. Its medicinal operation closely resembles that of the same oil. It is used in *flatulent* disorders and to qualify the action of harsh purgatives, and is sometimes employed as a *galactagogue*, and as an *emmenagogue.* The *dose* is from five to ten drops.

OLEUM GAULTHERIÆ, *U. S.*—OIL OF GAULTHERIA.

Oil of wintergreen, E.

Preparation.—This volatile oil is obtained from Gaultheria procumbens, *Lin.*, the whole plant being usually employed. The chief supply is derived from New Jersey, but some is also prepared in Pennsylvania and other States.

Properties.—Oil of gaultheria is usually of a reddish color, but may be obtained colorless by rectification. It has a strong and agreeable aromatic odor and a sweetish warm aromatic taste, and begins to boil a little above 200° C. (392° F.). It is the heaviest of the volatile oils, its density being 1.17 to 1.18. It is slightly dextrogyre, and dissolves readily in alcohol, and but to a small degree in water; the solutions acquire a dark purple color on the addition of ferric chloride. The pure oil is not colored on the addition of strong nitric acid, but soon congeals into colorless crystals of a nitro-compound. A solid crystalline mass is also obtained on agitating the oil with concentrated solution of potassa or soda.

Composition.—Procter (1842) recognized the presence in this oil of salicylic acid. Cahours subsequently (1843) proved it to consist to the amount of about 90 per cent. of *methylsalicylic acid* or *methylsalicylic ether*, $CH_3.C_7H_5O_3$, which with some other salicylic ethers is now also artifically prepared for use in the arts. In its pure state it is a colorless oil, has the spec. grav. 1.18, boils at 222° C. (431.6° F.), and forms crystalline compounds with the alkalies. The remaining constituent of oil of wintergreen is *gaultherilene*, a colorless thin hydrocarbon, of the formula $C_{10}H_{16}$, boiling at 160° C. (320° F.), and having an agreeable somewhat pepper-like odor. Volatile oils of similar composition have been obtained from Gaultheria hispidula, Polygala pauciflora, Monotropa hypopitys, and the bark of Betula lenta.

Adulterations.—The great density of this volatile oil prevents its adulteration with most cheaper ones, which would reduce its specific gravity. A mixture of alcohol and chloroform has been employed for the purpose, but is readily detected by the low boiling point and the character of the first fractional distillate. The most common adulterant is oil of sassafras, which is colored dark red and converted into a brown-red resinous mass by strong nitric acid. The pure oil yields nearly colorless crystals of *methylnitrosalicylic acid*.

Off. Prep.—Syrup. sarsapar. comp., Trochisci morphiæ et ipecacuanhæ, *U. S.*

Medical Action and Uses.—Its action in large doses closely resembles that of the other aromatic essential oils. In the case of a boy nine years old half an ounce of it occasioned vomiting, purging, epigastric pain, fever, labored and slow respiration, dulness of hearing, and an uncontrollable desire for food. It is sometimes used as a carminative, but most frequently to conceal the taste of nauseous medicines. It assists in flavoring the compound syrup of sarsaparilla.

OLEUM HEDEOMÆ, *U. S.*—OIL OF HEDEOMA.

Oil of pennyroyal, E.

Preparation.—This volatile oil is prepared in New Jersey and other parts of the United States by distilling the fresh herb of Hedeoma pulegioides, *Lin.*, with water.

Properties.—It is a limpid, colorless, or yellowish volatile oil, of a peculiar pungent mintlike odor and taste, and has a specific gravity of .94 to .95. It is readily soluble in alcohol, and dissolves iodine with a brisk explosive reaction, yielding a viscous liquid.

Composition.—Oil of pennyroyal contains oxygen, but its exact composition has not been ascertained.

Medical Action and Uses.—It has essentially the same action and virtues as the associated volatile oils; that is to say, it is an aromatic stimulant, carminative, and emmenagogue under fit conditions, and is added to embrocations to increase their anodyne and rubefacient action. The *dose* is from two to ten drops.

OLEUM JUNIPERI, *U. S.*, *Br.*—OIL OF JUNIPER.

Oleum fructus (vel baccæ) juniperi.—Oil of juniper berries, E.; *Essence de genièvre*, Fr.; *Wachholderbeeröl*, G.

Preparation.—Ripe or nearly ripe juniper berries are well bruised, mixed with table salt and water, and distilled either over the naked fire, or by the aid of steam. The yield is usually half to three-quarters per cent., and sometimes exceeds one per cent. Between 5000 and 6000 pounds are annually imported from Europe into the United States.

Properties.—Oil of juniper berries is colorless, or pale greenish yellow, limpid, but on exposure rapidly thickens, and turns yellow and reddish-brown. Its specific gravity varies between .85 and .90; it begins to boil at 155° C. (311° F.), or if obtained from ripe berries at 205° C. (401° F.) (*Blanchet*), has the peculiar odor of the berries, and a warm aromatic, somewhat terebinthinate taste, turns polarized light slightly to the left, is slightly soluble in 80 per cent. alcohol, and shows a neutral reaction to test-paper. Iodine acts energetically upon the limpid oil, sometimes producing fulmination; sulphuric acid colors it brown and red. Old oil of juniper contains formic acid, from which it may be freed by sodium carbonate and rectification.

Composition.—The oil is a mixture of hydrocarbons of the general formula $C_{10}H_{16}$, which differ in their boiling point (see above), a portion boiling at 282° C. (539.6° F.), (*Soubeiran and Capitaine*). It yields with hydrochloric acid gas a liquid compound.

Adulteration.—The similarity of oil of juniper and oil of turpentine in specific gravity, boiling point, and behavior to solvents and reagents, renders the detection of an adulteration with the latter rather difficult, except by the formation of a solid compound with hydrochloric acid gas and by its different odor, particularly after exposure.

The *oil of juniper wood*, obtained by distillation with water, has a different odor, and is at first limpid and colorless, but on exposure becomes thick, yellow, and finally dark brown.

Oleum juniperi empyreumaticum, P. G., s. *Oleum cadinum; Oil of cade*, E.; *Huile de cade*, Fr.; *Kadeöl*, G., is an empyreumatic, dark-brown, tarlike liquid obtained from the wood of Juniperus oxycedrus, *Lin.* The empyreumatic oil of common juniper wood is said to be frequently sold in its place.

Off. Prep.—Spiritus juniperi, *U. S.*, *Br.;* Spiritus juniperi comp., *U. S.*

Medical Action and Uses.—Oil of juniper is stomachic, carminative, and diuretic. In large doses it occasions in animals the same effects upon the nervous and vascular systems as other essential oils, with the addition of diuresis. The last-mentioned operation is evident in man as an effect of medicinal doses. It reddens and may even blister the skin. It is an efficient ingredient of diuretic infusions and mixtures, is much used to promote urination, in the form of Holland gin, and when inhaled from an atomized solution its diuretic virtues are sometimes promptly and distinctly manifested. The *dose* is from five to fifteen drops.

OLEUM LAVANDULÆ, *U. S.*, *Br.*—OIL OF LAVENDER.

Essence de lavande, Fr.; *Lavendelöl*, G.

Preparation.—Oil of lavender is distilled in Great Britain and France from the flowers alone, or from the flowering tops or the entire plant of Lavandula vera, *D. C.*, steam heat being usually resorted to. The flowers yield about one and a half per cent. of the oil; the quantity however varies, and seems to increase in plants grown in southern localities. Stem and leaves yield a small portion of less fragrant oil. Between 30,000 and 35,000 pounds are annually imported into the United States.

Properties.—The oil is very limpid, colorless, yellowish, or greenish yellow and neutral, and acquires by age an acid reaction and viscid consistence. Its specific gravity varies between .87 and .91; it commences to boil at about 185° C. (365° F.), dissolves in its own weight of alcohol, specific gravity .835 to .850, has a lævogyre action, reacts briskly and with some detonation on the addition of iodine, and acquires a brown color when agitated with corrosive sublimate. Exposed to a low temperature it separates stearopten. Its fragrance varies with the part of the plant used for distillation; its taste is bitterish and pungent. The better quality is known in commerce as *oil of garden lavender*.

Composition.—The most volatile portion is a hydrocarbon of the formula $C_{10}H_{16}$. The stearopten is stated by Dumas to be identical with camphor.

Adulteration.—The admixture of oil of turpentine is detected by the decreased solubility in alcohol. Oil of spike lavender has a deeper green-yellow color, and a more terebinthinate camphoraceous odor, but agrees with oil of lavender in solubility.

Off. Prep.—Liniment. camphoræ comp., *Br.;* Spiritus ammoniæ aromat., *U. S.;* Spiritus lavandulæ, Spiritus (Tinctura) lavandulæ comp., *U. S.*, *Br.*

Medical Action and Uses.—This preparation is very seldom used alone, although it may be employed to calm *nervous headache*, by rubbing a few drops of it upon the temples, or by its internal use in the dose of four or five drops. Its carminative and general stimulant operation is usually obtained through the simple and compound spirit of lavender.

OLEUM LIMONIS, *U. S.*, *Br.*—OIL OF LEMON.

Oleum citri, P. G.; *Oleum de cedro.*—*Essence de citron*, Fr.; *Citronenöl*, G.

Preparation.—The volatile oil is obtained from the fresh rind of the lemon by squeezing it upon a sponge, and expressing the latter when saturated; or the oil-cells are ruptured by a process of superficial grating, the oil being drained off. An oil of inferior fragrance is obtained by grating the outer rind completely off and distilling the magma with water. Oil of lemon is manufactured in Southern France and Italy. In 1867, 34,227 pounds of oil of lemon and orange were imported by the United States, against 67,585 pounds in 1877.

Properties.—Oil of lemon has a pale yellow color, is limpid, neutral, of a very agreeable fragrance, and mild, aromatic, bitterish taste. As received in commerce, it is usually turbid, but becomes clear on standing; by age, it acquires a thicker consistence and a pungent terebinthinate odor and taste, which change is prevented or retarded by the addition of 3 or 4 per cent. of alcohol and decantation of the clear oil from the sediment. Its specific gravity is about .852; it commences to boil at about 160° C. (320° F.), rotates polarized light to the right, produces a brisk fulmination with iodine, yields with Frœhde's reagent a deep orange-brown color (Dragendorff, 1876), and by hydrochloric acid gas is converted into a liquid and a solid compound, which, distilled over lime, yield again colorless oils, the former *citrylene*, the latter *citrene* (or *citronyl*) having a lemon-like odor. Oil of lemon yields with 7 parts of alcohol, specific gravity .830, a turbid solution.

Composition.—Aside from a small quantity of an oxygenated compound, oil of lemon consists of two hydrocarbons having the general formula $C_{10}H_{16}$.

Adulterations with the volatile oils of other fruits of the genus Citrus are very difficult to detect; odor and taste must be chiefly relied on.

Off. Prep.—Linimentum potassii iodidi cum sapone, *Br.;* Spiritus ammoniæ aromat., *U. S.*, *Br.;* Syrupus acidi citrici, *U. S.*

Medical Uses.—Oil of lemons is used almost exclusively as a flavoring agent and as a perfume.

OLEUM LINI, *U. S.*, *Br.*—FLAXSEED OIL.

Linseed oil, E.; *Huile de lin*, Fr.; *Leinöl*, *Leinsamenöl*, G.

Preparation.—This oil is made on the large scale by thoroughly drying the seed with the aid of heat, crushing, and forcibly expressing it. The yield by cold pressure is 10 to 20 per cent., by hot pressure 25 to 28 per cent. It is largely manufactured in this country; in 1867, over 3,200,000 gallons were imported into the United States, but the quantity decreased to 963 gallons in 1877. The importation of flaxseed amounted, in the former year, to 1,769,192 bushels, and in the latter to nearly 85,000,000 pounds.

Properties.—Expressed in the cold, linseed oil is limpid, neutral to test-paper, yellowish, and of a bland, not unpleasant taste. As usually met with, it is somewhat thicker, brownish, has more odor, and a somewhat acrid taste. Its specific gravity is usually .934, but may vary between .928 and .953. It does not solidify at —10° C. (+14° F.), imparts a yellow color to alcohol on being agitated with it, and yields with alkalies a very soft soap. In contact with fuming nitric acid it ignites, but when agitated with nitric acid, specific gravity 1.33, it turns green, and afterwards brown. Exposed to air, it gradually solidifies, and in the crude state, when mixed with mucilaginous matters, it quickly turns rancid and acquires an acid reaction; to obviate this change, the seed before expression is completely deprived of water.

Composition.—According to Mulder (1865), linseed oil is a mixture of about 80 per cent. of *linolein*, with palmitin, myristin, and some elain, all being glycerides. *Linoleic acid* has the formula $C_{16}H_{28}O_4$, and is a colorless acid liquid, readily soluble in alcohol and ether, and on exposure to air is converted into the hydrate of *oxylinoleic acid*, which, in its pure state, is colorless and has the composition $C_{16}H_{26}O_5$, and on continued exposure, more rapidly if frequently moistened with ether, is transformed into *linoxyn*, $C_{32}H_{54}O_{11}$. This latter compound is insoluble in ether, and is produced in a few days on the exposure of boiled linseed oil.

OLEUM LINI SULPHURATUM, *P. G.*, s. *Balsamum sulphuris.*—Six parts of Linseed Oil are intimately mixed in an iron vessel with one part of Sublimed Sulphur, and the mixture boiled over a slow fire in an iron vessel with constant stirring, until the whole has united into a homogeneous mass. *P. G.* The mixture has about the consistence of a thick syrup, and is of a dark red-brown color.

Off. Prep.—Ceratum resinæ comp., Linim. calcis, *U. S.*

Medical Uses.—Flaxseed oil is laxative in the *dose* of one or two ounces. It has been recommended to be given in this manner as a remedy for *hemorrhoids*. Only cold-pressed oil should be used internally. Its most important application is to the treatment of *burns*, when mixed with an equal quantity of lime-water. The same mixture (Linimentum calcis) is also applied with advantage in *impetigo*.

OLEUM MENTHÆ PIPERITÆ, *U. S.*, *Br.*—OIL OF PEPPERMINT.

Essence de menthe poivrée, Fr.; *Pfefferminzöl*, G.

Preparation.—The volatile oil is obtained from the fresh herb of Mentha piperita, *Lin.*, by distilling it with water. For medicinal purposes an oil is preferable which has been rectified by steam distillation. It is largely produced in Michigan, New York, and other States of the Union, and to some extent is exported to Europe, while, on the other hand, some European rectified oil of peppermint is imported into the United States. In Great Britain the yield is stated to be from 8 to 12 pounds of oil per acre (Pharmacographia); in the United States it is said to be sometimes as high as 20 pounds (Stearns, 1858).

Properties.—Oil of peppermint is a colorless, or more frequently yellowish or greenish liquid, which, on exposure, becomes brownish and viscid. Its specific gravity is usually near .90, but varies between .84 and .94. It commences to boil near 190° C. (374° F.), and, at a low temperature, sometimes deposits crystals of menthol. It has a peculiar pungent odor, and a hot, somewhat camphoraceous, and, when old, also bitterish taste, followed by a sensation of cold. It dissolves clear in from 1 to 3 parts of 80 per cent. alcohol, the solution usually becoming opalescent with more alcohol, and depositing slowly a minute white precipitate. It is neutral to test-paper when fresh, and turns polarized light to the left. In its action towards reagents it shows very considerable differences. Jehn (1873) observed that chloral hydrate produces with this oil a rose and cherry-red color; and Dragendorff (1875) proved that this reaction is occasioned by some unknown constituent of impure chloral hydrate, and becomes less distinct the purer the reagent is. Strong nitric acid colors it purplish to brown; but when from 50 to 70 drops of the oil are mixed with 1 drop of nitric acid, specific gravity 1.2, the mixture is gradually changed from yellowish to brownish, and finally to a permanent violet, blue, or greenish-blue when viewed in transmitted light, while in reflected light the mixture is of a red-copper color and opaque; the reaction, which is not prevented by oil of turpentine, may be hastened by warming the mixture or by decreasing the oil (Flückiger, 1871). Picric acid dissolves in oil of peppermint, with a yellow color, gradually, or, when slightly heated, more rapidly, changing to green; in presence of water and air a reddish-yellow is afterwards produced (Frebault, 1874). Iodine does not act energetically with the oil, but dissolves and renders it thicker. With ethereal or chloroformic solution of bromine a rose-red or violet color is produced, changing gradually to a dirty-pink or purplish color. In consequence of insufficient weeding of the mint fields, American oil of peppermint is not unfrequently mixed with oil of erigeron (see page 972), acquires a rank "weedy" smell, and seems to be disposed to resinify more rapidly.

Composition.—Oil of peppermint owes its peculiar odor to *menthol* (mint camphor, mint stearopten), $C_{10}H_{20}O$, which is chiefly contained in the last portions obtained on subjecting the oil to fractional distillation. It forms colorless prisms which fuse at about 35° C. (95° F.), and boil near 210° C. (410° F.). Distilled with phosphoric anhydrid it yields *menthene*, $C_{10}H_{18}$, which is a colorless liquid of an agreeable odor.

Adulterations.—Besides oil of erigeron, alcohol, castor oil, and oil of turpentine have been employed for the purpose; the presence of the last two bodies renders the oil not readily soluble in 80 per cent. alcohol, and the last one mentioned causes it to be acted on with more violence by iodine. Menthol is sometimes met with in commerce as *Chinese oil of peppermint*, and is obtained in China from a variety of either *M. piperita* or *M. arvensis;* on one occasion it was largely adulterated with magnesium sulphate.

Off. Prep.—Aqua menthæ piperitæ, *U. S.;* Essentia menthæ piper., *Br.;* Pilul. rhei comp., Spiritus menthæ piper., *U. S.*, *Br.;* Trochisci menthæ piper., *U. S.*

Medical Action and Uses.—Elsewhere (see Mentha piperita) are described the carminative and anodyne virtues of peppermint, which belong to all its preparations, and especially to its essence (*Spiritus menthæ piperitæ*), which is merely an alcoholic solution of the oil of peppermint. The latter appears to possess in a remarkable degree the analgesic properties of its class. Anciently, peppermint was employed by the Romans as an application to the temples for the relief of headache; and within a few years it became known that the oil was used by the Chinese for a similar purpose. In imitation of their practice, it has been a good deal employed as a local anodyne in *neuralgic headache*, applied over the supraorbital, the temporal, or other nerve in which the pain is most severe. A small wad of compressed cotton saturated with the oil should be laid upon the painful spot, covered with a piece of sheet caoutchouc, and bound firmly in its place. Merely painting the skin with the oil by means of a brush or a tuft of cotton will sometimes answer the purpose. In local *rheumatic* affections the latter method is often very efficient. In *dental caries* this oil is quite as efficient in relieving pain as oil of cloves, and more permanent in its effects than chloroform. For internal use, oil of peppermint may be prescribed in *doses* of from one to three drops; but the officinal *spirit* is to be preferred.

OLEUM MENTHÆ VIRIDIS, *U. S.*, *Br.*—OIL OF SPEARMINT.

Essence de menthe verte, Fr.; *Römisch-Minzöl*, G.

Preparation.—This volatile oil is distilled in the United States and Great Britain from fresh spearmint; the yield is about $\frac{1}{4}$ to $\frac{1}{2}$ per cent.

Properties.—It resembles oil of peppermint in color, specific gravity, changes produced by exposure, and behavior to iodine and to polarized light; but differs from it in odor and the slight cooling taste. We have noticed that fresh oil of spearmint usually dissolves clear in all proportions, while old oil yields a turbid solution with more than 3 parts of 80 per cent. alcohol. Its boiling point, according to Kane, is 160° C. (320° F.).

Composition.—Gladstone (1863) separated from the oil a hydrocarbon, $C_{10}H_{16}$, and an oxygenated oil, $C_{10}H_{14}O$, to which the odor is due, and which has the density .9515 and boils at 225° C. (437° F.).

Off. Prep.—Aqua menthæ viridis, *U. S.*, *Br.;* Spiritus menthæ viridis, *U. S.*

Medical Uses.—Oil of spearmint is less used than the oils of peppermint and horsemint. It appears to be less powerful than those oils, and may be prescribed in *doses* of from two to five drops diluted with sweetened water, or in the form of essence of spearmint.

OLEUM MONARDÆ, *U. S.*—OIL OF HORSEMINT.

Essence de menthe à cheval, Fr.; *Pferdeminzöl*, G.

Preparation.—This volatile oil is obtained in the United States from fresh horsemint by distillation with water or steam.

Properties.—It is a yellowish or usually of a reddish or brownish-red color, lighter than water, readily soluble in alcohol, crystallizing below 5° C. (39° F.), and of a peculiar fragrant odor, and pungent taste. Boiled with nitroprusside of copper it becomes colorless, greenish, brown, and finally nearly black. Iodine dissolves quietly, turning the oil bright red, afterwards blackish and pitchy.

Composition.—The elæopten is probably a hydrocarbon, but has not been further examined. The stearopten is *thymol*, $C_{10}H_{14}O$, identical with that obtained from oil of thyme, and from the oil of *Ptychotis ajowan;* it crystallizes in colorless tabular crystals, has a peculiar odor and pungent taste, is neutral to test-paper, and to polarized light, has the spec. grav. 1.028, fuses at or above 45° C. (113° F.), and boils near 230° C. (446° F.). It is soluble in 333 parts of water, and unites with soda to a crystalline compound, $C_{10}H_{13}NaO$; hence it is sometimes called *thymic acid.*

Medical Action and Uses.—The smallest drop of the oil of horsemint diffuses a pungent, aromatic, and persistent heat over the tongue and fauces, and when applied to the skin it excites redness, heat, and, if the application is continued, pain and vesication. It may be used for the same purposes as oil of peppermint, etc., but is more frequently employed with soap-liniment, or camphorated oil, as an embrocation to relieve the pain of *muscular rheumatism, chronic articular rheumatism,* and *neuralgia.* It is also employed in liniments in local *paralysis, flatulent colic, cholera infantum,* and even in *low forms of fever.* For these purposes one part of the oil to three or four of the excipient may be prescribed. In neuralgia it may be applied pure. Internally, the oil may be given in doses of two or three drops properly diluted with sweetened water.

OLEUM MORRHUÆ, *U. S.*, *Br.*—COD-LIVER OIL.

Oleum jecoris aselli, P. G.; *Oleum hepatis morrhuæ.*—*Cod oil*, E.; *Huile de morue, Huile de foie de morue*, Fr.; *Leberthran, Stockfischleberthran*, G.

Origin.—The fixed oil obtained from the liver of Gadus morrhua, and of other species of Gadus; *Class* Pisces; *Ord.* Teleostia; *Fam.* Gadida.

The *common cod*, formerly called *asellus major*, inhabits the Northern Atlantic, and is frequently met with on the North American coast on and near the banks of Newfoundland, where it seems the *hake, G. merluccius, pollack, G. pollachius*, and *haddock, G. æglifinus*, are likewise used to some extent for the same purpose. On the Norwegian coast, according to De Jongh (1843), cod-liver oil is mainly produced from the *dorse, G. callarias,* but also from the coalfish, *G. carbonarius*, and the *pollack.*

Preparation.—On the coast of Norway the carefully cleaned livers are placed in baskets or barrels, exposed to a sunny place, where the oil slowly exudes, and is removed and filtered; or the livers are slowly heated in a steam- or water-bath, or sometimes boiled with water, the oil being skimmed off from the surface (see *Proc. Amer. Phar. Assoc.*, 1876, p. 810). On the coast of North America cod-liver oil is now generally more carefully prepared. The introduction of ice as a means of preserving has developed the business of transporting codfish fresh to the inland cities during the catching season, from December to March; and likewise that of the proper preparation of cod-liver oil from fresh livers on shore by means of gradually applied steam-heat, whereby the oil is separated from the tissues, the watery portion subsiding, the oil being afterwards filtered and kept in dry vessels in a cool place (see *Amer. Journ. Phar.*, 1854, p. 1, and 1870, p. 214; *Proc. Amer. Phar. Assoc.*, 1875, p. 659.)

Properties.—The purest cod-liver oil is of a pale yellow color, and faint acid reaction; but if prepared at a high temperature, or if the livers are allowed to more or less putrefy, it has a more decided reaction and a pale or darker reddish-brown color, the darkest varieties being transparent only in thin layers, and having a repulsive fishy odor, and a bitterish acrid taste. The acridity and fishy smell are less marked in the light brown oil, and still less in the yellow or white oil, which is nearly bland. At 15° C. (59° F.) the spec. grav. of light cod-liver oil is .92 to .925, of the dark colored about .930. Cold alcohol dissolves not over 2.5 per cent. from the yellow, but about 6 per cent. from dark brown cod-liver oil. At a low temperature a granular crystalline deposit is separated, in largest proportion from the darker colored oil. On the addition of sulphuric acid a violet color soon changing to brown-red is produced, due to the presence of biliary compounds; nitric acid colors it purple, afterwards violet and brown.

Composition.—Cod-liver oil has been repeatedly analyzed, and found to be a mixture of several glycerides, the principal one being olein, with variable quantities of stearin and palmitin increasing with the darker color. Hopfer de l'Orme (1837) first proved the presence of iodine, which, according to L. Gmelin (1840), was supposed to be in combination with potassium; however, hot and cold water and alcohol fail to extract it, and the precise form in which iodine is present is still unknown. The same may be said of bromine, phosphorus and sulphur. Chevallier, Donovan, Herberger, Marder, and others did not find iodine in all samples of cod-liver oil; De Jongh determined its amount to vary between .029 in dark, and .040 per cent. in light brown oil; some investigators have found it in the ashes of soap prepared from it, others in the mother-liquor after separating the soap. Winckler's (1852) statement that glycerin could not be obtained from cod-liver oil, which he regarded as an organic whole, containing oxide of propyle, has not been corroborated by other investigators. De Jongh regards the acid reaction of cod-liver oil as being due to butyric and acetic acids, and has recognized the presence in it of several biliary acids and coloring principles, besides *gaduin*, $C_{35}H_{46}O_9$, which is dissolved from the lead soap by ether, and separated with oleic acid by sulphuric acid. By combining with soda, dissolving in alcohol of 30° B., and cooling to the freezing point of water, the soap is deposited, and gaduin may be obtained on the addition of sulphuric acid; it is dark brown, brittle, inodorous, tasteless, soluble with a red color in sulphuric acid, and reprecipitated by water. It is probably a derivative of bile. *Gadic acid* is the name given by Luck (1857) to a deposit obtained from a light brown cod-liver oil; recrystallized from hot alcohol it fused between 63° and 64° C. (145.4° and 147.2° F.).

Adulterations are very difficult to detect, because the colors mentioned above are but slightly modified by the presence of other oils, and the oils obtained from the livers of some other fishes show similar reactions. Some fish oils, however, are but slightly colored by sulphuric acid; others do not become violet at first, but at once turn brown-red or dark brown. Such substitutions may be detected by this test. An adulteration with resin, noticed by Böttger in 1858, may be detected by the solubility of the adulterant in alcohol. In other respects the physical properties, as detailed above, still afford the best criterion of the purity and quality of cod-liver oil.

In France the liver oil of the ray or *common skate* (raie, *Fr.*, Rochen, *G.*), *Raja batis*, Lin., and in Australia *dugong oil*, an oil produced from the fleshy part of *Halicore dugong*, Cuvier, a fish inhabiting the waters of Eastern Australia and the Indian Archipelago, have been used in place of cod-liver oil.

OLEUM MORRHUÆ FERRATUM has been recommended for some years. Bernbeck (1875) published a process of which the following is an outline: A solution of one part of well-dried neutral olive-oil soap in twenty parts of hot water is precipitated by the gradual addition of a similar solution of one part of ferrous sulphate; the precipitated iron soap is rapidly collected on muslin, washed and expressed to remove the water. This cake, though oxidizing superficially, will internally retain its whitish color for a long time. Four parts of this soap are melted and ninety-six parts of previously warmed cod-liver oil are added, and the heat continued for half an hour or more. This oil is of a dark brown color, and contains 1 per cent. of metallic iron, mostly as ferrous oleate.

EXTRACT OF COD-LIVER is the watery liquid obtained from the livers in preparing the oil, and evaporated; it yields 12½ to 15 per cent. of extract, which is said to consist of biliary constituents 60.6, water 21.8, the remainder being various salts. It was at one time (1866) recommended as a substitute for cod-liver oil.

Physiological Action.—When healthy animals eat a certain quantity of cod-liver oil mixed with their ordinary food, it appears to promote their fattening if a moderate proportion is not exceeded. When more is given them the digestion becomes deranged, and their fat acquires a yellow color and a fishy taste. When the oil is rubbed into the shaven skin of dogs the animals appear to be in as good condition as those which had taken the oil internally, and the same evidences of its absorption are found in the bile and in the richness of the chyle in non-nucleated corpuscles. The fattening operation of the oil in man is familiar to every one; in connection with it the blood becomes richer in corpuscular elements, especially of red corpuscles, thereby, in certain cases, producing a morbid excess of nutritive action which sometimes exhibits itself in hemorrhage, and sometimes in local congestions. When it is given in suitable doses and in appropriate cases, it improves the appetite and digestion; but if taken in excess of the powers of assimilation, and too long continued, it impairs the appetite, renders the tongue foul, excites heartburn, rancid eructations, and even vomiting and diarrhœa, while itching of the skin and a papular eruption are produced, and the perspiration exhales a fishy smell.

Cod-liver oil is essentially a fat-producing agent, and thereby it retards that waste of nitrogenous tissues which is a charateristic of the diseases in which it is most serviceable. In this connection it should be borne in mind that among the various agents vaunted from time to time as remedies for consumption, the most efficient have been oils and fats, *e. g.*, asses' milk, cream, butter, fat pork, buffalo marrow, etc. But cod-liver oil has the advantage over all of these articles that it excels them in digestibility. On what the latter quality depends is not fully determined, but the most plausible opinion is that it is due to the portion of biliary matter which the oil holds in solution. It has been shown experimentally that different oils vary extremely in their diffusibility through membranes, and that cod-liver oil possesses six or eight times more of it than other oils, vegetable or animal. Such appears to be the simple fact, but the explanation of it is not easy. It has been ascribed to the presence in the oil of a certain proportion of bile, and it is asserted that when this bile is removed the oil loses its diffusibility in the same proportion. But on the other hand it is alleged that the process employed to remove the bile does not really do so, but eliminates certain other constituents of the oil. However this may be, no more satisfactory theory has been proposed than that which assigns the peculiar digestibility of the oil to the presence in it of biliary matter. And this view is corroborated by the experiment in which an animal with a biliary fistula became more and more emaciated as long as it used only its ordinary food, but regained flesh and strength when a due proportion of cod-liver oil was added.

Medical Uses.—From time immemorial cod-liver oil was used as a popular remedy for chronic gout and rheumatism, rickets, and scrofula, in Great Britain and the countries bordering on the German Ocean, but it was not until about 1841 that it became generally known and used as a remedy for pulmonary consumption. The enthusiasm which inevitably attends the introduction of a new medicine of real efficacy, exaggerated the benefits conferred by cod-liver oil in these several diseases, but time and well-considered experience have nevertheless proved it to be a valuable remedy. Its curative powers in *chronic rheumatism* have been strikingly shown in cases of that disease prolonged by a cachectic state of the system, cases in which the muscles grow rigid, and the joints stiff, and when to the debilitating influence of these infirmities is added the operation of dampness, crowding, bad ventilation, and coarse and insufficient food, especially in persons of an originally scrofulous constitution. In regard to *scrofula* itself, the medicine is singularly efficacious when the disease affects the internal lymphatic glands and the bones, and under the bad hygienic conditions enumerated above. Yet it is by no means to be depended upon in cases of supposed mesenteric disease; not only because the enlargement of the abdomen which is thought to indicate its existence in children, is commonly a result of splenic or hepatic disorder, but, still more, because true *tabes mesenterica* is most apt to be associated with incurable tuberculosis of the intestines. It is of little use in scrofulous enlargement of the parotid, thyroid, and submaxillary glands, or of the glands of the neck, axillæ, and groins; but its efficacy is seen in the cure of the ulcers left after the discharge of softened scrofulous matter from these parts. Its utility in *scrofulous ophthalmia* is far from being established. At least one-half of the cases receive no benefit from it. It is a more valuable remedy in all forms of idiopathic *strumous caries*, especially when it affects the epiphyses of the long bones; and is still more evidently beneficial in *rachitis*. In the treatment of *white swelling* and other forms of *chronic arthritis*, and of *fistulæ* and *abscesses* in the neighborhood of joints, its powers are sometimes signally displayed. The various diseases of the skin to which scrofulous persons are peculiarly liable are often most favorably influenced by this medicine. Among these *lupus vulgaris* is reputed to have been cured by it more frequently than by any other internal remedy; while some high authorities declare that no cure of existing lupus ever results directly from any kind of internal treatment whatever. It is true, also, that even when given for this disease it is generally associated with other and active medicines. In other scrofulous diseases of the skin, and especially of the scalp, this oil appears to have been used with success both internally and topically. Such diseases are *impetigo*, *chronic eczema*, *psoriasis*, and *favus*. Even *ichthyosis* is said to have been cured by similar means.

The great success which cod-liver oil at one time was believed to have gained as a cure for *pulmonary consumption* has tended more than any other cause to maintain the reputation of the medicine. It is now determined that it exerts little if any direct influence upon the structural elements of that disease, and that it can be said to cure only those rare cases in which other and especially hygienic methods have also restored consumptive patients to apparently good health. Such are the cases in which the patient is of a sluggish, lymphatic temperament, and in which the tubercular deposit is strictly limited to a small portion only of one lung. The efficiency of the medicine is much more notable when a cavity is already formed than when the deposit is in a crude state. It plainly acts by maintaining the general health of the system, while the local disease undergoes retrogression; for it constantly happens that although the latter process fails to occur, but on the contrary the destruction of the lung advances, yet the patient for a time gains weight and strength. In the more favorable examples the symptoms which depend upon the local lesion are mitigated and even suspended, such as fever, sweating, cough, and expectoration. Yet, in proportion as these symptoms prevail, the oil fails to do good, or is not tolerated. Although cod-liver oil is no longer claimed to be a cure for consumption, it still remains incomparably the most efficient medicine in prolonging the lives of the victims of this disease, and enabling them to take advantage of the hygienic measures upon which the main reliance must be placed. *Chronic bronchitis*, which is so apt to be mistaken for tubercular phthisis, is often signally benefited by this medicine, and by the same mode of action. A like remark is applicable to numerous diseases of the *nervous system* due to, or maintained by, an exhausted condition of its functions.

In all diseases its use is contraindicated when it cannot be retained by the stomach; when it is not well digested, but causes eructation, heartburn, diarrhœa, etc.; and when fever is present.

Administration.—The average *dose* of cod-liver oil is a tablespoonful three times a day, an hour or two after meals. It is better to begin with half of this quantity. Various means have been employed to disguise the taste and smell of the oil and render it acceptable to the stomach. These means are generally needless among children, who often become fond of the medicine, and among persons whose taste is not fastidious. The use of ether, naphtha, peppermint, and similar agents is objectionable, since they become volatilized in the stomach, and renew the taste of the oil by eructation. Less apt to produce this effect is alcohol in the form of some distilled spirit, with which the mouth should first be washed, after which the oil floating upon another portion of the liquor may be rapidly swallowed. Malt liquor which froths readily is an excellent article for enveloping the oil and concealing its taste. Floated on iron-rust water, with some of which the mouth and fauces have just been washed, is another available means of effecting the same purpose. But the best of these is chewing a small fragment of smoked herring. When the stomach tends to reject the oil, this effect can sometimes be prevented by preceding each dose by one of a solution of cyanide of potassium, containing not more than one-eighth of a grain of the cyanide. But the possible dangers of the misuse of this solution forbid its ordinary employment. It is better, as well as safer, to swallow a tablespoonful of lime-water, or five or more grains of subnitrate or subcarbonate of bismuth, a few minutes before the oil is taken. The oil has sometimes been mixed with arrowroot, or with spermaceti, forming a bolus which may be taken inclosed in a wafer.

OLEUM MYRISTICÆ, *U. S.*, *Br.*—OIL OF NUTMEG.

Oleum nucistæ æthereum.—*Volatile oil of nutmeg*, E.; *Essence de muscades*, Fr.; *Ætherisches Muskatöl*, G.

Preparation.—The volatile oil is obtained by distilling ground nutmegs by the aid of steam. The yield is between 2 and 3 per cent., but selected nutmegs have yielded 6 per cent. Cloëz (1864) suggests exhaustion with carbon bisulphide and distilling the extract by means of steam.

Properties.—The oil is colorless or pale yellowish, limpid, of specific gravity .92 to .95, of an agreeable aromatic odor, a warm somewhat camphoraceous taste, and dextrogyre to polarized light. It is readily soluble in alcohol, commences to boil at 160° C. (320° F.), fulminates when brought into contact with iodine, is energetically acted on by nitric acid, becomes dark-red with Fröhde's reagent, and violet by muriatic acid (Dragendorff, 1877).

Composition.—The most volatile portion, after treatment with sodium, was found by Cloëz to be a left rotating hydrocarbon, $C_{10}H_{16}$, having the odor of nutmeg and of lemon, and boiling at 165° C. (329° F.). It is the *myristicene* of Gladstone (1872), who named the oxygenated portion *myristicol*, $C_{10}H_{14}O$; this is dextrogyre, boils at 224° C. (435° F.), and does not, like menthol and carvol, yield a crystalline compound with H_2S. The *nutmeg camphor* of John (1821), or *myristicin* of Gmelin, which separates sometimes on standing, was ascertained by Flückiger (1874) to be myristic acid. (See below.)

Off. Prep.—Pil. aloes socotr., *Br.*; Spirit. ammon. aromat., *U. S.*, *Br.*; Spir. myristicæ, *Br.*

Medical Uses.—Oil of nutmeg is seldom used in medicine; it may be employed for the same purposes as nutmeg, in *doses* of two or three drops.

OLEUM MYRISTICÆ EXPRESSUM, *Br.*—EXPRESSED OIL OF NUTMEG.

Oleum myristicæ, P. G.; *Oleum nucistæ expressum, Adeps (vel Butyrum) nucistæ.*—*Nutmeg butter*, E.; *Beurre de muscade*, Fr.; *Muskatnussöl, Muskatbutter*, G.

Preparation.—This fixed oil is obtained in the East Indies by beating nutmegs into a paste, which is expressed between heated plates. The yield is about 28 per cent., and the annual importation into the United States between 200 and 300 pounds. It is incorrectly called *oil of mace.*

Properties.—It is found in commerce in the shape of blocks, about two and a half inches thick and ten inches long, and is wrapped in palm leaves. It is solid and firm, unctuous to the touch, of a mottled appearance, orange and brown in color, of specific gravity .995, and has the fragrance and aromatic but bland taste of nutmegs. It melts at about 45° C. (113° F.), and is soluble in two parts of warm ether and four parts of boiling strong alcohol. (Lecanu.)

Constituents.—Cold alcohol dissolves about 6 per cent. of volatile oil (see p. 983) and 37 per cent. of fat, accompanied by brown-yellow coloring matter, which has not been further examined. The remaining white fat is *myristin*, $C_3H_5O_3.3C_{14}H_{27}O_2$, which crystallizes from hot alcohol or ether, and fuses at 31° C. (87.8° F.). Heintz (1854) found the melting point of *myristic acid* at 53.8° C. (128.8° F.). The myristicin of *otoba butter*, from Myristica otoba, of New Grenada, melts at 46° C. (114.8° F.), according to Uricoechea (1854).

Adulterations and Substitutions.—The expressed fats of *Myristica fatua* and *otoba* resemble the officinal article, but have not the fragrance of the latter. Artificial mixtures made from animal fats are not soluble in the same amount of hot alcohol.

CERATUM MYRISTICÆ, P. G., also known as *Balsamum nucistæ*, is made by melting together yellow wax one part, olive oil two parts, and expressed oil of nutmeg six parts, pouring into paper capsules, and cutting into square cakes.

Off. Prep.—Emplast. calefaciens, Empl. picis, *Br.*

Medical Uses.—Oil of nutmeg is sometimes used for the friction of rheumatic parts, but chiefly as a bland and smooth fatty substance that does not easily grow rancid, and is therefore suitable as an excipient of more active topical medicines.

OLEUM OLIVÆ, *U. S.*, *Br.*—OLIVE OIL.

Oleum olivarum, P. G.—*Sweet oil*, E.; *Huile d'olive*, Fr.; *Olivenöl*, G.

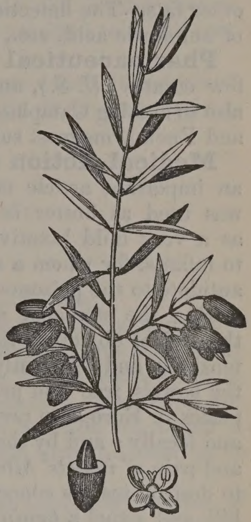
The fixed oil obtained from the fruit of Olea europæa, *Lin.* Woodville, Med. Bot. t. 98; Bentley and Trimen, Med. Plants, 172.

Nat. Ord.—Oleaceæ.

Origin.—In its wild state, the olive is almost shrubby, much branched and thorny; but under cultivation it is a medium-sized tree, 30 or 40 feet high. It is indigenous to Western Asia, particularly Syria, and has been cultivated for a long time in the countries bordering on the Mediterranean. It has been introduced into the Southern United States, California, and several South American and other countries. The tree has evergreen, opposite, shortly petiolate leaves, which are about two inches long, lanceolate, acute at both ends, entire and revolute on the margin, and densely scaly, silvery gray, brownish- or glaucous-green beneath. The numerous small white flowers are in axillary racemes, diandrous, have a two-celled and four-ovuled superior embryo, and produce a purplish-black ovate drupe about an inch long, with a greenish firm sarcocarp, and an obliquely oblong keeled putamen, containing a single albuminous seed.

The leaves and bark have been employed in France as a febrifuge. De Luca (1861, etc.) found the leaves and green fruit to contain mannite, which diminishes in the latter as the fruit ripens, and disappears entirely when it becomes perfectly ripe. It contains then the largest amount of oil, equal in weight to nearly 70 per cent. of the sarcocarp.

Fig. 121.



Olea europæa, *Lin.*

Preparation.—The finest quality of olive oil is obtained by crushing the recently collected olives in a suitable mill to a pulpy mass, and subjecting this to moderate pressure, the oil, called *virgin oil*, being collected in cisterns containing water, from the surface of which it is subsequently skimmed. The press cakes are afterwards thoroughly mixed with boiling water and the marc again expressed, using an increased pressure, whereby a second quality of oil is obtained. A larger amount of oil, but much inferior in quality, is yielded by expressing olives which have been kept in heaps and undergone a kind of fermentation; this oil is known in France as *huile fermentée;* and a still inferior oil is prepared by again mixing the residue with boiling water and expressing.

Olive oil enters commerce put up in bottles of various sizes, also in stone jugs and in barrels. The importation of olive oil into the United States amounts annually to over 300,000 gallons, fully three-fifths of which quantity is *salad oil.*

Properties.—Olive oil is a pale yellow or greenish-yellow oily liquid, having a slight agreeable odor and a bland taste, leaving, even in its freshest condition, a slight sense of acridity (*Pharmacographia*), which is somewhat increased on keeping. Its specific gravity at 15° C. (59° F.) is 0.9178. At and below 10° C. (50° F.), olive oil separates white crystalline granules, and congeals completely at or below the freezing point of water, yielding, however, by strong pressure from 67 to 72 per cent. of liquid oil, which remains fluid at —10° C. (14° F.), and is nearly pure *olein.* The solid portion fuses between 20° C. (68° F.) (Pelouze and Boudet), and 28° C. (82.4° F.) (Lecanu), and is easily soluble in ether. Olive oil is sparingly soluble in alcohol, freely soluble in ether, does not readily become rancid, and belongs to the non-drying oils. When heated to 120° C. (248° F.), it becomes lighter, and at 220° C. (428° F.), nearly colorless and, at the same time, rancid; it commences to boil at about 315° C. (600° F.).

Inferior qualities of olive oil are of a deeper hue, have a more decidedly acrid after-taste, and turn rancid on exposure.

Composition.—The liquid portion is *triolein* (olein), $C_3H_5O_3.3C_{18}H_{33}O$, and is identical with the liquid portion of most non-drying fats, as far as they have been examined. The solid part was called *margarin* by Chevreul, which was proven by Heintz (1852) to be a mixture containing chiefly *palmitin.* Palmitic acid, $C_{16}H_{32}O_2$, was obtained from olive oil by Collett (1854), and also by Heintz and Krug (1857), who likewise isolated *arachic (butinic) acid*, $C_{20}H_{40}O_2$, and probably stearic acid. On saponification, glycerin is obtained. The fats composing olive oil are, therefore, triolein, tripalmitin, triarachin, and possibly tristearin. Beneke (1862) announced also the presence of a small quantity of *cholesterin*, $C_{26}H_{44}O$, which is soluble in alcohol (see page 608).

Adulterations.—Olive oil is frequently adulterated with other bland oils, some of which are occasionally even substituted for it. The determination of its purity has been the subject of much research, but from the chemical identity of the constituent compounds of many oils, and the natural variation of their relative proportions in the same fat, it is evidently attended with many difficulties. A higher specific gravity than given above points to an admixture of other fats. The detection of drying in non-drying oils, and the testing by means of sulphuric acid, etc., have been described above (see page 950).

Pharmaceutical Uses.—Olive oil is employed in the preparation of a few cerates (*U. S.*), and ointments (*Br.*), and of most liniments and plasters; also in making Cataplasma lini, *Br.;* Charta cantharidis (epispastica), *U. S.*, *Br.;* and Enema magnes. sulphat., *Br.*

Medical Action and Uses.—From time immemorial olive oil formed an important article of food in countries where the olive tree flourishes, and was used as butter is elsewhere. In the dose of one or two ounces it acts as a very mild laxative, but it is seldom administered for this purpose except to infants, for whom a sufficient dose is a teaspoonful. It has been used as an antidote to the poisonous effects of *cantharides*, and is probably efficient in protecting the stomach, as well as by occasioning vomiting, notwithstanding the theoretical objection that cantharidin is soluble in sweet oil. It has been extensively and efficiently employed by workmen in white-lead factories to keep the bowels free and prevent the absorption of the metal. It is used in some places in Europe to prevent the poisonous effects of *vipers' bites*, both internally and locally; and by the latter method it is familiarly applied to allay the swelling and pain of *insects' bites and stings.* It is often poured into the *auditory canal* to destroy insects concealed therein; and large doses of it have been known to kill and expel a *tænia.* Externally it is a convenient and efficient protective and lenitive for superficial *wounds*, *excoriations*, *burns*, *bruises*, and *sprains.* In the two last-mentioned injuries it should be applied warm, and in them also it affords a convenient vehicle for the application of camphor, morphia, and various other anodynes or stimulants. The same is true in regard to several local inflammations, especially *earache.* With lime-water it forms the liniment so useful in burns (*Linimentum calcis*). Anciently the custom of anointing the body with oil was practised, as it still is in Oriental countries, after warm bathing, and also as a protective against the plague. It is now occasionally used to moderate excessive *sweating.* Warm oil is a soothing and efficient application, when made with appropriate pressure or friction, in lessening the pain and swelling of enlarged glands, particularly those which are actively engorged, as the *mammæ* during pregnancy and after parturition. It is sometimes injected into the rectum in *dysentery*, and to destroy rectal *ascarides* (oxyures); and it is habitually employed to facilitate the introduction of *sounds*, *catheters*, *bougies*, *specula*, *pessaries*, etc., into the natural cavities of the body. It was an old custom to dip cutting surgical instruments in oil before incising the flesh.

The *dose* of olive oil as a laxative is one or two fluidounces for adults, and for infants one or two fluidrachms.

OLEUM ORIGANI, *U. S.*—OIL OF ORIGANUM.

Essence d'origan, Fr.; *Dostenöl*, G.

Preparation.—This volatile oil is obtained from the fresh herb of Origanum vulgare, *Lin.*, by distilling it with water. Raybaud obtained only 0.024 to 0.03 per cent. from the fresh plant, and Redtel 2 per cent. from the recently dried herb. Red oil of thyme (see page 1002) is often sold in its place.

Properties.—It is pale-yellow and limpid, becoming thicker and brown-yellow on exposure, has a strong aromatic odor and a warm, pungent, and slightly bitter taste. Its specific gravity varies between 0.87 and 0.91. It yields a turbid solution with 12 parts of alcohol specific gravity 0.85, fulminates when brought into contact with powdered iodine, acquires with sulphuric acid a dark blood-red color, and a deep-brown one with potassium bichromate and sulphuric acid (Zeller).

Composition.—Oil of origanum consists of a liquid and a solid portion, which have not been fully investigated. Kane (1838) ascribed to it the composition $(C_{10}H_{16})_5O$.

Medical Action and Uses.—Like the plant from which it is derived, this oil is stimulant and carminative, and is applied locally as an anæsthetic to relieve the pain of *carious teeth*, *neuralgia*, etc.

OLEUM PALMÆ.—PALM OIL.

Huile de palme, Fr.; *Palmöl*, *Palmbutter*, G.

From the fruit of Elais guineensis, *Jacq.* *Nat. Ord.*—Palmæ.

Origin.—The oil palm is a tall tree indigenous to Western Africa, and introduced into other tropical countries. It has large pinnate leaves with spiny petioles and long narrow linear leaflets. The fruit is a yellow mottled drupe, about an inch long, and contains a leathery very oily sarcocarp, from which the fat is obtained by pressure. The kernel yields likewise a bland oil which is white. Nearly 917,000 gallons of palm oil were imported into this country in the year 1876–1877.

Properties.—Palm oil is solid at the common temperature, butyraceous, of a reddish-yellow color, and when fresh of an agreeable violet-like odor, and fuses at 27° C. (80.6° F.). On keeping, it acquires a rancid odor, a portion of the fat being decomposed into free acids and glycerin, the fusing point rising at the same time. When rapidly heated to 240° C. (464° F.) it is bleached. It is partly soluble in alcohol, but entirely so in ether.

Composition.—It consists chiefly of tripalmitin and triolein, and contains a peculiar ferment, inducing its decomposition. It is largely used in the preparation of soap.

Medical Action and Uses.—Palm oil has hardly any peculiar virtues to distinguish it from other vegetable fats, except that it is less drying and more emollient. It is supposed to be especially adapted for bathing *bruises* and *sprains*. Its agreeable odor recommends it.

OLEUM PHOSPHORATUM, *Br. Add.*—PHOSPHORATED OIL.

Huile phosphorée, *Liniment phosphoré*, Fr.; *Phosphorhaltiges Oel*, G.

Preparation.—Take of Phosphorus, Oil of Almonds, each a sufficiency. Heat the oil in a porcelain dish to 300° F., and keep it at this temperature for about fifteen minutes; then let it cool, and filter it through paper. Put four fluidounces of this oil into a stoppered bottle, capable of holding four and a half fluidounces, and add to it twelve grains of phosphorus. Immerse the bottle in hot water until the oil has acquired the temperature of 180° F., removing the stopper two or three times to allow the escape of extended air; then shake the oil and phosphorus together until the latter is entirely dissolved. *Br.* By heating the oil as directed, air and moisture which may be contained in it are expelled. The phosphorus, before it is introduced, should be rapidly dried between bibulous paper. The finished preparation contains three-quarter per cent. of phosphorus. The solubility of phosphorus in fixed oils is generally stated to be 1 in 100.

Properties.—Phosphorated oil is a clear yellowish oil, having the odor of phosphorus. In contact with air, it produces white fumes, and is phosphorescent in the dark. Since the phosphorus is readily oxidized, the oil should be kept in well filled vials, as directed by the French Codex, or prepared extemporaneously according to the German Pharmacopœia. Both these authorities order saturated solutions of phosphorus in almond oil.

Medical Action and Uses.—In so far as phosphorus is useful as a medicine, it may be conveniently administered in this oil, which contains three grains of phosphorus in each fluidounce, and may be prescribed in the *dose* of from five to ten minims. It is very convenient as an addition to cod-liver oil in cases of *scrofula*, *chronic phthisis*, *paralysis* without central lesion of substance, sexual *debility*, and diseases referred to under Phosphorus.

OLEUM PIMENTÆ, *U. S.*, *Br.*—OIL OF PIMENTO.

Essence de piment de la Jamaïque, Fr.; *Nelkenpfefferöl*, G.

Preparation.—The volatile oil is obtained from the ground fruit of Eugenia pimenta, *D. C.*, by distilling it with water. The average yield appears to be about four per cent., but is often much lower. Bonastre (1827) states that the seeds contain five per cent., and the remaining part of the fruit ten per cent. of volatile oil.

Properties.—Oil of pimento is colorless, or pale yellow, becoming darker by age. Gladstone (1872) gives its specific gravity as 1.0374 at 10° C. (50° F.). In taste and in behavior to solvents and chemicals, it closely resembles oil of cloves; its odor, however, is more pleasant.

Composition.—Gladstone has corroborated the observation of Bonastre concerning the presence of eugenic acid, and the close similarity of this oil to oil of cloves.

Medical Uses.—The oil of pimento is used for the same purposes, local and general, as other aromatic stimulants. The *dose* is from two to six drops.

OLEUM RICINI, *U. S.*, *Br.*—CASTOR OIL.

Oleum Palmæ Christi.—*Huile de ricin*, Fr.; *Ricinusöl*, G.

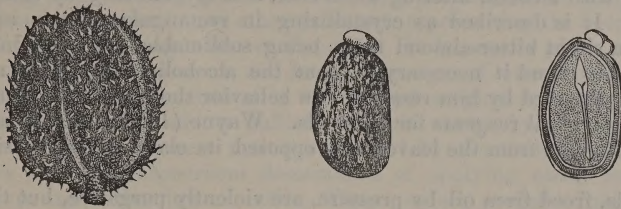
The fixed oil obtained from the seeds of Ricinus communis, *Lin.* Bot. Mag., plate 2209; Bentley and Trimen, Med. Plants, 237.

Nat. Ord.—Euphorbiaceæ.

Origin.—The castor oil plant appears to be indigenous to Southern Asia, but was early introduced into all tropical and subtropical countries, in many of which it has become naturalized, attaining in the tropics the size of a tree thirty to forty feet high. It is often cultivated in temperate countries for ornament and other purposes, remaining an annual, varying in size from four to fourteen feet. Numerous varieties are now known, differing from one another in size and color of the stem and foliage, as well as of the fruit and seeds. The leaves are alternate, peltate, palmately seven- or nine-lobed; the inflorescence is paniculately spicate, terminal, finally axillary; the flowers are monœcious, apetalous, the staminate ones at the base of the panicle. The fruit is a subglobular, somewhat triangular and grooved tricoccous capsule, which is sometimes nearly smooth, but mostly spinescent; each cell incloses a single oval, somewhat flattened seed, which is smooth, shining, of a gray color variegated with yellowish, brown, or reddish spots and lines, with a slightly raised raphe along the flattish side, and a prominent caruncle near one end. The embryo is straight, has foliaceous heart-shaped cotyledons, and is imbedded in an oily albumen, having a bland and scarcely acrid taste.

Preparation.—Nearly all the castor oil which is at the present time consumed in the United States is manufactured from seeds grown in the country. While in the year ending June 30, 1867, the importation of castor oil was 82,800 gallons, and of the seeds 60,588 bushels, the quantities imported ten years later were 612 gallons and 29,255 pounds respectively. The seeds, after having been crushed and freed from the integuments, or without removing the latter, are kiln-dried and subjected to powerful pressure; the oil thus obtained is heated with water to remove albuminous matters, and when clear, drawn off into barrels or other suitable vessels. More oil, but of inferior quality, is obtained by again expressing the marc, and using a higher temperature and greater power. The older method of obtaining the oil by boiling the seeds with water and skimming it from the surface has probably been abandoned in most countries. L. Boerner (1876) extracted from the presscake with ether fourteen per cent. of oil having a light yellow color, while alcohol dissolved twenty-one per cent. of dark oily matter.

Fig. 122.



Ricinus communis, *Lin.* Fruit, seed, and longitudinal section of seed; natural size.

Purification.—Cold-pressed castor oil is nearly transparent, and requires no further purification. If opaque, the oil is filtered, either through paper or felt, or, as recommended by Pavesi (1857) is previously treated for several days with 1 per cent. of magnesia, and 2.5 per cent. of purified animal charcoal, which treatment renders it nearly colorless and inodorous.

Properties.—Castor oil is viscid, transparent or nearly so, almost colorless or pale greenish-yellow, of a faint, mild odor, and a bland, slightly acrid taste. Its specific gravity is about 0.96. At a low temperature it becomes thicker, and usually deposits white granules of solid fat; near —18° C. (near 0° F.) it congeals to a yellowish mass. It is only partly soluble in petroleum benzin, but soluble in all proportions in absolute alcohol, ether, and glacial acetic acid, and at 15° C. (59° F.) in about 4 parts of alcohol, spec. grav. 0.835. When exposed to the atmosphere in thin layers, it slowly dries to a transparent varnish. Polarized light is by some samples turned to the right, by others to the left. It commences to boil at about 265° C. (509° F.), and yields an oily distillate; at a higher temperature it becomes black. Heated with dilute nitric acid, or with potassium bichromate and sulphuric acid, *œnanthylic acid* $C_7H_{14}O_2$, having an agreeable aromatic odor, is obtained.

Composition. 1. THE OIL.—Castor oil is composed of several fats, the acids of which have been the subject of repeated investigations. The solid, fatty acid is probably identical with, or closely related to, *palmitic acid;* the liquid one has been named *ricinic* or *ricinoleic acid*, $C_{18}H_{34}O_3$, and forms a wine-yellow, inodorous liquid, of a disagreeable acrid taste, solidifying below 0° C. (32° F.) to a granular mass, and under the influence of nitrous acid is converted into *ricinelaidic acid*, which has the same composition, and crystallizes in silky needles. The acrid principle of castor oil has not been isolated.

2. THE SEEDS.—Besides the oil, of which the seeds contain about one-half their weight, a considerable amount of protein compounds, some sugar and mucilage are met with in them. Among the proteids is one which H. Bower (1854) regards as related to *emulsin*, inasmuch as it generates, with amygdalin, the odor of hydrocyanic acid. This observation was confirmed by Boerner (1876). The proteid is obtained by agitating the emulsion of the seeds with ether, and precipitating the aqueous liquid with alcohol.

In 1864, Tuson announced the discovery of an alkaloid *ricinin*, which is isolated by preparing an extract with boiling water, freeing it from the fat, exhausting with alcohol, filtering when cool, and crystallizing by concentrating the liquid. It is described as crystallizing in rectangular prisms and scales, possessing a slight bitter-almond taste, being sublimable, and containing nitrogen. Boerner found it necessary to treat the alcoholic liquid with magnesia; the crystals obtained by him resembled in behavior those of Tuson, but did not react with the usual reagents for alkaloids. Wayne (1874) isolated apparently the same principle from the leaves, and opposed its claim to be considered an alkaloid.

The seeds, freed from oil by pressure, are violently purgative, but the principle to which this action is due has not been isolated. On mixing the marc with water, and allowing the mixture to ferment, Boerner obtained butyric, and probably other volatile acids, but no acetic acid.

Off. Prep.—Collodium cum cantharide, *U. S.;* Collodium flexile, *U. S.*, *Br.;* Liniment. sinapis comp., Pilul. hydrarg. subchloridi comp., *Br.*

Physiological Action.—Castor oil derives its purgative properties chiefly from an acrid principle contained in castor beans, which, when taken designedly or accidentally, have repeatedly occasioned violent pain, vomiting, purging, collapse, and even death, after which evidences of severe inflammation have been found in the mucous membrane of the stomach and intestines. When castor oil was injected into a vein, its taste was presently perceived in the mouth, and there followed nausea, eructation, rigidity of the muscles of the tongue, loss of speech, anxiety, and faintness, with general dulness and depression. At the end of three hours an unsuccessful motion to evacuate the bowels occurred, followed by feverishness, and an indisposition of several weeks' duration. Rubbed upon the skin of the abdomen in young children it has procured one or two loose stools. Taken in medicinal doses it sometimes nauseates, seldom gripes, but is apt to cause a tendency to sleep. The first evacuations which follow are generally liquid, and contain more or less of the oil, either unchanged, or converted into cheesy flakes or a soap-like scum floating on the surface of the dejection. It has long been observed that, when used as an habitual laxative, the dose may be progressively diminished. Indeed, unless this is done, it is very apt to occasion constipation and all its attendant evils. In a case of hydræmia with venous pulsation, castor oil, given by the mouth, did not purge, but exuded through the skin.

Medical Uses.—Castor oil is used as a purgative whenever the intention is simply to overcome *constipation*, or, on the other hand, to cure *diarrhœa* depending upon the presence of irritating substances in the bowel, or upon congestion, irritation, and excessive secretion, produced by cold. In not a few cases, especially of infantile diarrhœa, the intestine is irritated at once by the presence of undigested food and by the vitiated secretions of its lining membrane, the patients are distressed by colic, tenesmus, and frequent stools which are watery, mucous, and bloody in different proportions, the mouth is aphthous, and the anus inflamed. In such cases the first step should be thoroughly to cleanse the intestine by means of castor oil in small and repeated doses, preceded or not by a small dose of calomel or of mercury with chalk. The rest of the treatment may be confided to medicines of a different kind, and to dietetic regimen. This purgative has the advantage over most others of analogous qualities, that it has no tendency to exhaust the strength. Hence it is much used during *pregnancy*, and especially immediately before *labor*. There is a popular notion that it tends to relax the maternal organs. Castor oil has been highly recommended in *colica pictonum*, or Poitou colic, produced by acid drinks containing lead, and in *colica pictorum*, or painter's colic, caused by the habitual absorption of the metal. In the former affection it affords prompt relief; in the latter it has no superiority over other, and especially more active, cathartics. It sometimes suffices to expel *lumbricoid worms*, but cannot be at all depended upon for the removal of *tæniæ*, unless they are previously killed by a proper tæniacide. In the forming stage of *laryngeal* or *bronchial inflammation* a laxative dose of castor oil is far superior to any other evacuant in promoting the bronchial secretion, and thereby tending to hasten the cure. It is usually given after parturition when *milk fever* threatens, and later when signs of *mammary abscess* arise. It is also commonly prescribed after wounds and surgical operations to mitigate *traumatic fever;* it is said to palliate the pain caused by *renal calculi*. The local uses of castor oil were mainly suggested by the custom among African aborigines and their American descendants of applying castor leaves to the mammæ to excite the flow of *milk*. They produce a slight irritation of the skin. A fluid extract prepared from the leaves and applied in the same manner is said to have a like effect; and a decoction has been used for the cure of *amenorrhœa*. The oil enters into numerous liniments, etc., for the cure of *alopecia*. Of these one of the best is composed of suet, ℥ij; castor oil, ʒvj; gallic acid, ʒss. Mix, and scent with essence of vanilla. Castor oil is often prescribed in emulsion with yelk of egg, mucilage, etc., but its activity is thereby diminished. Its taste may be disguised by giving with it an equal quantity of glycerin to which a few drops of oil of cinnamon have been added. It should not be taken in milk, coffee, hot soup, or any other articles of food, lest they become repugnant afterwards. If the mouth and fauces are washed with an alcoholic liquid, or even with glycerin, the oil will not adhere, and, therefore, not excite disgust. Or it may be floated upon fresh orange-juice in a wineglass, and covered with another layer of the juice, and so tossed down the throat without its taste being perceived. Probably the best expedient of all is to envelop the oil with the froth of beer, ale, or porter in a wineglass; it may then be swallowed without even its presence being detected. The average *dose* of castor oil for an adult is from half an ounce to an ounce, taken at once or in several portions, according to the nature of the case. The *dose* for an infant is about a fluidrachm. For an enema one or two fluidounces may be given in half a pint of mucilage or soap and water.

OLEUM ROSÆ, *U. S.*—Oil of Rose.

Oleum rosarum.—Attar, Otto of rose, E.; *Essence de rose*, Fr.; *Rosenöl*, G.

Origin and Production.—Roses are largely cultivated in India and various parts of Northern Africa for the production of rose-water and attar, which, however, are consumed in those countries. Large quantities of rose-water are distilled in Southern France, but little oil is obtained there. Commerce is almost exclusively supplied with oil of rose from the southern slope of the Balkan Mountains in Rumelia, the principal depot, previous to the recent war between Russia and Turkey, having been the town of Kizanlik. The species of rose cultivated in that district, according to Baur (1867), is a variety of Rosa damascena, *Miller*, which grows to the height of over six feet, and is raised in hedge-like rows. The flowers appear in May and June, and are collected before sunrise for distillation on the same day. The still used is made of copper, conical in shape, and has its globular head connected with a straight tin tube, passing through a tub filled with water. The charge for each still is about 10 okes (or 27 pounds) of flowers and 20 okes of river water, and the distillation is completed in two hours. The distillates are again distilled, the first sixth being set aside, to allow the oil to separate, while the remainder, together with the water pressed from the exhausted flowers, is used for fresh roses in place of water. The average annual production of oil of rose is about 4000 pounds, of which quantity over 10,000 ounces are imported into the United States; in the year ending June 30, 1877, the importation amounted to 17,539 ounces.

Properties.—Oil of rose is pale yellow, transparent, solidifies if slowly cooled above 10° C. (50° F.) to a perfectly transparent mass, composed of scale-like crystals, and fuses again at a somewhat higher temperature. Congealing and fusing point vary to some extent; the former is given by Baur at between 11° and 16° C. (51.8° and 60.8° F.), the latter, by Hanbury (1859), as lying between 16.1° and 18.3° C. (61° and 65° F.), and for English oil of roses was found as high as 32.8° C. (91° F.). Zeller observed the fusing point of German oil of rose to be even 37.5° C. (99.5° F.). Oil of rose has the odor of the flowers in a high degree, and when suitably diluted with alcohol is very fragrant. Its taste is sweetish and rather mild.

Composition.—When oil of rose is mixed with about 3 parts of alcohol, and the undissolved portion repeatedly dissolved in a little ether, and reprecipitated by alcohol, it is finally obtained as transparent iridescent inodorous scales, which, according to Blanchet (1833) and Flückiger (1868), have the formula C_nH_{2n}, fuse at 35° C. (95° F.), distil above 280° C. (536° F.) (Blanchet), and require about 500 parts of alcohol for solution (Saussure). This stearopten is present in Turkish oil of rose to the amount of 6 or 7 per cent. (Hanbury), but in much greater proportion in oil obtained from roses grown in other parts of Europe. Flückiger found the stearopten to fuse at 32.5° C. (90.5° F.), to emit vapors at 150° C. (302° F.), and to be decomposed at and above 275° C. (525° F.). The elæopten of oil of rose contains oxygen, but its exact composition has not been ascertained.

Adulterations.—The oil which is mostly employed for adulterating oil of rose is known in commerce as *Turkish oil of geranium*, and was shown by Hanbury (1859) to be entirely different from the volatile oil of pelargonium. It is obtained in India from Andropogon schœnanthus, *Lin.*, known as *roshé* or *rosé oil*, and in English commerce also as *oil of gingergrass;* it is imported into Turkey for the purpose of adulterating oil of rose. The most certain criteria of the purity of the latter are, according to Baur, 1, the odor, by which oil of rosewood, sandal-wood, and others, may be detected; 2, the temperature at which it congeals; and 3, the manner of crystallizing. Pure oil of rose exposed to a temperature of 12.5° C. (54.5° F.) should congeal in a few minutes; the crystals should be transparent, scaly, and float in the liquid, while spermaceti, being heavier, is deposited as a solid crust.

Medical Uses.—It is used in medicine exclusively for perfuming ointments and lotions.

OLEUM ROSMARINI, *U. S.*, *Br.*—OIL OF ROSEMARY.

Oleum anthos.—Essence de romarin, Fr.; *Rosmarinöl*, G.

Preparation.—The volatile oil is obtained from the flowering tops, or, more frequently, the entire plant of Rosmarinus officinalis, *Lin.*, by distilling them with water. Commerce is chiefly supplied with oil of rosemary from Southern France and Italy.

Properties.—Oil of rosemary is a colorless or yellowish limpid liquid, varying in specific gravity between 0.88 and 0.91, has a pungent somewhat camphoraceous odor, boils at 165° C. (329° F.), and is soluble in less than its own weight of 80 per cent. alcohol; old oil requires a larger quantity for solution. Mixed with iodine, it gives off reddish vapors, and strong sulphuric and nitric acid render it thick and brown-red. Fröhde's reagent colors it yellowish-brown. The oil deviates polarized light to the left.

Composition.—The presence of oxygen in oil of rosemary was proven by Saussure (1820). Gladstone (1863) regards it as consisting almost entirely of a hydrocarbon very similar to that contained in the oil of Myrtus communis, *Lin.* Lallemand (1859), however, obtained by fractional distillation a liquid boiling at 200° C. (392° F.), from which a stearopten was obtained having the composition and most of the properties of camphor.

Off. Prep.—Linim. saponis, Spiritus (Tinctura) lavandulæ comp., *U. S.*, *Br.*; Spiritus rosmarini, *Br.*

Medical Action and Uses.—This oil is poisonous to rabbits in the dose of twenty grains. A case is recorded in which, along with oil of wormwood, it caused the death of a child. Internally, it may be employed for the same purposes as other stimulant oils, to relieve *colic*, promote *menstruation*, and allay *nervous disorder* due to debility. In ointments and liniments, it is a useful ingredient for relieving *rheumatic* pains; it promotes the removal of swellings due to *rheumatism*, *sprains*, *bruises*, etc.; and promotes the growth of the hair in *alopecia* following febrile affections. Its vapor cautiously allowed to act on the conjunctiva sometimes improves *vision* impaired by nervous exhaustion. Internally, the *dose* is one or two drops.

OLEUM RUTÆ, *U. S.*, *Br.*—OIL OF RUE.

Essence de rue, Fr.; *Rautenöl*, G.

Preparation.—This volatile oil is distilled with water from the herb of Ruta graveolens, *Lin.* The yield from dry herb is about $\frac{1}{4}$ per cent., from fresh herb $\frac{1}{20}$, and from the seeds 1 per cent. (Zeller.)

Properties.—Oil of rue is a colorless or greenish-yellow liquid having the peculiar odor of the plant and congealing at a low temperature in shining scales. The freezing point varies in different samples, according to Geiss (1861), between —2.5° and —22.5° C. (27.5° and —8.5° F.), that obtained from the seeds congealing first. Iodine dissolves quietly in the oil; sulphuric acid dissolves it with a brown-red color; and sodium bisulphite yields with it a crystalline compound. By the action of nitric acid, *caprinic*, *pelargonic*, *caprylic*, and *œnanthylic acids* are produced, the products varying with the strength of the acid and its prolonged action.

Composition.—Aside from a small quantity of a hydrocarbon, oil of rue consists mainly of an oxygenated portion, which Cahours and Gerhardt (1845) stated to be *caprinic aldehyd*, $C_{11}H_{22}O$. Harbordt (1862) showed that it could not be an aldehyd, and regarded it as *methyl-caprinol*, $C_{10}H_{19}.CH_3.O$, and Strecker as a ketone having the formula $CH_3.CO.C_9H_{19}$. The latter view has been proven to be correct by the simultaneous observations made by Gorup-Besanez, F. Grimm, and A. Giesecke (1870). This *methyl-nonyl ketone*, when pure, is a colorless liquid with a bluish fluorescence, boiling at 225° C. (437° F.), crystallizing in scales near 5° C. (41° F.), and fusing again at 15° C. (59° F.).

Medical Action and Uses.—An experimenter having taken within an hour three doses of oil of rue, of ten minims each, suffered uneasiness in the stomach, oppression and confusion of mind, aching in the loins, an urgent desire to urinate—the urine smelling of the oil—flushes of heat, unsteadiness of gait, a tendency to sleep, and increased frequency, with diminished tension of the pulse. These phenomena are essentially those produced by oil of wormwood and numerous other essential oils, and the therapeutic uses of oil of rue are the same as theirs, viz., in the treatment of *colic*, *amenorrhœa*, *dysmenorrhœa*, *uterine hemorrhage*, and *verminous complaints*. It may be given in *doses* of from one to five drops.

OLEUM SABINÆ, *U. S.*, *Br.*—OIL OF SAVIN.

Essence de sabine, Fr.; *Sadebaumöl*, G.

Preparation.—Oil of savin is obtained by distilling the fresh branches of savin with water. The yield is between 1½ and 2½ per cent.; Voget obtained from the berries nearly 10 per cent. of volatile oil.

Properties.—The crude oil has a yellowish or yellow color, and is obtained colorless on rectification. Its specific gravity is about 0.91, but varies somewhat. It commences to boil near 160° C. (320° F.), and dissolves in absolute alcohol in all proportions, but yields an opalescent solution with 3 parts of 80 per cent. alcohol. Mixed with powdered iodine, a brisk detonation results, and on the addition to the oil of an ethereal solution of bromine, the color of the latter disappears instantly. The oil does not appear to yield a solid compound with hydrochloric acid gas. It rotates polarized light to the right.

Composition.—Dumas (1835) found it to agree with oil of turpentine in elementary composition. Its formula is $C_{10}H_{16}$.

Physiological Action. *On Animals.*—It first excites, perhaps by the stimulus of pain, the movements of the heart and the respiratory muscles, occasions vomiting, sometimes of a bloody liquid, causes bloody urine to be frequently voided, then produces insensibility, paralysis, a rapid pulse, and gradual death; after which the odor of the oil can be detected in the cavities of the body and in the blood and urine. The intestines are congested, and their epithelium exfoliated; the kidneys are greatly congested, and the urinary bladder injected.

On Man.—Applied to the skin, oil of savin does not vesicate nor produce any marked redness. Internally, small and repeated doses produce more or less vascular excitement, with heat of head and flushed face; and larger, but not poisonous doses increase the secretion of urine and cause vesical and rectal irritation, while the odor of the oil exhales from the skin, breath, and urine. In cases of poisoning by this oil, these symptoms occur in an aggravated form, together with violent and continuous vomiting, and in pregnant females it may produce abortion and the death of the mother. The case of an infant is related who died from inhaling the fumes of oil of savin, from a bottle which had been left open near its cradle, after having been used to bathe the child's hip.

Medical Uses.—Oil of savin is an appropriate medicine in all of the cases to which savin itself is applied, that is to say, in *amenorrhœa* depending upon a torpid condition of the organs of generation, and in *dysmenorrhœa* occurring under similar conditions. Its repute as a remedy for *sterility* arises from its stimulant influence upon those organs, and the same is true of its power to control passive *uterine hemorrhage* and *leucorrhœa*, especially of uterine origin. In all of these cases, its efficacy depends upon its power of stimulation. Locally, oil of savin has been applied to benumb the sensibility of exposed nerves in *dental caries*, and to promote the shrivelling of *condylomata*.

The *dose* of this oil is from two to ten drops. It may be given in emulsion, pill, or alcoholic solution.

OLEUM SASSAFRAS, *U. S.*—OIL OF SASSAFRAS.

Essence de sassafras, Fr.; *Sassafrasöl*, G.

Preparation.—Oil of sassafras is distilled in Maryland and various other parts of the United States, mostly in the neighborhood of those places where a supply of the root may be obtained without requiring much transportation. The stills used are made of copper or iron, and usually connected with a lead condenser. The roots, together with the adhering bark, are cut into chips, about ten bushels of which constitute a charge, and yield on an average about four pounds of the oil, the distillation requiring about twelve hours (Procter, 1866). If the root is dug up shortly after the tree has been cut, it appears to yield a colorless or yellow oil, but if the stumps are permitted to remain in the ground for some time they acquire a red color and yield a brown-red oil.

Properties.—As stated, oil of sassafras is either colorless or more frequently of various shades of yellow or brown-red, a difference which does not affect its quality. When carefully rectified, it may be obtained colorless, but on exposure again becomes colored. It has the odor of sassafras in a high degree, a warm aromatic taste, and a slightly dextrogyre rotary power. Its specific gravity is usually about 1.090, and increases somewhat by age. It dissolves small quantities of water, becoming lighter thereby. It is soluble in four or five parts of 80 per cent. alcohol, acquires with cold nitric acid a dark-red color, being finally converted into a red resin, and is violently acted on by bromine, but dissolves iodine quietly.

Composition.—According to Grimaux and Ruotte (1869), potassa solution extracts from oil of sassafras a body which appears to be a phenol, has the odor of eugenic acid, and assumes a bright-green color with ferric chloride. By fractional distillation, a hydrocarbon, *safrene*, $C_{10}H_{16}$, is obtained, which boils between 155° and 157° C. (311° and 314.6° F.), and is dextrogyre. The oxygenated portion, *safrol*, $C_{10}H_{10}O_2$, constitutes nine-tenths of the oil, is without action on polarized light, distils between 230° and 235° C. (446° and 455° F.), remains liquid at —20° C. (—4° F.), and yields with bromine crystals of $C_{10}H_5Br_5O_2$. On cooling the oil in a freezing mixture, Saint-Evre (1843) obtained crystallized *sassafras-camphor*, $C_{10}H_{10}O_2$, which remained solid at 5° C. (41° F.), and after being fused, congealed again at 7.5° C. (45.5° F.).

Off. Prep.—Syrup. sarsaparillæ comp., Trochisci cubebæ, *U. S.*

Medical Action and Uses.—The action and uses of this oil do not differ materially from those of numerous other essential oils. It is alleged, however, to prevent the usual effects of tobacco when mixed with it and smoked, and the narcotic action of hyoscyamus when associated with that drug. The *dose* is from two to ten drops.

OLEUM SESAMI, *U. S.*—BENNE OIL.

Huile de sésame, Fr.; *Sesamöl*, G.

Preparation.—Oil of benne is obtained by subjecting benne seeds to pressure; the yield is in the neighborhood of 50 per cent. of the weight of the seeds. About 14,000 gallons of this oil are annually imported into the United States.

Properties.—Benne oil has a yellow color, usually of a deeper hue than expressed almond oil, is nearly inodorous, has a bland and agreeable taste, and the specific gravity 0.923 at 15° C. (59° F.). Near the freezing point of water, it congeals to a yellowish-white mass, and when heated to between 150° and 200° C. (302° and 392° F.) it is decolorized. At 300° C. (572° F.) it assumes a brown color, and at 335° C. (635° F.) it commences to boil. It is a non-drying oil, and on exposure to air does not readily turn rancid. Concentrated sulphuric acid converts it into a brown-red gelatinous mass, nitric acid specific gravity 1.18 colors it gradually orange-yellow, and when of greater strength, red.

Composition.—Flückiger (Pharmacographia) found benne oil prepared by himself to contain 76 per cent. of olein; the acids of the solidifying portion appear to be stearic, palmitic, and myristic acids. A small quantity of a peculiar, probably resinous substance may be extracted from the oil by agitation with glacial acetic acid or with alcohol; the acetic solution acquires a greenish-yellow, the alcoholic solution a blue, afterwards greenish-yellow color on the addition of a cold mixture of equal weights of sulphuric and nitric acids. (See also p. 950.)

Medical Action and Uses.—In Hindostan the natives use the expressed oil for the same purposes for which olive oil is employed elsewhere; but, according to some of the native practitioners, it possesses emmenagogue virtues, and is capable, if incautiously employed, of producing abortion.

OLEUM SINAPIS, *P. G.*—OIL OF MUSTARD.

Oleum sinapis æthereum.—*Volatile oil of mustard,* E.; *Essence de moutarde,* Fr.; *Ætherisches Senföl,* G.

Preparation.—Black mustard seeds are ground, deprived of most of their fixed oil by pressure, macerated with water at the common temperature, and then distilled. A small quantity of ground white mustard seed is usually added to supply any possible deficiency of myrosin and insure the decomposition of all the myronic acid. Since oil of mustard is soluble in water, the aqueous portion of the distillate is used in macerating a fresh portion of mustard. The yield is usually about $\frac{1}{2}$ per cent., but occasionally as high as one per cent.

Properties.—The crude oil has a yellow color; after rectification it is colorless, or nearly so. It is neutral to test-paper, has the specific gravity 1.017, boils at 150° C. (302° F.), is somewhat soluble in water, freely so in alcohol and ether, and has a very pungent and acrid odor and taste. The oil dissolves completely in three times its volume and more of concentrated sulphuric acid without coloration; in the presence of other volatile oils a brown or red color is produced.

Composition.—Oil of mustard is *sulphocyanide of allyl*, $C_3H_5.CNS$. Sometimes it contains also allyl cyanide, which has a lower boiling point. It is artificially prepared by decomposing allyl bromide or iodide by means of an alcoholic solution of potassium sulphocyanide. Using an allyl iodide, obtained from glycerin and phosphorus iodide, Gerlich (1875) obtained a mustard oil which consisted of *isopropyl sulphocyanide*, $C_3H_7.CNS$, the density of which is 0.974. Mylius (1877) found in the artificial oil of commerce, besides 92.2 per cent. of allyl-mustard oil, some hydrocyanic acid, carbonsulphide, and polysulphides.

Pharmaceutical Uses.—SPIRITUS SINAPIS, *P. G.*, Spirit of mustard, *E.*, Senfspiritus, *G.*, is a solution of one part of oil of mustard in 50 parts of alcohol.

Medical Action and Uses.—Oil of mustard is a powerful and almost caustic irritant, which, for fear of accident, should never be prescribed internally. It is said that this oil may sometimes be applied as an external counter-irritant upon parts to which a blistering plaster cannot readily be adapted; but there are none upon which cantharidal collodion cannot as readily be painted as the oil. As a rubefacient it may be used dissolved in olive oil or alcohol in the proportion of about five drops to the fluidrachm.

OLEUM SUCCINI, *U. S.*—OIL OF AMBER.

Huile volatile de succin, Fr.; *Bernsteinöl*, G.

The volatile oil obtained by the destructive distillation of amber.

Origin.—Amber (*succinum*) is a fossil resin, which is principally obtained on the southern coast of the Baltic, where it is cast ashore or dug out of beds. It has also been found in the interior of Europe, and in Greenland and North America. It is hard, brittle, whitish-yellow or red-brown, semi-transparent or translucent, breaking with a conchoidal fracture, fragrant when heated, fusible at about 287.5° C. (550° F.); soluble in chloroform, but insoluble in water, alcohol, ether, and oils. Its density is 1.070. According to Goeppert, it is the exudation of *Pinitis succinifer*, an extinct coniferous tree.

Preparation.—The oil is obtained by the dry distillation of amber, succinic acid being formed at the same time (see page 77).

Properties.—Crude oil of amber is a thick, brown liquid, of a strong empyreumatic odor, and variable specific gravity approaching the density of water. Very similar products are obtained from copal, dammar, and other resins. In this state it is rarely employed in medicine, but is used in preparing

OLEUM SUCCINI RECTIFICATUM, *U. S.; Rectified oil of amber.*—This is directed to be made by mixing the crude oil with six times its volume of water, and distilling as long as oil is found in the distillate. The yield is usually stated to be from sixty to seventy per cent. of the crude oil; but Ebert (1865) prepared the crude oil, obtaining from twenty-nine troyounces of amber twenty-one fluidounces of oil, specific gravity 0.985, and on rectifying this with water, only two and a half fluidounces or nearly twelve and a half per cent. of rectified oil, specific gravity 0.903, while the density of the residue had increased to 1.019. Döpping (1847) observed that the crude oil, after having been treated with potassa solution, dilute sulphuric acid, caustic potassa, and calcium chloride in succession, distilled between 140° and 170° C. (284° and 338° F.) and left a dark-brown residue. On again treating the distillate with burned lime, and repeating the distillation, the liquid had a higher boiling point (up to 190° C., 374° F.), and was colorless.

Rectified oil of amber is colorless or yellowish, becoming darker on exposure, varying in density between 0.88 and 0.99, and in the boiling point as stated above. It has a warm acrid taste, yields, with 15 parts of alcohol, specific gravity 0.85, a turbid solution, is readily soluble in ether, fixed and volatile oils, and when heated dissolves sulphur and caoutchouc.

Composition.—In its purest state oil of amber appears to be a mixture of several oils having the composition of oil of turpentine, $C_{10}H_{16}$.

Medical Action and Uses.—Oil of amber is a powerful irritant of the skin. When taken internally it is said to be stimulant and antispasmodic. It has been given internally in *retrocedent gout* and *rheumatism*, *eruptive fevers*, *hysteria*, *whooping cough*, and *amenorrhœa*. Externally it may be employed in stimulating liniments for *rheumatism* and *paralysis*, and rubbed upon the spine in the *convulsive disorders* of children. It has been applied as a stimulant discutient to *hemorrhoidal tumors*. The *dose* is from five to ten drops, and on account of its acrid and offensive taste the oil should be inclosed in gelatin capsules.

OLEUM TABACI, *U. S.*—OIL OF TOBACCO.

Huile pyrogénée de tabac, Fr.; *Brenzliches Tabaksöl*, G.

Preparation.—Take of Tobacco in coarse powder twelve troyounces. Put it into a retort of green glass, connected with a refrigerated receiver, to which a tube is attached for the escape of the incondensable products. Then, by means of a sand-bath, heat the retort gradually to dull redness, and maintain it at that temperature until empyreumatic oil ceases to come over. Lastly separate the dark oily liquid in the receiver, from the watery portion, and keep it in a well-stopped bottle. *U. S.*

Properties and Composition.—The so-called oil of tobacco is a brown-black tarlike liquid, of a strong and very peculiar empyreumatic odor. Unverdorben (1826) recognized in it the presence of an alkaloid, which, on being boiled with diluted sulphuric acid, yields among other products *odorin* or *picolin;* it is not unlikely that others of the ternary bases, contained in animal oil (see page 961), may likewise be present in this tarry product. Zeise (1843) demonstrated the presence of butyric acid, ammonia, paraffin, empyreumatic resin, and a pale yellow oil of the formula $C_{11}H_{22}O_2$, which boils at 195° C. (383° F.). Melsens (1843) proved the presence of nicotina in the tarry matter separating in tobacco pipes, and it is most likely present in the officinal oil.

Physiological Action and Medical Uses.—In animals poisoned by this oil, the blood is uncoagulated. From two to five grains of it given to dogs two or three times a day produced gradual but complete marasmus, partial paralysis of the hind legs, loss of venereal power with softening and shrivelling of the testicles, shedding of the hair, sloughing of the eyelids, and blindness. The gums were swollen, spongy, and bleeding, and the teeth became loose. The oil of tobacco, in the form in which it accumulates in the bowls of smoking-pipes, is a virulent poison even when applied to eruptions upon the skin. The immediate effects are pallor, vertigo, faintness, nausea, vomiting, cold sweating, diarrhœa, and paralysis of the lower limbs. It is remarkable that there appears to be no fatal case of poisoning by this oil, on record, except in the case of a child in whom the oil from a tobacco pipe was applied to an ulcer on the lip. The oil of tobacco has been used to cure various chronic local *affections of the skin;* but considering its doubtful utility and the unquestionable danger of its use, it were far better that it should not be used at all.

OLEUM TEREBINTHINÆ, *U. S.*, *Br.*—OIL OF TURPENTINE.

Essence de térébenthine, Fr.; *Terpentinöl*, G.

Preparation.—Oil of turpentine is obtained by distilling the oleoresinous exudation of various species of Pinus (see Terebinthina). The crude turpentine is put into a large still, heat is applied, and water added from time to time to the contents of the still. The distillation is continued as long as oil passes over, when the resinous mass is run off through a stopcock placed at the bottom of the still, is passed through several strainers, and then constitutes *rosin* (see Resina). On condensing the distillate, the oil of turpentine separates from the water and is dipped into barrels in which it enters commerce.

Properties.—Oil of turpentine is a colorless thin volatile oil, the density of which varies between 0.86 and 0.87. When recently rectified it boils at about 150° C. (302° F.), but the temperature usually rises as the distillation progresses, and old oil does not generally commence to boil below 155° or 160° C. (311° or 320° F.). As procured from different sources, oil of turpentine shows great differences in its optical behavior, and on fractional distillation with or without water, oils are obtained differing in the degree of their influence upon polarized light. American and German oil of turpentine are dextrogyre, while the French oil has a lævogyre action. Odor and taste are peculiar, strongly terebinthinate, differing to some degree according to the source from which the oil has been obtained. When recently distilled, particularly after rectification with water, the odor is rather mild, but after exposure to air it becomes stronger, more unpleasant and pungent; the oil then contains ozone, and gradually acquires a yellowish color and thicker consistence; at the same time resin and formic and acetic acids are produced, and, in the presence of moisture, also a hydrate of the oil. Oil of turpentine dissolves in ten or twelve parts of alcohol of specific gravity 0.835, and in a much smaller quantity of stronger alcohol. Bromine and powdered iodine act violently upon oil of turpentine; nitric acid oxidizes it, the violence of the action and the final products being influenced by the strength of the acid. Gaseous hydrochloric acid unites with oil of turpentine, forming two compounds: one, having the composition $C_{10}H_{16}HCl$, is known as *artificial camphor*, is crystallizable, and has the odor and taste of ordinary camphor, but is less pungent and somewhat terebinthinate. Three compounds with water are known; one, which is called *turpentine camphor* or *terpin*, has the composition $C_{10}H_{20}O_2$, and is obtained by leaving the oil in contact with alcohol and nitric acid.

Purification.—Only rectified oil of turpentine should be used internally. The partially resinified oil is best purified by rectification with water; or it may be repeatedly agitated with small portions of alcohol, which dissolves the resin, and afterwards with water.

Composition.—When perfectly pure, oil of turpentine is free from oxygen, and has the composition $C_{10}H_{16}$. On being distilled in the presence of sulphuric acid, it is converted into several isomeric or polymeric oils, of which *tereben* has a thyme-like odor, and boils at 156° C. (312.8° F.), and *colophen* boils at 310° C. (590° F.) and shows a blue fluorescence; the latter is also obtained on the dry distillation of rosin.

Off. Prep.—Confectio terebinthinæ, Enema terebinth., *Br.;* Linim. cantharidis, *U. S.;* Linim. terebinth., Linim. terebinth. aceticum, Unguent. terebinthinæ, *Br.*

Physiological Action.—Numerous experiments upon animals prove that oil of turpentine, however applied, is rapidly absorbed, and produces, according to the quantity employed, more or less of its characteristic effects, *e. g.*, stimulation of the nervous system when relatively small doses are used, and paralyzing effects when large quantities are administered. The urine is increased and may be rendered bloody, the animals lose their muscular force and coördination, the breathing is laborious, and the action of the heart quickened. Death takes place by exhaustion and asphyxia. Its local operation is that of an irritant, causing pain, redness, and even vesication. In man the prolonged inhalation of the vapors produces vertigo, impaired vision, pain in the loins, strangury, and bloody urine, and, if very concentrated, a state of collapse. In females, menorrhagia and dysmenorrhœa are sometimes added. The internal administration of large doses of the oil has produced heat in the stomach, vertigo, confusion of mind, extreme thirst, strangury, and a frequent discharge of urine exhaling an odor of violets. The bowels are not disturbed. Sometimes it causes itching and diaphoresis. Excessive or poisonous doses occasion graver symptoms. Thus, when six ounces were taken by a woman, her body was found in a state of opisthotonos, the pupils were dilated, and the brain, lungs, stomach, and heart gorged with blood. Yet a child aged fourteen months has recovered after swallowing four ounces of the oil. It is recorded that the air of a cellar where turpentine was stored, and in which a boy was nearly asphyxiated, was found to be nearly deprived of its oxygen.

Medical Uses.—It has been used with success in almost every form of *hemorrhage*, but most successfully when the bleeding was passive. The special affections include *epistaxis*, *hæmatemesis*, *hæmaturia*, *menorrhagia*, *post-partum* hemorrhage, *purpura*, and the multiple hemorrhages occurring under the influence of the *hemorrhagic diathesis.* Even in external and traumatic hemorrhages it has proved efficient. Its efficacy justifies the opinion of John Hunter, who termed it "the best, if not the only, true styptic."

In *puerperal fever* this medicine once enjoyed a high repute, which it has in a great measure lost at the present time. For this varying estimate of its value a reason may probably be found in the indiscriminate manner of its employment. When it was prescribed in cases marked by a typhoid state in which excessive tympanites existed, there is no reasonable ground for doubting that it often successfully combated the nervous and cardiac depression of the disease, and, by lessening the distension of the abdomen, diminished the mechanical hindrances to hæmatosis. For the latter purpose it was applied as an epithem to the abdomen, as well as administered internally. This judgment appears to be justified by its recognized effects in other febrile affections of a typhoid type. In *typhus*, for example, it is of great utility both internally and externally; not only for its power of arousing the sluggish functions generally, but especially for combating the pulmonary congestion which is the gravest of the usual incidents of the disease. In *typhoid fever*, besides the general influences already mentioned, it is not only one of the most efficient remedies for intestinal tympanites, as in the cases referred to, but it also favorably controls the bronchial catarrh, and, in the advanced stages, probably exerts a local stimulant action upon the intestinal ulcers, and checks the tendency to hemorrhage from them. So, too, in *yellow fever* of a low type, it may operate not only by its general stimulation, but also by its direct action upon the stomach, tending to control the hemorrhage which is so grave a symptom in that disease. Its possible action in promoting the urinary secretion in this fever should not be overlooked. In *tympanites*, from whatever cause arising, it may become a valuable auxiliary in the treatment, whether administered by the mouth or rectum, or applied to the skin of the abdomen. When given internally for the relief of this symptom it should generally be associated with a purgative, especially with castor oil. It is most efficient in the treatment of *tænia*, and, indeed, in that of other *intestinal worms*, when a full dose of it is shortly followed by one of castor oil.

Oil of turpentine has been supposed to dissolve *biliary concretions*, and in some cases it has, when associated with sulphuric ether, appeared to favor their discharge. It seems more probable that it should tend to prevent the formation of gallstones than to dissolve them when once formed. Its diuretic virtues have caused it to be occasionally used to promote the expulsion of *urinary concretions*. Impregnating the urine, it becomes a suitable remedy for *catarrh of the urinary passages*, and in debility or *paralysis of the bladder;* and, very probably, in females this stimulation has served to cure *amenorrhœa* and to excite *uterine contractions* during labor. For these purposes, however, the oil is best administered by the rectum.

Although the *modus operandi* of this medicine in *sciatica* is totally unknown, its curative power is none the less certain. It has stood the test of a century's experience. Probably no other remedy is comparable with it in chronic examples of this painful and crippling affection. Some difference of opinion exists concerning the proper dose which should be given; some prescribing half an ounce of it at bedtime for several successive nights, and others a dose of thirty drops three times a day. The latter dose is to be preferred at first. It may be gradually increased if necessary. It has also been used in *facial neuralgia*, but apparently with inferior results. Its utility in *syphilitic iritis* is well established; it has generally been employed as a substitute for mercury in cases for which this medicine was ill adapted.

In all forms of *chronic bronchitis*, oil of turpentine has, like other terebinthinates, been largely used, formerly by internal administration, and more recently by inhalation. It is especially useful, in both ways, in cases of *fetid bronchitis* and *gangrene of the lung*, in both doubtless by stimulating the tissues to a more healthy action rather than by any disinfectant virtue. The superiority of oil of turpentine, in the latter affection, over other terebinthinates, consists in its greater stimulant virtues. The accidental discovery of the power of oil of turpentine to prevent *phosphorus poisoning* has saved many lives. The immediate administration of the antidote is, of course, desirable, not only to check the local action of the phosphorus, but also to prevent its absorption in a dangerous form. About twelve hours has been assigned as the limit within which the oil is efficacious. It is alleged that oil of turpentine which has become oxygenated by long exposure to the air is the most efficient; but results do not entirely agree upon this point. The oil must not be prescribed in any oily or albuminous vehicle, such as white of egg, milk, soup, etc., and neither mucilaginous nor alcoholic drinks should be allowed, but only water. If possible the oil should be given pure; floated on water, or in capsules. If it cannot be retained by the stomach, it may be thrown into the rectum; and its absorption by the skin from liniments and epithems, and by the lungs from an atomized preparation, or simply from the air of the chamber saturated with the fumes of the oil, may be employed as a supplementary means. The *dose* of oil of turpentine in the cases now considered is about ten drops every hour.

Oil of turpentine has long been employed *externally* as a stimulant, rubefacient, and counter-irritant in *chronic rheumatism.* It is generally mixed with olive oil, chloroform, camphor, narcotic extracts, etc. Baths of the vapor of the oil are the most efficient means of applying it; but warm water baths, in which has been dissolved a mixture of eight ounces of oil of turpentine and two pounds of washing soda, have also been used with good effect. The oil is of singular virtue in relieving *tympanites* and *colic* in various diseases, but especially when the intestinal distention is owing chiefly to atony of the bowels, as in typhoid fever. It is best applied, mixed with olive oil, to the skin, which should then be covered with flannel dipped in hot water and wrung nearly dry. In the treatment of *burns* this oil is most efficient. The affected part should first be bathed with the oil and then covered with soft lint saturated with liniment of turpentine, or ointment of turpentine, so as thoroughly to exclude the air. Traumatic *erysipelas* has been treated advantageously by the ointment just mentioned, and also by simple lotions of oil of turpentine. The same method is equally applicable in cases of *frost-bite*, and of superficial *gangrene.* An emulsion containing equal parts of oil of turpentine and tincture of camphor is said to be an efficient dressing for *carbuncles.* Indeed, there are few *ulcers* of an indolent character that are not benefited by this oil, applied either alone or in an ointment or cerate, as in the simple or compound resin cerate. Ulcers resulting from *mercurial salivation* tend to heal after being touched by the pure oil, or washed with an emulsion containing it. It has been used successfully in the treatment of *scabies.*

The *dose* of oil of turpentine as a stimulant is from five to twenty or thirty drops three times a day. Such doses are conveniently administered in gelatin capsules. As an anthelmintic from two to four fluidrachms may be given at intervals of half an hour, until three or four doses are taken. These doses are usually prescribed in an emulsion, with the addition of oil of cinnamon, cajeput, or rosemary, to diminish nausea. Besides the rubefacient preparations above mentioned, a very efficient one may be made with equal weights of oil of turpentine, acetic acid, and liniment of camphor.

OLEUM THEOBROMÆ, *U. S.*, *Br.*—OIL OF THEOBROMA.

Oleum (Butyrum) cacao, P. G.—*Butter of cacao*, E.; *Beurre de cacao*, Fr.; *Cacaobutter*, G.

Preparation.—In the manufacture of chocolate a portion of the cacao seeds are deprived of their fat by heating them gently, removing the shells, and pressing them between hot iron plates; the expressed fat is usually run into rectangular moulds, and allowed to congeal. The yield from different varieties of cacao is from 40 to 45 per cent.

Properties.—Cacao butter is a yellowish-white fat, sufficiently hard at the ordinary temperature to be broken into smaller pieces, but softens by the warmth of the hand, and melts when taken in the mouth. It has an agreeable odor, and a bland chocolate-like taste, dissolves in ether, acetic ether, and by the aid of heat in strong alcohol, separating again from the latter solution on cooling, with the exception of a small portion which remains dissolved. The specific gravity of cacao butter appears to be usually near 0.90, but is given by some authors as high as 0.961. The fusing point of cacao butter obtained from different commercial varieties of seeds has been determined by Trojanowski (1875) and Lamhofer (1877), and found to vary between 30° C. (86° F.) and 33° C. (91.4° F.). Pelouze and Boudet found it in one instance as low as 29° C. (84.2° F.).

Composition.—When saponified, cacao butter yields glycerin, oleic, stearic, and a little palmitic acid (Stenhouse, Specht, and Gössmann). It probably contains also arachic acid (Pharmacographia).

Adulterations.—When mixed with other solid fats, the fusing point and specific gravity do not afford reliable tests for determining such admixtures. Björklund (1864) proposed to dissolve 2 grams of the fat in 4 grams of ether at 17° C. (62.6° F.), and to immerse the test-tube containing the solution in water of 0° C. (32° F.); if pure, cacao butter will separate granules in not less than three minutes, but usually in five or eight minutes; if adulterated with tallow or suet, a turbidity will appear at once or within two and a half minutes, according to the quantity of the adulterant, of which 5 per cent. may thus be detected. When the congealed mixture is exposed to a temperature of about 14.5° C. (58° F.), it will gradually become clear again, if the cacao butter was pure, but not if it was adulterated.

Trojanowski and Lamhofer proved the value of this test. According to the latter, petroleum-benzin may be substituted for the ether with nearly identical results, except that the pure oil separates rather more slowly, and is always granular, while other fats render the entire liquid cloudy.

Off. Prep.—Cacao butter is an ingredient of all officinal suppositories, except three admitted by the "Additions to the British Pharmacopœia."

Medical Action and Uses.—Oil of theobroma has been used internally as a nutrient and emollient remedy in cases of chronic affections of the *lungs* and *bowels*, and externally as a dressing for excoriated surfaces, *wounds*, etc. Its mildness renders it superior to lard for the latter purposes, and it is more emollient than spermaceti. It is the most eligible material for making suppositories. Its slight tendency to become oxidized fits it to protect surgical and other steel instruments from being corroded by exposure to the air.

OLEUM THYMI, *U. S.*—OIL OF THYME.

Essence de thym, Fr.; *Thymianöl*, G.

Preparation.—The volatile oil is obtained by distilling the flowering herb of Thymus vulgaris, *Lin.*, with water. It is largely produced in France, and enters commerce either in the crude state as *huil rouge de thym*, *red oil of thyme*, or rectified as *huile blanche de thym*, *white oil of thyme*. During the year 1876–1877 the United States imported 32,707 pounds of the former, and 863 pounds of the latter kind. The red oil is frequently sold as *oil of origanum*.

Properties.—Crude oil of thyme is of a deep reddish-brown color; the rectified oil is colorless or yellowish. It has a strong aromatic odor, and a pungent, warm, and afterwards cooling taste, dissolves readily in alcohol, and varies in density between 0.886 and 0.905. It does not fulminate with iodine.

Composition.—The more volatile portion of oil of thyme consists of two hydrocarbons, *cymene*, $C_{10}H_{14}$, and *thymene*, $C_{10}H_{16}$. The former is also a constituent of oil of cumin (see p. 475). The latter boils between 160° and 165° C. (320° and 329° F.), is lævogyre, and yields with hydrochloric acid gas a liquid compound. The stearopten is *thymol*, $C_{10}H_{14}O$ (see Oleum monardæ, p. 979), and is obtained by fractional distillation of the oil, collecting only that portion which distils at about 230° C. (446° F.). By agitating the commercial oil with soda solution, Gerrard (1878) obtained only variable quantities of an oily liquid, but no solid compound, and on exposure to a low temperature, no thymol could be obtained; he concludes from this that the thymol is probably frequently extracted from the oil. He also ascertained that the strongest aqueous solution of thymol available is 1 in 1000, and that a solution of four grains of it in a fluidounce of alcohol is miscible with water without becoming turbid. Three grains of thymol are dissolved by one grain of caustic soda, and one and a quarter grain of caustic potassa. Fats and oils, when heated, are excellent solvents of thymol.

Physiological Action and Uses.—Experiment has proved that oil of thyme in the proportion of one part per thousand arrests saccharine fermentation; that it powerfully retards lactic fermentation, and checks the various processes of decomposition, even when used in relatively small quantities. It is comparatively harmless when administered internally, not disturbing digestion, but arresting gastric fermentation. It is ten times less poisonous than carbolic acid, and hence may be used even in equal quantities with a very inferior risk. Some persons find its taste and smell as repulsive as those of carbolic acid, but others claim for it an agreeable aromatic odor and taste. When taken internally by sensitive persons it causes ringing in the ears, and even deep somnolence, and collapse. It has been employed chiefly, but not exclusively, for its topical effects, to correct the *fetor* of suppurating and gangrenous *wounds* and *ulcers*, and, in atomized solution, the odor of the breath in *fetid bronchitis*. Injected into dead tissues it preserves them from decomposition; applied pure to *warts* it causes them to shrivel and disappear. In *skin diseases* it has been found useful in the same cases for which tar has so long proved to be the best topical remedy, that is to say, in *psoriasis* and chronic *eczema*, but especially in the former, and it has the advantage over tar of not staining the bed and body clothing. It is recommended to apply it in an ointment consisting of one ounce of soft paraffin, and from five to thirty grains of thymol; or in a lotion consisting of thymol, five grains; rectified spirit and glycerin, each one ounce; water, to make eight ounces.

As a substitute for the antiseptic surgical dressing prepared with carbolic acid, a solution is recommended as follows: Thymol 1 gram; alcohol 10, glycerin 20, water 1000 grams. This solution has no corrosive action on instruments immersed in it; it causes, however, a lively sensation of burning, accompanied with redness of the skin, but not with anæsthesia, and not followed by desquamation of the epidermis. Being substituted for carbolic acid in the antiseptic method of dressing wounds, the results are reported to be excellent. After forty-one out of fifty-nine operations the secretion was serous in only eight, and purulent in two; in the remainder there was absolutely no secretion. Many of these operations involved large surfaces, or were for diseased joints, etc. According to Ranke, the results obtained with thymol (antiseptically considered) are as good as those with carbolic acid; while the former presents these advantages, that the secretion of wounds treated by it is much less, and their rate of healing much quicker. Moreover, it produces no bad effects upon the system at large, and does not irritate the parts to which it is applied in solution. (*Medical Times and Gazette*, March, 1878).

OLEUM TIGLII, *U. S.*—Croton Oil.

Oleum crotonis, Br.—*Huile de croton, Huile de graines de tilly*, Fr.; *Crotonöl*, G.

The fixed oil obtained from the seeds of Croton tiglium, *Lin.*, s. Tiglium officinale, *Klotzsch.* Woodville, vol. v.; Bentley and Trimen, Med. Plants, 239.
Nat. Ord.—Euphorbiaceæ.

Origin.—This species of croton is common in the wild state as well as cultivated throughout Hindostan, and some of the East Indian and Philippine Islands, and has been introduced into Japan and other countries. It is about 15 or 20 feet high, has alternate petiolate, acutely-ovate, serrulate leaves, and terminal racemes of unisexual flowers. The fruit is a tricoccous capsule, nearly three-quarters of an inch long, each cell containing a single seed. The latter are about half an inch long, oblong, flattened upon the ventral surface, and marked longitudinally by the slightly elevated raphe. The dorsal surface is rounded. Externally the seed is of a gray-brown color, mostly more or less mottled, or of a nearly uniform blackish color, where the outer coat has been removed. The testa is brittle and incloses an oily albumen of the shape of the seed, and the foliaceous embryo. The seed is without odor, and has an oily afterwards very acrid taste.

Fig. 123.

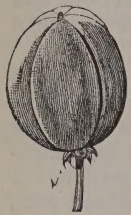


Fig. 124.

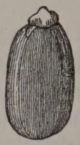

Croton tiglium, *Lin.*
Fruit. Seed.

Preparation.—The fixed oil is obtained in India and in Great Britain by subjecting the seeds to pressure. The yield is between 50 and 60 per cent. About 3700 pounds of croton oil are annually imported into the United States.

Properties.—Croton oil from India is of a pale-yellow color, that made in England is of a more or less deep reddish-brown hue, the darker color being probably due to the greater age of the seed and to the higher temperature at which the oil is expressed. It has a rather viscid consistence, is somewhat fluorescent, dissolves freely in ether, fixed and volatile oils, and varies in its behavior to alcohol, according to Warrington (1865) being more soluble in that menstruum when old and partly oxidized. At a low temperature it separates white granules of fatty acid; exposed to air it becomes more viscid, perhaps from the separation of fatty acids, and not from the presence of a drying oil, although, like the latter, it is not solidified when in contact with nitrous acid.

Composition.—The fats present in croton oil are glycerides of stearic, palmitic, myristic, and lauric acids, and of several volatile acids of the same series, like acetic, butyric, and valerianic acid; also the volatile *tiglinic acid* $C_5H_8O_2$, which was recognized by Geuther and Frölich (1870), but had previously been observed by Schlippe (1858), who considered it to be identical with angelicic acid. The chemists first named supposed tiglinic acid to be identical with methylcrotonic acid; it boils at 201.1° C. (394° F.), and in the fraction boiling above that temperature capronic, œnanthylic, or similar acids are probably present. They did not succeed in obtaining from croton oil an acid having the composition of Schlippe's *crotonic acid*, $C_4H_6O_2$. Schlippe's *crotonol*, $C_{18}H_{28}O_4$, has likewise not been obtained by other chemists; it was stated to be a yellowish viscid mass of a faint odor, and to be the rubefacient principle of croton oil. The drastic principle has not been isolated.

Tests.—The process of Schlippe for preparing crotonol has afforded us (1860) the means of detecting croton oil in other oils. The suspected oil is agitated with a solution of soda or potassa in dilute alcohol, the alcoholic liquid is separated, neutralized with hydrochloric acid, and a little of the oily layer separating is applied upon the arm, when in a few hours redness and the peculiar pustular eruption will appear. Should the quantity be small, the acidulated liquid is agitated with ether, the ether evaporated, and the residue applied.

Allied Oils.—See Curcas, page 483. The oil obtained by bisulphide of carbon from the seeds of Euphorbia lathyris, *Lin.*, has been recommended by Zander (1878) as a cheaper substitute for croton oil.

Off. Prep.—Linimentum crotonis, *Br.*

History.—Our knowledge of this medicine was derived from the Orientals through the Arabians; it having been used from time immemorial in Hindostan as a purgative and external irritant. It was introduced into Europe in 1820.

Physiological Action. *On Animals.*—The seeds, reduced to a paste and administered to dogs, produce painful purging, and after death evidences of violent inflammation of the mucous membrane of the stomach and intestine are discovered. In Java the seeds are employed for killing fish. The oil given to dogs acts rapidly as an emeto-cathartic. When injected into a vein, by one experimenter, five drops caused vomiting and purging, and death in two hours. The stomach and intestine were inflamed. The same experiment performed by others indicated an action of the oil in depressing the heart and the nervous system, but gave no evidences of irritation of the alimentary canal before or after death.

On Man.—A croton seed, when chewed, has a sweet and oily taste, followed by a bitter and acrid savor, and salivation; nausea, eructation, flatulent distension of the abdomen, colic, and diarrhœa follow. A single seed is reported, in one case, to have proved fatal. The oil, in the dose of one drop, occasions more or less of an acrid and burning sensation in the fauces and œsophagus, a sense of warmth in the stomach, nausea, and sometimes vomiting. In an hour or two some gurgling or slight colic is perceived in the bowels, followed somewhat suddenly by a watery stool with tenesmus, and heat about the anus. Within twenty-four hours, eight or ten more stools follow, and there is but little general disturbance of the economy, except considerable weakness. Sometimes, instead of producing a purgative effect, the oil causes epigastric uneasiness and oppression, palpitation of the heart, headache, feverishness, perspiration, and sleep. It would appear that the acrid principle of this oil is not the sole cause of its purgative operation, for even after being thoroughly washed with alcohol, and rendered mild to the taste as well as incapable of pustulating the skin, it is still strongly purgative. When given in enema, in the dose of three or four drops, croton oil acts purgatively.

In excessive doses this oil may act as a violent and fatal poison, producing severe pain, and general collapse, without loss of consciousness. After death no lesion of the stomach or intestines may be found. There are, on the other hand, cases in which recovery has followed excessive doses. For example, a girl six years old, having swallowed about forty-six grains of croton oil, mixed with milk and coffee, and when the stomach was empty, suffered acute gastric pain and violent and profuse vomiting. The emesis probably saved her life.

Externally, croton oil rubbed upon the skin occasionally produces purgation. Its ordinary effects are, however, local. In general, it brings out, after a few hours, an eruption of minute red pimples, which are always more numerous in proportion to the vascularity and delicacy of the skin, and are gradually converted into pustules, generally of an acuminated or rounded shape, while others are flattened and umbilicated. Many are confluent. A red areola surrounds them, and they cause severe burning and itching. They augment for three or four days and then remain stationary. Some break and others wither away. If numerous, they may form thick and extensive crusts. These are thrown off between the sixth and the twelfth day, and leave no cicatrix behind them. The endermic inoculation of the oil causes small but painful abscesses.

Uses.—In obstinate *constipation* of the bowels, and when there exists no contraindication arising from inflammation or structural alteration, croton oil is an appropriate purgative. But the observance of these conditions is very important. The oil is most appropriate when bulky doses are objectionable, and when the patient resists the administration of more usual cathartics. Of the former sort are cases of intestinal obstruction from accumulated feces, produced by simple torpor of the bowels, diseases of the nervous centres, the poison of lead, etc. Of the latter, are the frequent instances of a refusal to take medicine, among children and insane persons; but the oil should rarely be given to children. It is customary to administer it to the insane in milk or broth: a most vicious and inhuman practice, since it causes an aversion to those articles upon which the patients' lives may depend. In *lead colic* it has, to a great extent, superseded other purgatives. It should be given in the dose of one drop daily, or twice a day, and need not interfere with the simultaneous use of narcotics internally and externally. Like other active purgatives, it has been used to expel *tæniæ;* and it is even said to have produced this effect when mixed with olive oil and rubbed upon the abdomen; but many surer remedies for these parasites exist. In like manner, it has been used successfully as a drastic purgative in different forms of *dropsy;* but it is unnecessarily harsh. Its irritant substitutive action has been invoked in *dysentery;* but safer and less harsh remedies are to be preferred. In *apoplexy*, it is customary to employ it for its depletory revulsive action and for the convenience of its administration during the stupor of the attack. If the attack is one of congestive apoplexy, denoted by turgor of the face, laboring heart and pulse, etc., purgation is generally indicated; but in an opposite condition it is contraindicated.

Externally, croton oil has been used to relieve cerebral symptoms following the suppression of a cutaneous eruption and other causes; and in the various forms of *meningitis* it is the most efficient mode of counter-irritation of the scalp. It is less painful than tartar-emetic pustulation, and more permanent in its action than cantharides. It is much used as a counter-irritant in spinal *neuralgia*, but is objectionable on account of the difficulty of restricting its action to a very limited area. It has been more successful in *sciatica* than in any other form of neuralgia. For this affection it has also been recommended internally, but upon less substantial grounds. It has been applied locally in chronic articular *rheumatism*, and is undoubtedly one of the best of the topical remedies for this disease. Its moderate but steady counter-irritation renders it peculiarly valuable in cases of *chronic bronchitis* and *chronic laryngitis.*

Tinea tonsurans, or ringworm of the scalp, has been treated successfully by croton oil, which is applied pure until the characteristic eruption appears, when a poultice is used to soften and remove the crusts of the original disease, and those produced by the oil. It is recommended, when a large portion of the scalp is involved, that a small portion only should be treated at a time, on account of the irritation and fever which usually are excited.

Administration.—Croton oil may be given in emulsion, or mixed with some other oil, or in pill. Of these forms the last is to be preferred. The *dose* is from one-quarter of a drop to two drops. The following is a safe and convenient prescription: Add to two drops of croton oil enough alcohol to dissolve them, and then bread crumb in sufficient quantity. Make from four to eight pills, and direct one to be taken every hour or two. Externally, the oil may be applied by means of a feather, brush, or other convenient instrument, and friction made with a rag until the skin becomes dry. It may be used pure or mixed with castor oil, olive oil, soap liniment, alcohol, or ether; or a piece of adhesive plaster may be moistened with the oil to within a quarter of an inch of the edges, and then applied to the skin. A mixture of one part of croton oil with seven of oil of turpentine is more rapid in its action than the oil alone.

As antidotes to the *poisonous* effects of this oil, milk, olive oil, mucilage, gelatin soup, etc., may be given to envelop the acrid substance, and if it cause a tendency to collapse, opium and alcoholic liquids and warm stimulating baths should be employed.

OLEUM VALERIANÆ, *U. S.*—OIL OF VALERIAN.

Essence de valériane, Fr.; *Baldrianöl*, G.

Preparation.—The volatile oil is obtained by distilling the crushed root with water. The yield varies between ½ and 2 per cent., and is largest from valerian grown in dry localities. 5 pounds of oil of valerian were imported into the United States in 1876, and 103 pounds in 1877.

Properties.—When recently distilled from fresh root, the oil of valerian is of a greenish or yellowish color, limpid, and of a mild odor. On exposure to air, it becomes deeper yellow and brown, viscid, and acquires a strong odor. Old roots yield at once a dark and strongly odorous oil. Its taste is aromatic, somewhat camphoraceous, not burning; its density is near 0.94. It is readily soluble in alcohol, does not fulminate with iodine, and becomes purplish-black with ethereal solution of bromine, dark red with sulphuric acid, purplish-red with hydrochloric acid gas, and blue with nitric acid.

Composition.—The latest investigation is by G. Bruylant (1878), who ascertained some new facts. The hydrocarbon $C_{10}H_{16}$ was named *borneene* by Gerhardt (1841) and *valerene* by Pierlot (1859). The *valerol* of the latter differed from Gerhardt's valerol, $C_6H_{10}O$, which he believed to become oxidized in contact with air to *valerianic acid*, carbonic acid being given off at the same time. Bruylant explains the generation of valerianic acid in old oil of valerian from the decomposition of $C_{10}H_{17}C_5H_9O_2$, which is the valerianic ether of borneol. Besides this one, it contains the corresponding ethers of formic and acetic acids, the alcohol *borneol*, $C_{10}H_{18}O$, and its ether, $(C_{10}H_{17})_2O$. Gerhardt assumed the production of borneol from the hydration of borneene. (See Oleum camphoræ, page 966.)

Medical Action and Uses.—In experiments upon animals with poisonous doses of this oil, it appeared to blunt the reflex excitability after having primarily stimulated it, and to produce a similar effect when the same function was previously excited by strychnia. It has been used with advantage in *hysteria*, *chorea*, and even in *epilepsy*; but it is most efficient in the first-named disease, and in the various functional nervous derangements which, without constituting hysteria, are nevertheless hysterical. It may be prescribed in *doses* of one drop and upwards in pill, emulsion, or alcoholic solution.

OLIBANUM, *P. G.*—FRANKINCENSE.

Gummiresina olibanum, *Thus.*—*Oliban*, *Encens*, Fr.; *Weihrauch*, G.

From Boswellia Carterii, *Birdw.*, and other species of Boswellia. Trans. Linn. Soc., XXVII. t. 29, 30, 31; Bentley and Trimen, Med. Plants, 58.

Nat. Ord.—Burseraceæ.

Origin.—The genus Boswellia is confined to India, Southern Arabia, and Eastern Africa. It comprises trees with impari-pinnate leaves, serrate leaflets, small, racemose, decandrous flowers, and three-celled drupaceous capsules containing three seeds. The different species are still imperfectly known. B. Carterii may possibly be a polymorphous species, or several forms at present regarded as mere varieties may be distinct species, which grow only in two limited districts in Southeastern Arabia and in the Somali country of Eastern Africa. B. papyrifera, *Richard*, indigenous to Nubia and Abyssinia, yields a similar product, which, however, is not collected. B. thurifera, *Colebr.* (B. serrata and B. glabra, *Roxb.*), affords a soft odorous resin which is used in India as incense. The fragrant resin of B. Frereana, *Birdw.*, of the Somali country, is used in the East as a masticatory.

Collection.—The collection of olibanum in the Somali country was described by Cruttenden (1846), and in Arabia by Carter (1847), who had visited these countries three years previously. Deep incisions are made from which a milk-white exudation flows, which gradually hardens, and is then collected. Olibanum enters commerce by way of Bombay.

Description.—Olibanum consists of roundish, oblong, or irregular shaped separate tears. These vary in diameter between one-eighth and one-half inch or more, and are nearly colorless, pale yellowish, or of a reddish hue, and covered with a whitish powder, resulting from the attrition of the pieces. When broken they exhibit a flat scarcely conchoidal fracture and a waxy lustre. Olibanum has a balsamic somewhat terebinthinate odor, softens between the teeth, and has a balsamic and slightly bitter taste. Triturated with water, it yields a white emulsion; alcohol dissolves the greater part of it. When heated, it becomes soft and burns, diffusing an aromatic odor.

Olibanum of inferior quality is more deeply colored, often opaque, and more or less mixed with fragments of bark and other impurities.

Constituents.—By distilliation with water, a volatile oil is obtained, varying in quantity from 4 (Stenhouse, 1840) to 7 per cent. Kurbatow (1871) found it to consist of *olibene*, $C_{10}H_{16}$, and an oxygenated portion boiling above 175° C. (347° F.). Olibene is the chief constituent of the oil, boils at about 157° C. (314.6° F.), has a turpentine-like odor, and yields with hydrochloric acid gas a crystalline compound. The resin amounts to 56 (Braconnot, 1808) or as much as 72 per cent. (Kurbatow), and, according to Hlasiwetz (1867) has the composition $C_{40}H_{30}O_6$. The gummy matter contained in olibanum was found by Hekmeijer (1858) to agree in behavior with gum arabic.

Pharmaceutical Uses.—Olibanum is a constituent of most *fumigating powders*, for which there are a large number of formulas in existence; they contain also benzoin, storax, mastic, amber, cascarilla, orris root, sandal wood, or other odoriferous drugs, which are reduced to a coarse powder, and when used thrown upon a heated surface. *Fumigating pastilles* are made of a similar composition, and should contain about 40 per cent. of ligneous material or charcoal, and from 5 to 8 per cent. of potassium nitrate; the finely-powdered ingredients are well mixed, formed into a mass with mucilage of tragacanth, and then made in the desired shape.

Medical Action and Uses.—Although no longer officinal in either the United States or the British Pharmacopœia, olibanum is one of the most ancient, as it once was one of the most valued, of medicines. It was the frankincense of which so much is said in the Old Testament, and which was used by the Egyptians in embalming; it is spoken of in the Hippocratic writings as an expectorant in bronchial catarrh and in infantile asthma, as useful in expelling the lochia and promoting menstruation, as an ingredient of injections for leucorrhœa, and of ointments for various ulcers, including those caused by burns. Later it was applied in ointments to *chilblains*, *cutaneous eruptions*, and *inflammations of the eyes*. More recently it was an ingredient of various stimulating plasters, and its fragrant fumes were used to conceal unpleasant smells. The *dose* is stated to be from thirty to sixty grains given in emulsion.

OPIUM, *U. S.*, *Br.*—OPIUM.

Meconium, *Succus thebaicus.*—*Opium*, E., Fr., G.

The concrete juice obtained from the unripe capsules of Papaver somniferum, *Lin.*, by incision and spontaneous evaporation.

Origin and Production.—The poppy capsule, which is described elsewhere (see Papaver), contains under the epidermis a large number of laticiferous vessels which are variously branched and interlaced, and, in the unripe state of the fruit, are filled with a white milk-juice which escapes when an incision is made. For its successful cultivation the poppy requires a deep, rich, and well-manured soil, and considerable attention until the plant has sufficiently matured to permit of the collection of the milk-juice. A few days after the petals have fallen, the green capsule is scarified, with the precaution of not cutting entirely through the capsular integuments, as the juice would then flow into the capsule and be lost. In Asia Minor and Egypt one or two incisions are made transversely near the middle of the capsule, so as to run spirally around it. In India three or four vertical incisions are made from the base to the apex, and on different sides of the capsule, the instrument used for the purpose, called *nushtur*, being a three- or four-bladed knife, protected by means of twine, so as to prevent the blades from penetrating too deeply. The scarifications being made in the afternoon, the milk-juice is ready for collection the next morning, when its color will have changed from white to brown. The juice is then carefully scraped off with a knife, which is moistened from time to time with water, or, in Asia Minor, by drawing it through the mouth; in Persia oil is used to prevent the juice from adhering to the scraper.

In *Asia Minor* the juice is transferred to a poppy leaf and formed into cakes varying greatly in size—from a few ounces to two pounds or more in weight. These soft cakes are subsequently often mixed together, for the purpose of obtaining larger cakes, which are surrounded by one or two wilted poppy leaves, afterwards packed with a considerable quantity of the dry fruits of a species of Rumex, thus preventing the cakes from adhering to one another, and then transported to Smyrna or Constantinople, whence the European and American markets are chiefly supplied.

In *Egypt* opium is collected and prepared for the market in a manner similar to that just described. The production in that country at one time considerably declined, but has increased since Gastinel Bey (1865) proved that opium equal in quality to that of Asia Minor could be gathered by bestowing sufficient care upon the cultivation of the plant.

The juice gathered in *India* is usually quite soft, in consequence of dew, and after collection separates a dark-colored fluid, called *passewa*, which, together with the washings of vessels and some opium, is evaporated to a thick liquid, called *lewa*, and this is employed in agglutinating the poppy petals together, so as to form an envelope, and, after drying, a rather hard shell for the protection of the opium. The opium, which is moulded into spherical balls, requires much attention until it has been sufficiently dried for preservation. Each ball weighs a little over four pounds; forty of these are packed in separate compartments in a case, and are mostly exported to China. In the commerce of India this is known as *provision opium;* for home consumption the juice is evaporated by the heat of the sun, and formed into square or sometimes circular cakes, which are wrapped in oiled paper.

Persian opium is formed into cylindrical sticks about six inches long, each of which is wrapped in paper; or into cones or small balls about one and a half inch in diameter, the wrapper of which is sometimes marked with Chinese characters. Since 1856 Persian opium has been sent to Constantinople, and there worked over so as to resemble that of Asia Minor. At the present time it is frequently seen in European commerce, and it is imported in considerable quantity into the United States to be used in the manufacture of morphia. It often comes in cakes weighing one or one and a half pound, which are oily and always packed in *poppy trash*, *i. e.*, the dried stalks and capsules ground into coarse powder.

China produces a large quantity of opium, all of which is consumed in that country: in addition it consumes notable quantities imported from Persia as well as by far the largest portion of the opium which is exported from India. The samples which we have seen were flattish-globular in shape, and wrapped in white paper; one specimen was oily, though less so than Persian opium, and another, to judge from its black-brown color, was prepared by the aid of artificial heat, though free from empyreuma.

In *Japan*, the milk-juice is obtained by the longitudinal scarification of the poppy capsules, and the opium is formed into flat cakes which are wrapped in paper.

Numerous experiments have been made in *Europe*, and opium of excellent quality has been obtained as far north as Sweden; but European opium is not an article of commerce, and its production appears to be very limited. It is stated that Aubergier calls the opium raised by him in France *affium*, and that it is formed from the agglomeration of tears, exuded from the incisions, and entirely free from foreign admixture.

In *Algeria*, opium has been produced since 1828, in limited quantities however, and insufficient to be of any commercial importance. Rohlfs (1865) found an extensive culture of opium in the oasis of Tuat, in the northern part of the great African desert.

Opium has also been raised experimentally in Victoria, *Australia*, and was stated by Mr. Bosisto (1876) to be of good quality.

About the year 1812 opium of fair quality was produced in the *United States*, chiefly if not exclusively in New England. After the close of the war, the cultivation had to be abandoned, as it appears, mainly because the product became unsalable in consequence of extensive adulterations; more recently, however, opium culture again attracted attention, more particularly during the late civil war, when it was successfully prepared in Virginia, Tennessee, and South Carolina. Prof. Porcher (Resources of the Southern Fields and Forests, p. 26) states that in the climate of South Carolina and Georgia, the poppy should be planted in September; the plants are not killed during the winter, they thrive in the early spring, and the capsules are ready for incision in May. Several attempts made to obtain the poppy by planting in April and May failed, the seeds not coming up. A "garden square" yielded him 330 drachms of very dry opium of excellent quality.

In Asia Minor the poppy seed is sown at intervals from November to March. By following this course, failure from frosts or other causes is guarded against, and the maturing of the poppy heads is extended over a certain length of time. Since by the circular incisions made there, all or nearly all laticiferous vessels are cut, a second scarification is generally unprofitable, while an additional quantity of milky juice is usually obtained on repeating the vertical incisions after a day or two.

The *variety of poppy* cultivated in Asia Minor is the black, which has usually purple flowers and black, though occasionally white, seeds. This variety is that also which, in the experience of Aubergier in France, and of Behr and Biltz in Germany, yields opium richer in morphia than that produced from the white-flowering and white-seeded poppy. The latter is, however, by some persons considered more advantageous for collection, and appears to be the only kind cultivated in Egypt, Persia, India, China, and Japan.

The *importation* of opium by the United States has of late years been steadily increasing; it amounted to 135,305 pounds in 1867, and rose to 230,102 pounds in 1877. Of opium prepared for smoking 12,603 pounds entered the United States in 1870, and 47,428 pounds in 1877.

Description.—Opium is a more or less dark red-brown, internally sometimes yellowish-brown mass, which bears on the surface the impressions of the veins of the poppy leaf in which it has been enveloped and fragments of which are always adhering to it. When broken, some tears are usually observed in the interior, together with fragments of vegetable tissue which have been detached in scraping off the milk-juice. The interior is always moist. The cakes are either globular or more or less flattened and irregular in shape, and weigh from about 4 ounces to 2 pounds. The odor of opium is heavy and narcotic, its taste disagreeable and bitter. Examined under the microscope, some needle-shaped crystals are observed; but most of it consists of an amorphous or granular mass, aside from the vegetable tissue present. The crystals are best observed after the dry opium has been well moistened with benzol.

Smyrna, Turkey, or Constantinople opium is the only variety met with in American commerce. It has been stated above that Persian opium is often imported for the manufacture of the alkaloids. It is oily from the manner in which it has been collected. Its other distinctive characters and those of East Indian opium have already been briefly described. Both varieties contain usually a larger number of crystals than Turkey opium, and these crystals may not unfrequently be seen with the naked eye or by the aid of a lens.

Adulterations.—The principal admixtures observed by us in Turkey opium were pebbles, shot, and lead balls introduced into the interior of the cakes. When present, these admixtures generally amount to several ounces, but are only occasionally seen. Of greater importance appears to be the introduction of excessive quantities of vegetable tissue during the collection of the juice; but it is impossible to estimate its quantity or state its allowable limits. Coarse adulterations, such as the aqueous extract of the poppy plant and of the herb *Glaucium luteum*, which, according to Landerer, are sometimes made in Turkey, are rarely, if ever, seen in the imported opium, and are readily detected by the darker color and the hygroscopic nature of the product, and by the uninterrupted streak which it leaves on being drawn over paper, while good opium makes an interrupted mark. Such partly factitious opium, or fraudulent substitution of an extract having a narcotic odor, for opium said to have been of American origin, was noticed by Procter (1869) and Ebert (1873). Various kinds of resinous, saccharine, mucilaginous, and amylaceous substances, ashes, clay, gypsum, litharge, and sand have been employed for like purposes, and occasionally opium has been met with in the market which contained so little morphia and other alkaloids as to lead to the inference that these principles had been extracted. Another impurity is an excessive amount of moisture. Squibb (1860) estimated the average loss in drying to be 19.5 or 20 per cent., and in drying and powdering 20 to 21 per cent. From a record of nearly 12,000 pounds of opium, nearly the whole of which was directly obtained from importers, we find the average loss to have been 21.2 per cent.; in some exceptional cases as high as 28, or as low as 15 per cent. Bengal provision opium contains 30 per cent. of moisture.

Examination.—Hager has suggested the following course for determining the presence of adulterations: The sample is dried and powdered, and 25 grains of the powder are triturated with $\frac{1}{2}$ ounce of boiling water; the formation of a stiff paste or mucilaginous liquid would indicate the presence of starch, flour, gum, or salep. 2 ounces of water are added, and the liquid filtered; the filtrate should be of a wine-yellow color, indicating the absence of liquorice or other aqueous extracts, which would impart to the filtrate a brown color; the liquid should likewise have an acid reaction, otherwise the admixture of chalk, litharge, or ashes may be inferred. On evaporating the filtrate to one ounce, ferrocyanide of potassium or the addition of twice its bulk of alcohol should not cause any precipitate; the former test would indicate the presence of salts of heavy metals; the latter, an adulteration with gum or certain salts. The insoluble residue of opium left on the filter, after washing and drying, should weigh between 10 and 12 grains; should it weigh more, sand, clay, or other insoluble substances may be present; and, in case it weighs less, sugar, gum, or other soluble impurities are indicated. On agitating powdered opium with chloroform, the mineral impurities and starch settle to the bottom, and the latter acquires a blue color on the addition of a little iodine. Mineral impurities are likewise indicated by the amount of ash left, which for genuine powdered opium is about 6 per cent., varying, however, between 4 and 8 per cent.

Constituents.—Opium is entirely free from starch and tannin. Among the principles ordinarily found in plants, the following have been observed in opium: An odorous principle, soluble in ether, benzol, and petroleum-benzin; glucose, gum, pectin, a compound resembling caoutchouc, wax, fat, a small amount of resin, coloring matter, and that indefinite substance usually designated as extractive. The mineral constituents average 6 per cent.; and 55 or 60 per cent. of dry opium is soluble in water, but the pure milk-juice, entirely free from vegetable tissue, yields a larger percentage to water.

The most important, as well as the most interesting constituents of opium, however, are the alkaloids; in fact, the first vegetable alkaloid discovered was obtained from opium. In 1816, after a patient investigation extending over eleven years, Sertürner, apothecary at Eimbeck, in Northern Germany, announced the discovery of *morphium.* He recognized this principle as a salifiable base, in some respects related to ammonia. A crystalline powder, probably morphia, or containing it, was obtained by Ludwig as early as 1688, and was named *magisterium opii*, and in 1803 Derosne obtained this principle by precipitating the aqueous infusion of opium with ammonia, but regarded it as identical with his *salt of opium* (narcotina), which crystallized from the concentrated infusion. Seguin (1804) had likewise observed it. Since Sertürner's discovery a large number of alkaloids have been isolated from opium, which, arranged in the order in which their isolation was announced, are as follows:—

1. NARCOTINA, $C_{22}H_{23}NO_7$, discovered by Derosne (1803). This may be extracted with ether from the precipitate produced by ammonia in the aqueous infusion of opium, and from the insoluble residue of the latter by exhausting it with hot acetic acid. It crystallizes in shining prisms, yields mostly uncrystallizable salts, is a weak base, insoluble in cold dilute acetic acid, and gives a blood-red color with a mixture of sulphuric and nitric acids. When boiled for a long time with water, or heated with nitric acid, it is decomposed into *meconin*, $C_{10}H_{10}O_4$, and *cotarnia*, $C_{12}H_{13}NO_3$, which is a stronger base, soluble in ammonia, fusible in boiling water, and, on being boiled with very dilute nitric acid, is converted into *cotarnic* and *apophyllic acids*, the latter containing nitrogen. On heating narcotina with binoxide of manganese and dilute sulphuric acid, cotarnia is obtained, and in addition thereto *opianic acid*, $C_{10}H_{10}O_5$, which crystallizes in needles, and fuses at 140° C. (284° F.). When heated with hydrochloric or hydriodic acid, it parts with one, two, or three methyl groups (CH_2), and yields new bases.

2. MORPHIA, $C_{17}H_{19}NO_3$, discovered by Sertürner (1816), is described in another place (see page 913); also its derivative *apomorphia* (page 190). On heating its hydrochlorate with silver nitrate to 60° C. (140° F.), *oxymorphia*, or *pseudo-morphia*, is formed (see below).

3. CODEIA, $C_{18}H_{21}NO_3$, discovered by Robiquet, 1832. In preparing morphia by Gregory's process (see p. 914), after precipitating with calcium chloride, the chlorides of morphia and codeia crystallize together, and on redissolving them in water, and adding ammonia, morphia alone is precipitated. Codeia is easily soluble in hot water, alcohol, and ether, as well as in ammonia, but it is nearly insoluble

in potassa, and is separated by it from its salts as an oily liquid, which gradually crystallizes. It yields, with pure sulphuric acid, a colorless solution, but a blue solution in the presence of a trace of ferric salt. A similar reaction is produced with *Erdmann's reagent* (1861) (consisting of 20 grams pure sulphuric acid, and 10 drops of a mixture made with 6 drops of nitric acid, spec. grav. 1.25, and 100 grams of water). Fröhde's test liquid dissolves the alkaloid with a dingy green color, changing to bright blue, and slowly to pale yellow. Nitric acid gives a yellow solution.

4. PSEUDOMORPHIA, also called *phormia*, and oxymorphia, $C_{17}H_{19}NO_4$. This was discovered in opium by Pelletier and Thiboumery (1835), and may be obtained from morphia (see above). It is a fine crystalline powder, is insoluble in water, alcohol, ether, and chloroform; does not unite with acetic acid; yields, with hydrochloric acid, a salt sparingly soluble in cold water, and is colored red by nitric acid, and blue by ferric chloride, in which behavior it resembles morphia.

5. THEBAINA or *paramorphia*, $C_{19}H_{21}NO_3$, was discovered by Thiboumery (1835). It forms silvery scales; is soluble in ether, but insoluble in water and alkalies; and is colored red, afterwards yellow, by sulphuric acid; yellow by nitric acid; orange-red by Erdmann's test; and is rendered orange-yellow, and finally colorless by Fröhde's reagent.

6. NARCEIA or *narceina*, $C_{23}H_{29}NO_9$, discovered by Pelletier (1835), is in white silky needles, which are insoluble in ether and sparingly soluble in cold alcohol and water. Fröhde's reagent renders it brown-yellow, yellowish, and finally colorless. Erdmann's test produces a deep yellow, brown-yellow, and finally a deep orange color. Iodine not used in excess produces a blue color, nitric acid a rapidly fading yellow color. The blue color obtained by Pelletier, on the addition to narceia of strong hydrochloric acid and a small portion of water, is not observed with the pure alkaloid, according to Winckler, Anderson, and others.

7. PAPAVERINA, $C_{21}H_{21}NO_4$, discovered by Merck (1848), forms colorless needles or prisms, which are slightly soluble in cold ether and alcohol. Nearly all its salts are sparingly soluble in cold water and dilute acids. Sulphuric acid colors it deep purple or violet blue, which changes to green on the addition of potassium nitrate. Fröhde's reagent renders it bright violet, blue, then yellowish, and finally colorless. According to Hesse (1871), pure papaverina yields with warm sulphuric acid a faintly blue solution.

8. RHŒADINA, $C_{21}H_{21}NO_6$, discovered by O. Hesse (1865), is in white tasteless prisms, which are nearly insoluble in ether, alcohol, benzol, chloroform, water, and ammonia, and which yield with dilute acids tasteless and colorless solutions, acquiring an intense purple color on the addition of strong hydrochloric or sulphuric acid. Besides the coloring matter, an isomeric bitter base, *rhœagenina*, is formed in this reaction. The color produced by acids with Merck's *porphyroxin* (1837) depends on the presence of some rhœadina.

9. CRYPTOPIA, $C_{21}H_{23}NO_5$, was discovered by T. and H. Smith (1867). It crystallizes in minute prisms, is sparingly soluble in water, ether, benzol, and cold alcohol, dissolves in potassa and chloroform, and forms bitter salts, which have a pungently cooling taste, and usually produce a jelly-like mass when dissolved in hot water. Sulphuric acid colors it blue, the color changing to orange-yellow on the addition of potassium nitrate.

The following alkaloids were discovered by O. Hesse (1870 and 1871), and may be prepared from the mother liquors left in the preparation of morphia by Gregory's method :—

10. LANTHOPIA, $C_{23}H_{25}NO_4$, is crystalline, tasteless, sparingly soluble in acetic acid, alcohol, ether, and benzol; is readily soluble in chloroform; is colored orange-red by nitric and pale violet by sulphuric acid, the latter color changing to dark brown on heating.

11. MECONIDIA, $C_{21}H_{23}NO_4$, is amorphous, easily soluble in alcohol, ether, benzol, chloroform, and aceton. It yields very bitter unstable salts, and is

dissolved by sulphuric acid with an olive-green, and by nitric acid with an orange-red color.

12. Laudania, $C_{20}H_{25}NO_4$, is crystalline, sparingly soluble in ether and cold alcohol, soluble in benzol, chloroform, and alkalies; in ferric chloride with an emerald-green, in nitric acid with an orange-red, and in sulphuric acid with a rose-red color, the latter changing to violet on heating. The hydriodate is sparingly soluble.

13. Codamia, $C_{19}H_{23}NO_3$, crystallizes from ether in large six-sided prisms, is easily soluble in chloroform, benzol, ether, alcohol, and boiling water; forms amorphous bitter salts, and dissolves in nitric acid with a dark green, and in sulphuric acid with a blue color, changing to green and dark violet on warming.

14. Deuteropia, $C_{20}H_{21}NO_5$, homologous with cryptopia, requires further investigation.

15. Laudanosia, $C_{21}H_{27}NO_4$, is soluble in alcohol, ether, and warm benzol; the crystals fuse at 89° C. (192.2° F.). It neutralizes acids, and yields with hydriodic acid a sparingly soluble salt.

16. Protopia, $C_{20}H_{19}NO_5$, resembles cryptopia, and is with difficulty soluble in ether and alcohol. The solutions of its salts do not gelatinize.

17. Hydrocotarnia, $C_{12}H_{15}NO_3$, crystallizes in large colorless prisms, fuses at 50° C. (122° F.); volatilizes, partly unchanged, at 100° C. (212° F.); is easily soluble in ether and alcohol, and forms readily soluble salts.

From many of the above alkaloids derivatives have been obtained, which are highly interesting in a scientific point of view, and which prove that at least between some of them there exists evidently a close relation. It is not unlikely that some of those enumerated above are the decomposition products of others. This may most likely be affirmed to be true of Wittstein's *metamorphia* (1860), which was obtained in preparing morphia by Mohr's process (page 915), but has not been observed since. It liberated iodine from iodic acid, was colored red by nitric acid, but was not affected by ferric chloride. Hinterberger's *opiania* was proved by Hesse to be impure narcotina.

The *proportion* in which the alkaloidal constituents of opium are present in the drug is, without doubt, largely influenced by the climate, the nature of the soil, and the treatment to which the milk-juice is exposed in obtaining the opium. Most of the Pharmacopœias require dried opium to contain not less than 10 per cent. of morphia; good Smyrna opium frequently contains between 12 and 15 per cent. of it; but cakes taken from the same case are apt to vary considerably. Egyptian opium usually contains a smaller amount of morphia, varying from 6 to 12 per cent. Persian opium varies to a still greater extent, but much of that found in commerce is equal to the ordinary qualities of Turkey opium. East Indian opium, as a rule, is weak in morphia. It is sometimes as low as 2.5 per cent., more frequently perhaps between 3.5 and 5 per cent., but occasionally as high as 8 or 9 per cent. Most of the opium made in Europe has been of good and even of excellent quality. French opium yielded 14.4 to 22.8 (Guibourt), German opium 16.5 to 20, and from white poppy 6.8 per cent. (Biltz) of morphia. Opium made in Algiers from red poppy yielded 10.4 to 17.8 per cent., and from white poppy 1.5 to 8.5 per cent. of morphia. Several morphiometric assays of opium grown in the United States have been recorded; the lowest percentage of morphia, 4, was observed by Grahame; Procter obtained from other samples, 7.4 and 9.15, Flint 9.34, and Wayne 10.2 per cent.

The other alkaloids have been observed in the following proportions:—

Narcotina 1.3 to 10.9 per cent.
Pseudomorphia 0.02 per cent.
Narceia 0.02 to 0.1 (0.7) per cent.
Rhœadina minute.
Lanthopia 0.005 per cent.
Codamia 0.003 per cent.

Codeia 0.2 to 0.4 per cent.
Thebaina 0.15 (to 1.0) per cent.
Papaverina 1.0 per cent.
Cryptopia minute.
Laudania 0.005 per cent.

Meconic acid, $C_7H_4O_7$, was discovered by Sertürner, and is obtained by precipitating the concentrated infusion of opium with calcium chloride, and decomposing the calcium meconate by treating it repeatedly with warm diluted hydrochloric acid. It crystallizes in micaceous scales or rhombic prisms containing $3H_2O$, dissolves in four parts of boiling water, and is also soluble in alcohol. Opium yields 3 to 4 per cent. of it. It is a tribasic acid and imparts to ferric salts a deep-red color, which does not disappear on the addition of dilute hydrochloric acid (difference from formic and acetic acids) or by the chlorides of gold or of mercury (difference from sulphocyanides). When boiled with water, or more rapidly when boiled with dilute hydrochloric acid, meconic acid is decomposed into carbonic acid gas and crystallizable *comenic acid*, $C_6H_4O_5$, which on being heated yields a sublimate of *pyrocomenic acid*, $C_5H_4O_3$. The two new acids likewise redden ferric salts, the last one less deeply than the former.

T. and H. Smith (1862) exhibited *thebolactic acid* as one of the constituents of opium. This acid has the composition and physical properties of lactic acid, and, according to Buchanan (1870), is identical with the latter. It is present to the extent of about 1¼ per cent., and is probably the decomposition product of another constituent of poppy-juice.

Meconin is obtained from narcotina (see page 1012), exists also in opium, and forms colorless shining prisms, which are inodorous, bitter, soluble in alcohol, ether, and slightly soluble in water. It was discovered by Dublanc (1832), and is also known as *opianyl*. It melts in water at 77° C., and in the air at 110° C. (230° F.), and, when evaporated with slightly diluted sulphuric acid, gives a green color.

Meconoiosin, $C_8H_{10}O_2$, was obtained by T. and H. Smith (1878) from the mother liquors left in the isolation of meconin, from which it separates in an impure state as brown leaf-like crystalline masses. When pure it is colorless, is freely soluble in alcohol, ether, and hot water; fuses at 88° C. (190.4° F.), and on evaporation with dilute sulphuric acid yields a red color, changing to purple.

Morphiometry.—In view of the variable quality of opium, and of its liability to adulteration, the determination of the amount of morphia in it is frequently necessary, and must not be neglected if uniformity of strength of the pharmaceutical opium preparations is desired. The U. S. Pharmacopœia requires dried opium to yield not less than 10 per cent. of morphia by the officinal process; 100 or 150 grains (10 grams) of opium should be used for the purpose. The British Pharmacopœia has adopted the method of Thiboumery and Mohr, and accordingly gives the following directions:—

"Take of Opium one hundred grains; Slaked Lime one hundred grains; Distilled Water four ounces. Break down the opium, and steep it in an ounce of the water for twenty-four hours, stirring the mixture frequently. Transfer it to a displacement apparatus, and pour on the remainder of the water in successive portions, so as to exhaust the opium by percolation. To the infusion thus obtained, placed in a flask, add the lime, boil for ten minutes, place the undissolved matter on a filter, and wash it with an ounce of boiling water. Acidulate the filtered fluid slightly with diluted hydrochloric acid, evaporate it to the bulk of half an ounce, and let it cool. Neutralize cautiously with solution of ammonia, carefully avoiding an excess; remove by filtration the brown matter which separates, wash it with an ounce of hot water, mix the washings with the filtrate, concentrate the whole to the bulk of half an ounce, and add now solution of ammonia in slight excess. After twenty-four hours collect the precipitated morphia on a weighed filter, wash it with cold water, and dry it at 212° F. It ought to weigh at least from six to eight grains."

Mayer (1863) recommended a similar method, but substituted baryta for lime, and, instead of weighing the morphia, estimated it by his test solution.

The following method is recommended by Flückiger and Hanbury (Pharmacographia, p. 59). Mix seven to ten grains of well-dried powdered opium with thrice its weight of coarsely powdered pumice stone, pack the mixture in a percolation tube, and extract the narcotina, wax, and coloring matter by boiling ether. Moisten the residue in the tube with a very little spirit, and exhaust with water, if necessary very slightly acidulated with acetic acid. The percolate should be equal to about twenty times the weight of the opium, and is mixed with a very slight excess of ammonia. After the repose of a day or two, the morphia will be found in crystals attached to the sides and bottom of the glass. It may be dried and weighed as *crude morphia*, yet it should be recrystallized from boiling spirit of wine (0.822), at least once.

Numerous other processes and modifications have been recommended. The principal difficulties encountered in most of them are (1) the large quantity of water required for extracting the morphia, frequently rendering the concentration of the solution necessary, which should always be accomplished at a moderate heat; and (2) the impurities which are always precipitated with the morphia, and which consist of coloring matter with or without narcotina; the latter may be removed by ether, but, in decolorizing the precipitate either by alcohol or with the aid of animal charcoal, there ensues inevitable loss.

History.—Although opium was known to the Greeks, they appear to have been but slightly acquainted with the virtues which in later times secured its pre-eminence as a medicine; and although its uses were subsequently multiplied, they were not generally recognized until the Arabian school became supreme in the middle ages, nor was opium commonly employed until the seventeenth century. So many ages were required to establish the use of a medicine of which it has been said that "a physician without opium is a soldier without weapons"!

Physiological Action. *On Animals.*—In the lower animals opium affects the spinal marrow more than the brain, and the latter organ in proportion to the rank of the animal among organized beings. Experiments upon frogs prove that opium throws these animals into tetanic spasms, however it may be introduced, and whether the brain is detached or not. The same effects are produced in lizards. Birds will bear enormous doses of opium in comparison with those which may be given to man; but its effects are by no means uniform, for in individual cases the narcotic exceeds the tetanizing or paralyzing influence of the drug. Not infrequently a pigeon, for example, will survive the ingestion of twenty grains of opium, a dose far exceeding that which would be fatal to the strongest man; yet the same bird will, under the influence of the hypodermic injection of a relatively small dose of morphia, succumb, and usually with a predominance of spinal phenomena. A similar illustration is presented by herbivorous quadrupeds; for while even thirty grains of opium produce no effect when introduced into a rabbit's stomach, sleep and contracted pupils are produced by throwing laudanum into the pleural cavity, or a solution of morphia into the connective tissue. Unless we suppose that the active constituents of opium are decomposed in the stomach of these animals, such opposite results appear to be quite inexplicable.

On Man.—In doses varying from a quarter of a grain to one grain, opium produces usually a soothing and luxurious calm of mind and body, followed, in the course of forty or fifty minutes, by a disposition to sleep; or, if sleep does not take place, the body and mind enjoy a sense of repose from external impressions, while the mind is filled with dreamy and generally pleasant ideas. The pulse at first is quickened, but gradually becomes slower, the mouth grows dry, and the skin moist. Excited consciousness is followed by sleep, which is natural in its phenomena, and from which one awakes refreshed. Larger doses, as from one to three grains, occasion turgor and redness of the face, heat and fulness of the head, flashes of light before the eyes, and contraction of the pupils. The mind is excited, even to delirium; the pulse full, tense, and frequent; the skin is hot and dry, and often there is vomiting. Depression follows, with a slow and sometimes irregular pulse; dulness oppresses all the functions of relation, and the mind is torpid; the muscles lose their co-ordinating action, and the gait is sluggish and staggering. Deep sleep, or rather coma, succeeds; the breathing is stertorous, the skin pale and damp, and the hands and feet cold. The return to consciousness is attended with depression of mind and body, headache, thirst, nausea, and constipation. In narcotism by opium, when an excessive dose has been taken, no stage of excitement occurs; giddiness is speedily followed by insensibility and immobility, the respiration is slow and stertorous, and then scarcely perceptible; deglutition is suspended; the pupils are extremely contracted; the face is pale and cadaverous; the muscles of the limbs are relaxed. Vomiting sometimes occurs, but more usually in fatal cases coma continues until death, which is sometimes preceded by convulsions. After death from opium poisoning the convolutions of the brain are flattened; the vessels of the cerebro-spinal axis gorged with black blood, and the capillaries of the brain on section give out minute drops of the same fluid. A serous liquid is usually found in the ventricles of the brain and beneath the cerebral surface of the arachnoid. The lungs, heart, liver, and spleen are in most cases distended with dark and fluid blood.

To render more intelligible the operation of opium, it is necessary to point out the details of its action upon several of the organs. Contraction of the pupil is attributed, on the one hand, to its sedative action upon the sympathetic nervous system, in consequence of which the capillary bloodvessels of the iris become dilated and distended, and the pupil consequently contracted; on the other hand, it is ascribed to a stimulation of the oculo-motor centres. The former opinion seems the more probable of the two. Opium affects the digestive function by blunting the gastric sensation to which we give the name of hunger, and diminishing the demand for food by checking all the tissue changes which create that demand. At the same time it increases thirst, probably by rendering the gastric mucous membrane dry, as well as by accumulating solid effete matters in the blood. In the same manner it impedes digestion and retards absorption. The vomiting which it sometimes occasions, even when administered by the rectum or when morphia is given hypodermically, appears to be of cerebral origin. Opium tends to constipate the bowels by benumbing their muscles, as well as by diminishing their proper secretions, and those of the liver and pancreas. When habitually used these effects of the drug become less marked. As already mentioned, the primary effect of a medicinal dose of opium is to render the pulse fuller and more frequent; but, as the soporific operation is developed, the pulse becomes slower without losing its fulness. The ultimate narcotic effects upon the pulse are to render it small, weak, and irregular. That these phenomena arise through the action of opium upon that portion of the nervous system which regulates the movements of the heart and arteries must be taken for granted; but the attempts made to explain it by defining the special nervous centres upon which it depends, and their mode of action, are more ingenious than satisfactory. The same remark is measurably applicable to the action of opium upon the respiration. That action is rendered progressively slower, until in complete narcotism it is scarcely perceptible. Hence the blood is but partially oxygenated, and, being unfit for a return to the heart, it stagnates in the lungs. Hence, too, the blood of those who perish in opium narcosis is intensely black, and death occurs by gradual asphyxia. Hence, moreover, the most direct remedy for this condition is the introduction of oxygen into the lungs. Upon the kidneys, as upon all other glands, the action of opium is to check secretion, and at the same time to prevent the discharge of what is secreted by paralyzing the bladder. Its power of diminishing renal secretion is strikingly exhibited in diabetes and hydruria. While diminishing glandular and mucous secretions, opium greatly augments the perspiration, so that a conspicuous symptom among its toxical effects is profuse sweating, and it may be used as one of the surest and most perfect of all diaphoretic medicines. It is very apt to excite itching of the skin, and often produces an erythematous eruption.

The attempts to explain the operation of opium have not been much more satisfactory than in the case of other really efficient medicines. Its local anæsthetic action, and that which its internal use manifests when less than soporific doses are administered, are absolutely unintelligible. Its soporific action, it can scarcely be doubted, depends in part upon this same anæsthetic virtue exercised upon the brain tissue. In part, also, it seems to be explicable by the power, several times above referred to, which opium exerts in contracting the capillary bloodvessels, and thereby diminishing the supply of the natural stimulant of the organ, the blood. This view is rendered more probable by the consideration that belladonna, which prevents sleep, dilates the capillary bloodvessels as much as opium contracts them. It is further supported by the fact that poisonous doses of opium, producing not sleep but narcotism, dilate the capillaries by paralyzing them. Yet, after all, nothing known of the action of opium can dispense with that innate quality of the drug, our ignorance of whose nature used to be concealed under the delusive phrase "vis dormitiva."

It must be constantly borne in mind that the action of opium, like that of all agents which especially influence the nervous system, is greatly modified by numerous causes besides its mere dose. Thus it acts with extreme energy in the very young, because their nervous systems are highly susceptible; and ordinary doses are unsafe in the old, because, their eliminating functions being feeble. the medicine remains in their blood. For the former reason, probably, females are, as a rule, more readily affected than males by opium. All nervous, susceptible persons feel its influence speedily, and often in an abnormal manner, being unduly excited by ordinary doses. On the other hand, as in the case of alcohol, there are persons who can take with impunity doses of opium which to others would be distressing or even fatal. There are those, also, in whom the habit of using opiates has created a relative insensibility to the action of medicinal doses. In other cases extreme pain, like that of tetanus, or biliary and nephritic colic, may neutralize the narcotic operation of the largest medicinal doses.

The several constituents of opium which have been isolated by chemical analysis manifest various modes of action, which differ more or less widely from that of opium itself. While morphia, as we have shown elsewhere, very nearly represents the crude drug, and codeia, meconina, papaverina, cryptopia, and narceia share with it a certain soporific virtue, the remaining elements, narcotina, papaverina, thebaina, etc., are almost, if not entirely, destitute of this quality. The following statements represent the ambiguous condition of existing knowledge on these subjects:—

Narcotina was first introduced as an antiperiodic, and, although freely given, was not suspected of possessing narcotic properties. Experiments upon animals prove it to be eminently a tetanizing agent, and productive at the same time of great depression; yet some observers report its possession of a slight narcotic power. According to others, this power is distinctly manifested in man by doses of from ten to twenty or thirty grains; yet it is certain that it has been administered as a tonic and antiperiodic in thirty grain doses, without producing any narcotic effects. The conclusion almost necessarily is, that the alkaloid was not pure in the former case, but contaminated with morphia. *Papaverina* is, on the one hand, alleged to be hypnotic, even the "prime hypnotic element of opium," an arterial and nervous sedative; and, on the other, it is by turns pronounced inert, tetanizing, relaxing, and a heightener of reflex action. Physiological experimenters have demonstrated that *thebaina* is eminently a convulsifying agent, "the most potent of all the poisonous constituents of opium." In man it is anodyne and soporific in the hypodermic dose of a grain and a half, which is nearly equivalent to a quarter of a grain of a salt of morphia, and it does not occasion headache and nausea. *Cryptopia* appears to be closely analogous in its action to thebaina, tetanizing some of the lower animals, convulsing others. In man it acts like morphia, but without the unpleasant consequences due to the latter alkaloid. It is stated to be about one-fourth as strong as morphia. *Meconin*, when administered even in large doses, hypodermically to large animals, and by the mouth to man, appears to be quite inert; but hypodermically, in doses of from half a grain to a grain and a half, it produces in man a moderately hypnotic effect. The action of *codeia* upon animals seems to differ with the dose and mode of administration; one grain injected hypodermically into a rabbit producing rapidly fatal tetanus, while ten grains introduced into the stomach of a similar animal occasioned only a peaceful and prolonged sleep, from which, however, it was easily aroused. By the former method it is much more speedily fatal to these animals than an equal dose of morphia. On awaking spontaneously from the sleep produced by codeia, animals are neither paralyzed nor dull, as they are after morphia sleep. Given to man in the dose of a grain and a half, it has produced marked gastric disturbance, congestion of the head, dulness of the mind, and tremor; but in the dose of one-third of a grain it causes calm and refreshing sleep, does not produce perspiration, cutaneous eruptions, nausea, vomiting, or constipation.

Finally, *narceia* was once proclaimed as possessing all of the virtues, without any of the defects, of morphia, and as being operative in an equal dose. The usual contradictions of physiological experiment and therapeutical observation have only left the fact to survive, that, being a feeble though pure hypnotic in the dose of five grains and upwards, and being, at the same time, rare and costly, it is practically useless as a medicine.

Medical Uses.—The different modes of action of opium, according to its dose, upon the two great vivifying elements of the animal economy, its stimulant and sedative operations upon the nervous and circulatory systems, and its directly anæsthetic influence in all doses, render it the most useful of all medicines, as well as the most multifarious in its applications. It relieves pain, allays agitation, delirium, and spasm, restrains tissue change, secretion, and hemorrhage, and both directly and indirectly supports the powers of the system. By the possession of these manifold virtues, it becomes the most fitting associate of numerous other medicines, the operation of which it moderates, exalts, or directs.

Fevers.—It is an old precept, which all judicious experience has confirmed, that opium ought not to be prescribed at the onset nor at the climax of a continued fever, but during the augment to appease its violence, and during the decline to support the strength and calm the nervous symptoms which denote exhaustion. In *typhus*, its greatest usefulness is not when the strongest tendency to stupor exists, but when muttering delirium, jactitation, tremor, and spasm denote exhausted nervous power; but even then it must be used in such doses only as revive, and not in such as tend to oppress, the brain. In the rarer cases of this disease presenting violent delirium, a furious aspect, suffusion of the eyes, constant raving and muttering, and perfect sleeplessness, moderate doses of a liquid preparation of opium, associated with tartar emetic, according to a former practice, or with veratrum viride or digitalis, as more recently employed, will often render the patient tranquil and induce refreshing sleep. These remarks are equally applicable to all forms of disease when the *typhoid state*, characterized by the above phenomena, is present, and especially to *typhoid fever*, and to *smallpox*, as it occurs in adults. But opiates in the diseases of children, and especially in their eruptive fevers, are seldom useful, and often involve serious risk. Another object of employing opium in the exanthematous fevers is to hasten the development of the eruption when it is tardy and imperfect. Under such circumstances, the medicine should be given in small and repeated doses, and associated with external heat and rubefacients, and internal diffusible stimulants. Before the introduction of cinchona, opium was generally used to prevent the paroxysms of *periodical fevers*, which it did by creating a vascular excitement opposed to the formation of the chill, and inducing artificially a diaphoresis which also prevented that stage of the attack. In the same manner, it is often now associated with quinia, whose specific operation it favors. Another mode of using opium in intermittent fever is to administer it in so large a dose as to hold the nervous system in a state of immobility, and so prevent the formation of the paroxysm.

Inflammation is less directly under the control of opium than idiopathic fever, yet its judicious employment, by lessening pain, tends to prevent an aggravation of the disorder, and to allow the natural recuperative powers their full operation. In chronic inflammations, also, attended with constitutional irritation and hectic fever, opium exerts a salutary restraining influence. After severe operations, it tends to prevent the irritative fever which the shock of pain and loss of blood, and the consequent reaction, tend to excite. As a rule, the dose required is large and sedative. In *hemorrhage*, even of the active sort, opium is sometimes of service by diminishing the agitation upon which its continuance depends, and especially by allaying the excitability of the nervous system of the heart; but its greater utility is in cases of passive hemorrhage accompanied by a similar excitability. Possibly, also, it may directly contract the capillaries. In senile *gangrene* it is generally employed, probably on account of its analgesic and stimulant operation.

Pain.—All forms of pain are palliated by opiates, but the more independent pain is of material lesions, as in pure *neuralgia*, the more efficient are these remedies, unless, perhaps, when the narcotic operation suspends the action of the physical cause of pain. All forms of *spasmodic pain*, of the bowels, bladder, uterus, gall and urinary ducts, etc., are lessened by suspending the spasm in which the pain arises. Pain due to movements of the affected part is directly palliated by opium, and indirectly by promoting rest. In nearly all painful disorders, the dose of opium must be proportioned to the degree of pain. The tolerance of large doses of the drug during severe pain, and also in prolonged spasmodic attacks like tetanus, is a remarkable fact. Opium is seldom appropriate for pain within the head; it may dangerously mask this symptom in other cases where pain is the chief indication of the disease. Of the latter strangulated *hernia* is an example.

Sleeplessness is relieved by the direct action of opium, and also indirectly, in so far as opium removes the cause that prevents sleep, whether it be pain, mental excitement, or exhaustion, etc., but very often it fails of its effect, although given in large doses, in such excessive excitement as occurs in *mania a potu*, acute *insanity*, *meningeal inflammation* in some of its forms, etc. Moreover, if long continued, its utility as a hypnotic is more than counterbalanced by the derangement of digestion, secretion, etc., which it induces, particularly as its original effects can only be maintained by largely increased doses of the drug. In *puerperal insanity*, it is more beneficial than in other forms of mental disorder, particularly when morphia is used hypodermically. The treatment of *delirium tremens* by large doses of opium, which at one time prevailed, was most unfavorable in its results; and if the drug is used at all in this disorder, its doses should be small and repeated, so as to produce a primary stimulant and not a narcotic operation. In *epidemic cerebro-spinal meningitis*, opium is probably the most efficient of all the remedies that have been employed. But its utility is most conspicuous in those cases of the disease in which spasm (*i. e.*, spinal irritation) predominates over septic phenomena, and when it is administered steadily from the commencement of the attack. *Sunstroke*, marked by nervous symptoms, such as convulsions, twitchings, delirium, and general excitement, is greatly benefited by the hypodermic injection of morphia. This medicine may be used as a palliative in *epilepsy*, *hysteria*, *eclampsia*, and *spasm of the glottis;* and although it is contraindicated in obstruction of the kidneys, as in Bright's disease, it is nevertheless of great value in *uræmic convulsions*, especially when used in the form of hypodermic injections of morphia.

In obstinate cases of *chorea* the sustained use of opium has sometimes been followed by a great reduction of the spasmodic movements, and even by cure. Hardly any remedy has effected as much good in *traumatic tetanus* as opium, even when given by the mouth, although a large portion of the drug is wasted by this mode of administration. The liquid preparations are preferable, and superior to these again is the hypodermic injection of morphia. Neither method should exclude the due employment at the same time of other remedies, and especially of counter-irritation of the spine, and the use of alcohol. In this disease larger doses of opiates are required than in any other. In the somewhat analogous affection produced by *strychnia poisoning*, subcutaneous injections of morphia have proved curative. The use of opiates in *neuralgia* is most efficient when the salts of morphia are injected hypodermically, as is elsewhere at greater length described. (See Morphia.) This statement applies to internal as well as external neuralgia.

In diseases of the respiratory organs *pain* and *cough* are the symptoms which especially call for the use of opiate preparations, which relieve the former directly as well as by diminishing the violent movements accompanying the latter symptom. So far as the pain caused by coughing depends upon pleural inflammation or upon the action of muscles affected with rhumatism, opium affords certain relief, while it palliates also the painful sensations accompanying acute bronchitis. But as coughing is largely a conservative act, tending to prevent the accumulation of secretions in the bronchia, opium must not be employed in such doses as tend to prevent this salutary operation; hence it must be cautiously used, if at all, when the bronchia are filled with their secretions. In the forming stage of *pulmonary catarrh*, or *bronchitis*, when the air tubes are dry and irritable, and coughing painful, opium, especially with ipecacuanha, as in Dover's powder, will sometimes mitigate or even terminate the attack by promoting the pulmonary and cutaneous secretions. Opium has been used in the form of morphia, hypodermically, with reported advantage in arresting the development of *autumnal catarrh*. In *pneumonia* and *pleurisy* its use should be restricted to moderating cough and pain; and the same may be said of chronic *phthisis*. In the latter, if habitually used, it is very apt to impair digestion, and hasten the patient's decline, but is nevertheless almost indispensable when the cough is harassing. It may sometimes be given in an atomized solution more efficiently than when otherwise administered. In *asthma* hypodermic injections of morphia are efficient palliatives. In the various affections of the heart, of which *angina pectoris* is a more or less frequent symptom, opium, but still more morphia, is an invaluable palliative, and that without too closely regarding the special lesion upon which the pain and the disordered action of the heart depend. Of heart lesions which accompany such attacks those of the mitral valve are the most frequent.

Among diseases of the digestive organs the symptoms most appropriately treated by opium are *vomiting*, *pain*, and *diarrhœa*. All forms of vomiting are more or less under its control, as that of *sea-sickness*, of *pregnancy*, of *reflex irritation* generally, and of diseases affecting the stomach itself. In the last opium is often given in the form of an old or hard pill; but the hypodermic injection of morphia is usually more efficient. *Simple ulcer* of the stomach as a cause of vomiting is sometimes treated with opium and its preparations; but they are unnecessary when a proper regulation of the diet, with bismuth or lime-water, is employed. In pure *gastralgia* these medicines are often extremely valuable as palliatives, but other means are required to cure the disease through the removal of its cause. When used, they should be administered ten or fifteen minutes before meals, as well as when a paroxysm is imminent. Of the use of opiates in *diarrhœa*, it may be remarked that the less this symptom depends upon material lesions or upon irritating crude ingesta, the more efficient are they as remedies. Indeed they only hasten somewhat the natural cure by moderating the peristaltic action, and diminishing the secretions of the intestine. Otherwise they act only as aids to absorbents and astringents, as chalk, tannin, etc. In *dysentery* opium is of less value for its curative properties than as a palliative of the tormina and tenesmus, which belong to the active forms of this disease; but even these symptoms are more successfully relieved by the evacuant method, either alone or in alternation with the administration of opium by the mouth, and by the rectum in enemata or suppositories. When once the violence of the disease is subdued, moderate doses of opium greatly hasten its termination. In the chronic form of dysentery the main reliance must be upon diet, especially upon a milk diet, but opium with astringents is the best medicinal remedy. In *lientery* opium, with or without astringents, is almost indispensable. It is by far the best remedy in *cholera morbus*. No evacuant medicines need be first administered. A grain of opium should be given every half hour in severe cases, the patient refraining from the use of liquids as much as possible. Enemata of laudanum should also be employed; or the treatment may be confided to the hypodermic use of morphia. Care should be taken not to exceed the needful quantity of the drug administered, on account of the depression which is apt to follow the use of large doses. In *epidemic cholera*, depending as it does upon a specific poison, opium cannot be as confidently relied upon; indeed the records of its use in this disease are extremely discouraging. But in the forming stage, or that of premonitory diarrhœa, when that stage exists, opium with chalk and vegetable astringents is invaluable. The tender age and great susceptibility to the influence of opium of the ordinary subjects of *cholera infantum* render opium an unsafe remedy for that affection, notwithstanding the apparently clear indications for its use in the nature of the disease. If used at all it should be in the form of Dover's powder alone, or along with gray powder, or calomel. The symptom *colic*, as a form of pain, is of course amenable to a treatment by opiates, but it is a symptom connected with very numerous and dissimilar conditions. In the ordinary form due to flatulent distension of the bowel, opium with diffusible or carminative stimulants affords prompt relief. In *painter's colic*, which is attended with intestinal contraction and spasm, opium is the best remedy, especially in alternation with purgatives. *Biliary* and *nephritic colic* are most efficiently treated by opium; and when the pain arises from any of the various forms of intestinal displacement (*invagination*, *hernia*), the moderate but sustained use of opiates is infinitely preferable to the too common method of attempting to force an evacuation by means of purgatives. In all of these cases the hypodermic use of morphia is preferable to opium internally. Of the several forms of *peritonitis* those only which are due to traumatic causes, such as external violence and perforation or irritation of the peritoneum by diseases of the organs which it covers, are favorably influenced by opium; but in these it is indispensable, for by its means alone can that repose of the abdominal organs be secured which is necessary to control the degree and extent of the inflammation. In *puerperal peritonitis*, although it has been employed in heroic doses and emphatically praised, it has not been generally recognized as appropriate.

Among diseases of the genito-urinary organs opium is an efficient palliative in *nephritic colic*, already referred to, and in all the spasmodic affections of the *ureters*, *bladder*, and *urethra*, such as arise during calculous disorders, and inflammation of these several parts. Thus it is a usual remedy for *chordee*, although generally associated with camphor. In all these cases it is best administered by the rectum. It is an efficient palliative for the *grinding pains* which precede actual labor, and for those uterine contractions which so often lead to *abortion* or premature labor. Hypodermic morphia injections are more efficient than opium in such cases. The same means are frequently employed in *dysmenorrhœa*. In these various affections, and in all others within the pelvis for which opium is appropriate, suppositories containing this drug or its derivatives, and enemata with laudanum are especially indicated. In constitutional *syphilis* opium has been erroneously represented as a means of cure. It only allays constitutional irritability and procures rest from nocturnal pains. In the primary forms of the disease it is useful as a dressing for irritable sores. Opium is superior to any other single medicine in diminishing the quantity and the saccharine quality of the urine in *diabetes*, when administered in full and progressively increasing doses until a partial tolerance of the drug is induced. At the same time it lessens the thirst and hunger, renders the skin softer, and the mind less despondent. Its most efficient coadjutors are exercise and appropriate food.

Muscular rheumatism may generally be relieved by opium used so as to produce free diaphoresis, and especially in the form of Dover's powder. It is much more efficient in the forming stage of the attack than later. In *articular rheumatism* it has sometimes been used as an exclusive treatment, but with very unfavorable results, in that it augments the frequency and the gravity of the cardiac complications. It is, however, valuable as an anodyne and soporific, thereby husbanding the patient's strength while the disease is removed by eliminative medicines. In the same manner it is useful in *gout*, and particularly its liquid preparations. When this disease becomes *retrocedent*, and especially when it attacks the stomach, opiates associated with diffusible stimulants are the most reliable remedies. Wine of opium or laudanum should then be administered in doses of from forty to sixty drops every hour, by the mouth or rectum; or morphia may be employed hypodermically.

As a *local remedy* opium has already been noticed in connection with various painful affections; the uses of morphia in this respect are even more numerous. But the liquid preparations of opium in liniments, epithems, poultices, etc., as topical anodynes, are more habitually employed. A watery solution is used as a dressing for irritable *ulcers;* the wine of opium is an admirable anodyne and stimulant in granular *conjunctivitis* and *ulcers of the cornea;* in *earache* laudanum and sweet oil are applied on cotton to the auditory canal; in *toothache* a small piece of opium may be introduced into the hollow of a carious tooth, or, still better, a solution of morphia in chloroform, saturating a plug of cotton, may be similarly applied; or, in rheumatic toothache, the gums may be bathed with laudanum. In *paronychia*, and numerous other forms of painful local inflammation, the anodyne operation of opium and its preparations lessens the inflammation by assuaging the pain.

There is no specific antidote to *poisoning by opium*. The rational and habitual method of treating it consists in emptying the stomach of whatever portion it still contains of the poison, and in keeping the nervous system stimulated and the respiratory apparatus active, and so preventing or diminishing narcotism, until the poison is eliminated from the system. For the first purpose emetics are indicated, *e. g.*, large draughts of warm salt and water, mustard water, or water containing ipecacuanha, sulphate of zinc, or sulphate of copper. Tartar emetic should never be prescribed, unless other evacuants fail. It has been successfully employed by the rectum and also by the veins. Vomiting should be favored by tickling the fauces. If these means are not promptly and completely efficient, the stomach-pump should be resorted to. When solid opium has been taken, which, however, is rarely the case, the stomach-pump is of secondary importance. To counteract narcotism, stimulants of the general nervous system and of the respiratory apparatus are employed, both internally and externally. One of the best, as well as the most accessible, is a strong infusion of coffee, given without sugar or cream, but with a small proportion of brandy or whiskey. A strong infusion of green tea is nearly as efficient. The mydriatics (belladonna and stramonium) have been employed as direct antidotes. Their value is estimated in the articles devoted to those medicines. Of external means for stimulating the nervous system, one of the best is to cause the patient to walk, as long as he is able, supported between two assistants, while his attention is kept aroused by conversation, or by flagellating the back with a whip of fine cords or a bundle of birch twigs. Unless the impression made is sharp, it is almost useless. Hence the electrical brush answers remarkably well for this purpose. Cold, or alternate hot and cold, affusions, made to the upper part of the body, produce a powerful impression, and excite the respiratory act. The partial restoration of consciousness by these means is sometimes accompanied by a renewal of the susceptibility of the stomach, and the emetics it may contain excite vomiting. Ammonia may be held to the nostrils occasionally, and mustard applied over the epigastrium and heart; but the irritation produced by these agents makes it necessary to watch their action. Artificial respiration, although inferior to the other means described, has occasionally been used with success. In infants the natural resiliency of the ribs renders this agency especially useful.

The cure of *opium eating* consists either in gradually diminishing the quantity of the drug consumed, and the substitution for it of aromatic and stimulant tonics, such as ginger, black pepper, columbo, quassia, etc., or in the abrupt cessation of the practice. Both methods count a few successful cases; but the latter, while the more efficient, is the more arduous. In certain inveterate cases it is claimed that a cure has been effected by prescribing forty minims of dilute phosphoric acid and eighty minims of tincture of lupulin an hour before meals, in a wineglassful of water. At night sleep may be promoted by tincture of cannabis and Hoffmann's anodyne. The exhausted digestive function should be allowed to revive under simple food, such as milk and rich broths, in small quantities at a time. Exercise and bathing should be insisted upon, and zinc, quinia, and iron may be cautiously administered.

Administration.—The average *dose* of opium for an adult is one grain. This is usually an objectionable form of its administration, when the medicine must be repeated. In that case a liquid preparation should always be preferred. When a gradual operation is intended, an old opium pill is the best, since its slow solution prolongs its action and extends its local influence over a larger surface. It is also much less apt than freshly made opium pills to occasion nausea. The after effects of opium are supposed to be mitigated by bromide of potassium in a full dose administered along with the opiate. This apparent operation is rather due to the fact that with a full dose of the bromide, a smaller one of opium is necessary. Owing to the extreme susceptibility of children to opium, it should rarely be prescribed for them in the solid form. Suppositories of opium for the rectum and vagina are very useful in local disorders of the pelvic organs; and the rectal forms may also be used when for any reason the drug cannot be administered by the mouth. But they are less prompt in action than enemata of liquid opiates.

OPOPANAX.—OPOPANAX.

A gum-resin, obtained from Opopanax chironium, *Koch*, s. Pastinaca opopanax, *Lin.*

Nat. Ord.—Umbelliferæ, Orthospermæ.

Origin.—The opopanax plant is a perennial herb, with a long thick and fleshy root, a tall stem, large pinnately decompound leaves, yellow flowers, and dorsally flattened fruit containing many oil tubes. It is indigenous to Southern Europe. On wounding the root or lower part of the stem, a yellowish milk-juice exudes, which, after hardening, constitutes opopanax.

Description.—The best quality of opopanax is in irregular angular or subglobular pieces, from the size of a pea to that of a walnut, red-brown or yellowish-brown, friable, breaking with a flat somewhat waxy fracture, and frequently with vegetable fragments adhering. It has a strong, unpleasant odor, a balsamic bitter taste, yields with water a yellowish emulsion, and when heated, softens and exhales a rather alliaceous odor. An inferior quality comes in larger irregular masses, which contain many impurities, and are of a less bitter taste.

Composition.—According to Pelletier, opopanax contains 42 per cent. resin, 33.4 per cent. gum, besides volatile oil, a little wax, starch, etc.

Allied Gum-Resins.—SAGAPENUM, obtained from a Persian species of Ferula, is met with in yellowish-brown, somewhat translucent small tears, and is frequently agglutinated to larger pieces, of a bitter acrid taste and a faint alliaceous odor, which becomes prominent on heating. Cake sagapenum is soft, adhesive, brown, nearly free from tears, mixed with foreign matters. A mixture of galbanum and asafœtida is sometimes sold in place of sagapenum. Pelletier and Brandes found in sagapenum 50 to 54 per cent. of resin, 32 per cent. gum, with small quantities of volatile oil, bassorin, etc.

GUMMIRESINA HEDERÆ, *ivy gum*, is in the Levant and Southern Europe obtained from the common ivy, Hedera helix, *Lin.* It is in irregular yellowish or reddish-brown pieces, translucent on the edges with a garnet-red color, of a slightly bitter and somewhat acrid taste, and when heated of an agreeable balsamic odor. Pelletier found in a sample nearly 70 per cent. of wood fibre.

Medical Action and Uses.—Opopanax (the all-healing juice) is one of the numerous gum-resins, including galbanum and ammoniac, which were anciently most esteemed. Galen speaks of it and of the root-bark of the plant as stimulating and cleansing when applied to ulcers, and of the seeds as diuretic. Dioscorides describes its internal uses in fever and ague, pleurisy, cough, dysury, and amenorrhœa, and its topical applications in sprains, headache, gout, toothache, and carbuncle. Arabian writers advise it in nervous exhaustion, for promoting the expulsion of the dead fœtus, for paralysis, and inflammation of the eyes. In modern times, it has been used like ammoniac, for *chronic bronchitis* with profuse secretion, and externally in stimulating plasters, but is now very seldom employed.

ORIGANUM, *U. S.*—ORIGANUM.

Origan, Marjolaine sauvage, Fr.; *Dosten, Wilder Majoran*, G.

The herb of Origanum vulgare, *Lin.* Bentley and Trimen, Med. Plants, 204.

Nat. Ord.—Labiatæ, Satureieæ.

Origin and Description.—Origanum or *wild marjoram* is a perennial herb, growing in dry soil throughout a large portion of Asia, Europe, and Northern Africa. It has been introduced into the United States, where in some places it is now quite common. The stem is about two feet high, quadrangular, often purplish, branched above. The leaves are opposite, petiolate, roundish ovate, obtuse, entire, or slightly toothed, hairy on the veins beneath, and pellucid punctate. The flowers are terminal on the branches, forming a corymbose panicle, have a purple, ovate bell-shaped and five-toothed calyx, a purplish somewhat two-lipped corolla, and four didynamous exserted stamens. The herb has a strong aromatic, marjoram-like odor, and a warm aromatic and bitterish taste.

Constituents.—The herb contains volatile oil (see Oleum origani, p. 986), a little tannin, bitter principle, etc.

Allied Plants.—ORIGANUM MAJORANA, *Lin.*, s. Majorana hortensis, *Mœnch*, *Sweet marjoram*, is frequently cultivated for culinary purposes, and is indigenous to Western Asia and Southeastern Europe. The leaves are spatulate or oval, very obtuse, entire, gray-green, soft, hairy, and pellucid punctate. The flowers are aggregated in small heads, and have a small whitish corolla. The plant is agreeably and pungently aromatic.

ORIG. CRETICUM, *Lin.*, indigenous to Southern Europe, has hairy ovate or nearly cordate and somewhat five-nerved, pungently aromatic leaves, and whitish flowers. In Europe, the volatile oil is distilled from it, and is used like allied oils.

ORIG. DICTAMNUS, *Lin.*, is found in the Levant, has woolly-tomentose, obtusely quadrangular branches; roundish-ovate tomentose leaves, partly purple-colored bracts, and a dark purplish corolla. It is pungently aromatic.

Medical Action and Uses.—Marjoram is chiefly used as a condiment in cooking, to diminish, by its excitant qualities, the indigestibility of pork, goose, and other fatty food. It is sometimes employed in warm infusion to promote the eruption in exanthematous fevers, allay *colic*, *dysmenorrhœal pains*, etc., and the fresh bruised herb is applied as a cataplasm to assuage local pains.

OS, *U. S.*—BONE.

Os, Fr.; *Knochen*, G.

Description.—Bones form the skeleton of the vertebrate animals, and consist of a dense organic tissue, which is filled with a calcareous deposit. They are white, externally smooth, insoluble in water, partly soluble in acids, leaving a gelatinous mass behind, and when heated, are partly decomposed, an empyreumatic animal odor being given off and a porous charcoal left (Carbo animalis, p. 345). On continuing the heat in contact with air, the organic matter is entirely consumed and a white earthy residue remains.

Composition.—The organic portion of bones which is left undissolved on treatment with hydrochloric acid, has been called *ossein*, and on continued boiling with water is converted into gelatin (see p. 661). The inorganic portion varies in different bones of the same individual, and in the bones of different species, and in different layers of the same bone; it is smaller in the inner layers, amounting sometimes to 40 per cent., and in the outer layers it may reach 67 per cent. The ash contains phosphate (usually about 57 per cent. of the bones) and carbonate (about 5 to 10 per cent.) of calcium, phosphate of magnesium (1.1 to 2.7 per cent.), fluoride of calcium (nearly 1 per cent.), and traces of silica, iron, manganese, and probably also sodium chloride. Æby (1874) considers the principal inorganic constituents of bones to be united to a chemical compound having the formula $3(Ca_32PO_4).CaCO_3$, probably united with water and mixed with calcium carbonate. Ivory, including the fossil kind, has the composition $6(Ca_32PO_4).Ca2HO.CaCO_3.4H_2O$. When old bones free from organic matter are dried at 200° C. (392° F.), the residue, on being moistened with water, becomes warm and increases to its original weight again. Above 250° C. (482° F.), more water and carbonic acid are given off.

Pharmaceutical Uses. Os ustum, *Br.*—Bone ash is the inorganic residue left on burning bones to whiteness, and consists principally of phosphate of calcium with about 10 per cent. of carbonate of calcium and a little calcium fluoride and magnesium phosphate. It is used in the manufacture of glacial phosphoric acid, and in preparing Calc. phosphas and Sod. phosphas, *U. S.*, *Br.*

OVUM, *U. S.*—Egg.

Œuf, Fr.; *Ei*, G.

The egg of Phasianus gallus, *Lin.*, s. Phas. banckiva, var. domesticus, *Temminck.* *Class* Aves. *Order* Gallinæ.

Origin and Description.—The domestic fowl is regarded as having originated from the Javan fowl, *G. banckiva.* At the present time numerous varieties of it are found in all civilized countries. The eggs, which are the part employed for pharmaceutical and medical purposes, consist of the shell and lining membrane 10.7 parts, albumen 60.4 parts, and yelk 28.9 parts (Prout, 1822).

Composition.—1. Egg-shell, *Testa ovi*, consists, according to Prout, of 97 parts calcium carbonate, 1 part calcium and magnesium phosphates, and 2 parts organic matter. Vauquelin's results were 89.6, 5.7, and 4.7 respectively.

2. White of egg, *Albumen ovi*, Br.—It consists of 2 or 3 laminæ, the total average weight being 23.01 grms. (Lehmann), or 24.8 grms. (Poleck), and contains 82 to 88 per cent. water, and on the average 13.32 solid constituents, including 0.65 ash, as well as minute traces of fat, sugar, and extractive. The ash of the egg albumen consists of 42 per cent. chloride of potassium, 9 of chloride of sodium, 12 of carbonic acid, the remainder being phosphates and sulphates of the alkalies, silica, iron, lime, and magnesia. The organic portion of the white, the *albumen* proper, is a protein compound; the average elementary composition is 53.7 C, 15.5 N, 7.1 H, 22.1 O, and 1.6 S. Its aqueous solution rotates the plane of polarized light to the left, may be evaporated in thin layers below 50° C. (122° F.) without change, but on being heated to near 75° C. (167° F.) it is coagulated and becomes insoluble in water. Albumen is precipitated from its solutions by most mineral and by some organic acids, but not by phosphoric or acetic acid. It is soluble in caustic alkalies, and precipitates the salts of most heavy metals, hence its value in cases of poisoning by salts of mercury, copper, etc. Albumen is also precipitated by volatile oils, camphor, and by tannin, the last precipitate being soluble in an aqueous solution of tannin. Alcohol coagulates albumen, and ether precipitates it, the precipitate being only partially soluble in water. Farsky (1878) has succeeded in obtaining what appears to be a definite compound of salicylic acid with albumen, by stirring the two together for some time, washing with ether and hot water, and drying in an air-bath at about 120° C. (248° F.); it was found to contain 14.16 per cent. of salicylic acid and 85.84 of albumen, and to be as easily digestible as the uncombined albumen. When boiled with *Millon's reagent* (mercury dissolved in an equal weight of warm nitric acid, and the solution diluted with twice its bulk of water, and decanted from the precipitate), the precipitate as well as the liquid turns red. Other protein compounds show a like behavior.

3. Yelk of egg, *Ovi vitellus*, Br.—The *yelk* is a viscid yellow or reddish-yellow opaque liquid, which is without odor, has a bland taste, an alkaline reaction, and must be regarded as a dense emulsion consisting of oil suspended in water by means of albumen. When triturated with water, a whitish emulsion is obtained; the addition of alcohol causes it to coagulate, and when agitated with ether, it separates a white mass and yields to ether an orange-yellow fat. Yelk is coagulated by heat. It contains 48 to 55 per cent. of water, 16 to 18 per cent. of *vitellin*, which is probably a proteid closely related to casein, and

mixed with about one-fourth of albumen; 29 to 31 per cent. of fat, 21.3 parts of which are olein and margarin, according to Gubley; 1.5 per cent. inorganic salts, coloring matter, a small portion of sugar, and 0.42 of cholesterin. Gubley has separated from the ethereal extract of yelk a substance, which he named *lecithin*, and is evidently a mixture; it is said to contain *oleophosphoric acid*, which under some conditions yields oleic and *phosphoglyceric acids*.

Preservation.—Eggs may be preserved for a considerable length of time by covering the shell with a substance impervious to water, and closing the pores so as to exclude the air. This may be done by wax, fat, paraffin, gum, or by similar substances. Packing them with the small end downward in dry salt, milk of lime, etc., has likewise been recommended.

Pharmaceutical Uses.—The white of egg is used for the clarification of syrups, honey, and other liquids. The yelk is employed in emulsionizing fixed and volatile oils and in preparing Mistura chloroformi, *U. S.*, and Mist. spir. vini gallici, *Br.*

Medical Action and Uses.—*Egg-shells* were long used for the various purposes to which chalk is now applied internally. Like crab's eyes and claws, corals and oyster-shells, which were formerly employed, they contain a certain proportion of animal matter which mitigates the action of the calcareous constituent. They were an ingredient of a secret remedy for *gravel*, for a knowledge of which the British Parliament paid an extravagant sum of money. The *white of egg* forms with solutions of corrosive sublimate and of sulphate of copper compounds which are nearly insoluble, and hence it has been used in *poisoning* with these salts, first to neutralize and then to evacuate them. Its demulcent and protective action is also advantageous. It is applied in the treatment of *burns* and *erysipelas*, either alone or emulsified with oil, or coagulated by alum in the form of alum curd. The latter is an excellent application in acute *conjunctivitis*. Diluted with water, sweetened, and flavored, it forms an agreeable and useful drink in numerous cases of *gastro-intestinal* inflammation and irritation. Albumen is sometimes used as a substitute for starch in the application of fixed *bandages*. The *yelk of egg* is more nutritious and digestible than the white, and is habitually employed whenever it is desired to give the largest amount of nutriment in a small bulk, and in the most digestible form. The yelk of a hard-boiled fresh egg readily crumbles, and is, therefore, easily acted upon by the gastric juice. The fresh yelk, beaten with sugar, and mixed with hot water, and with the addition of a little brandy and nutmeg or cloves, forms a customary draught at the commencement of catarrhal and rheumatic (muscular) affections. It is used also to form emulsions for the administration of castor oil, cod-liver oil, oil of turpentine, etc., either by the mouth or the rectum. Externally, it is sometimes, and very usefully, employed as a dressing for *burns*, *scalds*, *abrasions*, etc., and to soften the crusts of *cutaneous eruptions*, *cerumen* in the auditory canal, etc.

OXALIS.—Wood-sorrel.

Alléluia, *Surelle*, *Pain de coucou*, Fr.; *Sauerklee*, *Hasenklee*, G.

Nat. Ord.—Geraniaceæ, Oxalideæ.

Description.—The following species indigenous to North America and Europe have been used:—

O. acetosella, *Lin.*—The plant has a thin thread-like rhizome, which, near the ascending apex, is furnished with a number of crowded reddish fleshy scales and fine brown radicles. The leaves rise upon petioles about two and a half inches long, and have three triangular-obcordate entire leaflets, half an inch long. The scapes are longer than the petioles, and bear a single white, red-veined flower, with ten alternately short stamens. The capsule is five-angled and five-celled, each containing two seeds.

O. stricta, *Lin.*—This is an annual herb, with a stem six to twelve inches high, producing subterranean shoots which survive the winter. The leaves are petiolate, with three obcordate leaflets, and the flowers yellow, forming a small umbel on peduncles longer than the petioles.

Several species, mostly acaulescent and bulbous, and bearing white, purple or yellow flowers, are seen in cultivation. All are inodorous, or nearly so, and have a pleasant acidulous taste.

Constituents.—Besides the principles common to most herbs, these plants contain acid potassium oxalate (see p. 64).

Medical Action and Uses.—Wood-sorrel and yellow wood-sorrel depend for their medicinal virtues upon the oxalate of potassium they contain. They have long been considered antiscorbutic, diuretic, and sedative in febrile conditions. In the last case an infusion of the plant forms an agreeable acidulous fever drink. Sorrel may be eaten as a salad mixed with lettuce, water-cress, etc. In *scurvy*, *purpura*, and some cases of vernal *intermittent fever*, it is reported to have been curative. In Europe it is commonly eaten as a dressing for insipid meats, such as veal and sweet-breads; and it is stated that its habitual use in this way has led to the formation of urinary calculi of oxalate of lime. Externally, the bruised leaves are sometimes applied to cleanse and stimulate foul *ulcers*.

OXYGENIUM.—OXYGEN.

Oxygène, Fr.; *Oxygen*, G.
Symbol O. Atomicity bivalent. Atomic weight 16.

Oxygen was discovered by Priestley (1774) and Scheele (1775). It constitutes about one-fifth of the volume of atmospheric air, the remainder being nitrogen, with a small proportion of carbonic acid gas. Eight-ninths of the weight of water, and one-half the weight of many minerals consist of oxygen, and it is estimated that at least one-third the weight of the solid crust of the earth is made up of this element, which is the most abundant of all.

Preparation.—Oxygen may be obtained by exposing binoxide of manganese, oxide of mercury, or some other metallic oxides, to a strong heat; but it is most conveniently prepared by heating a mixture of four or five parts of chlorate of potassium with one part of binoxide of manganese. At a low red heat the chlorate is completely decomposed into oxygen and potassium chloride, which remains mixed with the manganese; the latter, not being altered, may be recovered by dissolving the potassium chloride in water; $KClO_3$ yields $KCl + O_3$. Care should be taken that black sulphuret of antimony be not used in place of binoxide of manganese, since a violent explosion would take place on the application of heat.

Properties.—Oxygen is a colorless and inodorous gas, having the density 1.1056 as compared with air; one liter of it, at 0° C. (32° F.), and a barometric pressure of 0.76 meter, weighs 1.4303 gram. L. Cailletet and R. Pictet (December, 1877) succeeded in reducing it to the liquid state, when it has the density 1.0. It is slightly soluble in water and alcohol, and combines with all other elements, perhaps with the sole exception of fluorine. These compounds are called *oxides*, and the act of combination *oxidation*, and when attended with heat and light, it is termed *combustion*.

By the action of electricity upon oxygen, or by the slow oxidation of phosphorus in moist air and under various other circumstances, oxygen is converted into *ozone*, which is a colorless gas, of a peculiar odor, somewhat resembling that of chlorine. It is a powerful oxidizing agent, bleaches indigo solution, and liberates iodine from potassium iodide; paper dipped in thin starch paste containing potassium iodide is turned blue by ozonized air, and is a delicate test for the presence of ozone. This body has not been obtained free from oxygen; it is regarded simply as a modification of oxygen, its formula being O_2O, indicating that three vols. have been condensed into two; its spec. gravity is one-half greater than that of oxygen. It is nearly insoluble in water (see also page 731).

Physiological Action.—It was taken for granted that oxygen could be introduced as readily as food is carried into the system through the stomach, and that by its means all the organic operations of the economy could be aroused to an increased activity. Experimenters graphically described the enlivening influence of this increased supply of "vital air" upon the sensations and the organic functions, and were apt at explaining how it not only must, but actually did, cure some of the gravest of diseases. But it was pointed out by Dr. A. H. Smith, and then by Dr. B. W. Richardson, that no more than a certain proportion of oxygen, such as exists in the atmosphere, can be absorbed by the lungs. Their results were subsequently (1875) confirmed by Buchheim, who concludes that "henceforth we must abandon the notion that the course of diseases can be modified by increasing the amount of oxygen in the blood."

Medical Uses.—A critical examination of the reports of *pulmonary consumption* treated by oxygen proves that no ground exists for the belief that the disease is either curable or benefited by this gas; the same may be said of *diabetes;* and it might be added, also, of chronic *bronchitis*, and other affections of the respiratory organs, were it not that in such of them as are attended with symptoms of *asphyxia*, the inhalation of oxygen has certainly appeared to prolong and even to save life. This has been demonstrated in asphyxia from emphysema with bronchitis, in laryngitis of various forms, in compression of the lungs by the gravid uterus, in opiate narcotism, in poisoning by charcoal fumes or by illuminating gas, and in similar conditions. If possible, it should be inhaled from a reservoir or bag containing it, through a tube with a suitable stopcock and valves, as in the case of nitrous oxide gas.

OXYMEL, *Br.*—Oxymel.

Oxymel simplex, P. G.; *Mel acetatum.*—*Oxymellite simple, Acétomel*, Fr.; *Sauerhonig*, G.

Preparation.—Take of Clarified Honey forty ounces; Acetic Acid and Distilled Water each five fluidounces. Liquefy the honey by heat, and mix with it the acetic acid and water. *Br.*

The French Codex orders one part of white wine vinegar to be mixed with four parts of virgin honey, and the mixture to be concentrated and clarified with paper pulp. The German Pharmacopœia directs the mixing of forty parts of clarified honey with one part of acetic acid spec. grav. 1.040; this is certainly the simplest process.

Medical Action and Uses.—This is an officinal form of the popular mixture of honey and vinegar, which is generally used as a gargle in *sore throat.* It may be prescribed as an excipient for various expectorant medicines, and particularly of squill and ipecacuanha in the form of syrup.

OXYMEL SCILLÆ, *Br.*—Oxymel of Squill.

Preparation.—Take of Vinegar of Squill one pint; Clarified Honey two pounds. Mix and evaporate by a water-bath until the product when cold shall have a specific gravity 1.32. *Br.*

Medical Action and Uses.—Oxymel of squill has the medicinal virtues of syrup of squill, neither more nor less. Honey is superior to syrup as a local application to the throat; but there is no known difference between them in their action upon the air-passages. Like the syrup of squill, the oxymel may be prescribed in *catarrhal affections* of the respiratory mucous membrane, and in young children as an emetic in spasmodic *croup*. The *dose*, as an expectorant, is for adults a teaspoonful; for infants from five to twenty drops. As an emetic for children, a teaspoonful may be given at short intervals.

PÆONIA.—PEONY.

Pivoine, Fr.; *Gichtrose*, *Pfingstrose*, G.

Pæonia officinalis, *Lin.* *Nat. Ord.*—Ranunculaceæ, Pæonieæ.

Description.—Peony is a perennial herb from Southern Europe, which is frequently cultivated for ornament. It has an oblique many-headed root-stock, six or nine inches in length, with numerous at first fibrous *roots*, which afterwards enlarge and become fusiform, dark-brown, internally white and mealy, resembling elongated tubers. In commerce, these are generally peeled, are whitish or purplish, and have near the circumference narrow yellow wood wedges. The branched stem is about two feet high, smooth, with large, twice or thrice pinnately dissected and cleft green smooth leaves, and large terminal flowers, having five sepals, five to eight petals, numerous stamens, and two to five ovaries. The *petals* are obovate, entire or crenate, one and a half inch long, dark-red, purple or rose-red, after drying inodorous, and have a sweetish astringent taste. The *seeds* are nearly globular, one-eighth to one-sixth of an inch in diameter, black, glossy, and smooth, inodorous, and contain a yellowish oily albumen and a small embryo. The tuberous roots, petals, and seeds have been used.

Constituents.—Wiggers obtained from the fresh root a distillate having the odor of bitter almonds, and acquiring a blood-red color by ferric chloride; separated by means of ether, the volatile oil had a pale yellow color. The analysis of the fresh root by Morin proved the presence of starch, sugar, fat, malates, oxalates, and phosphates, a little tannin, etc.

Medical Action and Uses.—In the ages of medical faith the virtues of this plant were highly esteemed. Galen described its acrid qualities and emmenagogue virtues, and its astringency, also, which rendered it useful in diarrhœa. A superstition prevailed in his time that peony root inclosed in a bag and hung around a child's neck both prevented epileptic attacks and cured them, and the belief is not extinct among the peasantry of Europe even now. They also believe that the same amulet, or rather one made with the seeds, worn on the arm will prevent the dangers of dentition, and promote menstruation. That the plant is not inert is abundantly proved; its very odor has caused syncope; in one case an infusion of it brought on an attack of convulsions, and in another it produced headache, ringing in the ears, confusion of sight, violent colic, and vomiting. Modern observation has neither confirmed nor condemned the ancient opinions concerning this plant; and although some have reported favorably of it in epilepsy, chorea, and whooping cough, the evidence in favor of its efficacy is very slender indeed.

PANAX, *U. S.*—GINSENG.

The root of Panax quinquefolium, *Lin.*, s. Aralia quinquefolia, *Gray*. *Nat. Ord.*—Araliaceæ.

Origin.—The North American ginseng is a perennial herb growing in rich and cool woods. The stem is a foot high, and bears at the summit three large palmately five-foliate leaves, with long-stalked, obovate-oblong, pointed, doubly serrate leaflets. The greenish-white flowers are in a terminal subglobular umbel, and produce globular scarlet red two-celled and two-seeded berries.

Description.—The root is fusiform, two to three inches long, with a rounded head, closely annulate, and with few wrinkles above; then dividing into two or occasionally three branches of even size. The branches are not, or are but slightly, annulate, and longitudinally wrinkled. The root is externally of a light brownish-yellow color, internally white, breaks with a short and mealy fracture, and has a faint sweetish odor and a sweet slightly aromatic taste. The transverse section shows a thick bark, with numerous scattered brown-red resin cells, and in older roots radially striate from the bast wedges; it is separated by a brown cambium line from the central portion, which consists of linear wedge-shaped yellowish wood bundles and broad medullary rays.

Panax schinseng, *Nees*, the *Chinese ginseng*, has a larger root, four to six inches long, darker in color, and near the head usually with two lateral branches, otherwise resembling the preceding.

Constituents.—Besides starch, gum, albumen, and resin, S. S. Garrigues (1854) isolated a sweet principle, *panaquilon*, $C_{12}H_{25}O_9$, by adding to the syrupy infusion a concentrated solution of sodium-sulphate and dissolving the precipitate in alcohol. It is yellow, amorphous, sweet, insoluble in ether, and precipitated by tannin. Concentrated sulphuric acid dissolves it with a purple-red color, converting it at the same time into *panacon*, $C_{11}H_{19}O_4$, which is white, tasteless, and insoluble in water and ether, but soluble in alcohol.

Medical Action and Uses.—It is unsettled whether or not the American and Chinese species of ginseng are identical. It is, at least, certain that while the former is only agreeable in taste and perhaps useful as a mild stomachic, the latter enjoys in its native country the reputation of a panacea. The affections for whose cure it is most esteemed are such as are usually treated by aromatic stimulants, including *dyspepsia, vomiting, and nervous disorder.* It appears to be a superfluous member of the Pharmacopœia.

PANCREATINUM.—PANCREATIN.

Origin.—The *pancreas* is a gland which is deeply seated in the abdomen, and secretes the *pancreatic juice*, containing the proteid *pancreatin*, to which it owes the property of emulsifying and decomposing fats into glycerin and acid, and of converting starch into sugar. The pancreatic juice is a colorless, clear, somewhat viscid liquid, of an alkaline reaction, and without odor and taste; it contains, besides the ferment, nearly one per cent. of mineral salts, a trace of fat and of organic matters soluble in water.

Preparation.—Prof. Scheffer (1875) recommended the following process: Fresh and finely chopped beef pancreas is macerated for a day in water acidulated with a little muriatic acid; the maceration is repeated with water, the strained liquids filtered, neutralized with calcium carbonate, again filtered, and mixed with an equal volume of 95 per cent. alcohol; the precipitate is washed with dilute alcohol, pressed between bibulous paper, and dried at the ordinary temperature.

Properties.—Thus prepared it is a transparent, brittle, yellow mass, which dissolves in water slowly, but almost entirely, leaving, when prepared in cold weather, only a trace of insoluble matter. The solution is clear, pale yellowish, neutral, and produces white precipitates on heating and on being mixed with alcohol. Muriatic acid likewise precipitates it, but not a saturated neutral solution of table salt.

Composition.—Like other proteids, pancreatin consists of C, H, N, O, and a little S (see Ovum, p. 1027). Bernard assumed the presence in the pancreatic liquid of two ferments, and recently (1878) Defresne announced the isolation of even three, namely, *myopsin*, which digests albumen; *amylopsin*, which saccharifies starch; and *steapsin*, which decomposes fats.

Medical Action and Uses.—The pancreatic juice has the power of forming an emulsion with fatty food, which fits it for absorption and nutrition. It has a digestive action upon starchy aliment. During the first years ot life, when the food consists chiefly of milk and farinacea, a state of *dyspepsia* frequently arises, which often leads to marasmus, and which is not traceable to any organic lesions of the stomach or auxiliary viscera. In this it is claimed that pancreatic emulsion speedily restores the digestive function to its normal condition, and, through improved nutrition, renews the health. In this way also, in certain cases of fatty diarrhœa, is said to have rendered the stools natural and restored the wasted flesh. A few clinical reports of the utility of this preparation, which do not appear to have been corroborated by general experience, have been followed by an apparent oblivion of the whole subject.

PAPAVER, *U. S.*—POPPY.

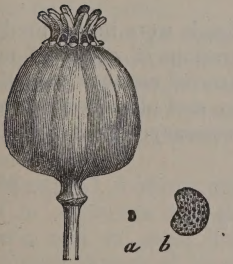
Papaveris capsulæ, Br.; *Fructus s. Capita papaveris*, P. G.—*Poppy capsules*, E.; *Capsules* (*Têtes*) *de pavots*, Fr.; *Mohnkapseln*, *Mohnköpfe*, G.

The nearly ripe capsules of Papaver somniferum, *Lin.*

Nat. Ord.—Papaveraceæ.

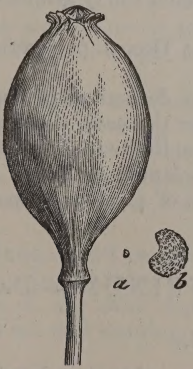
Origin.—The poppy is most likely indigenous to Western Asia and Southeastern Europe, where it is found wild in fields and waste places. It is frequently cultivated in gardens for ornament, and very extensively in several countries for the production of opium (see page 1009). The stem is three or four feet high; the leaves are alternate, five to ten inches long, oval-oblong, sessile, and the upper ones clasping, irregularly dentate, frequently cleft or nearly pinnatifid, rather thick, smooth, and glaucous. The flowers terminate the branches, are about four inches broad, and have two oval blunt sepals, and four broad roundish petals varying in color from white to violet and dark purple, with a darker spot near the base. The stamens are very numerous, and inserted beneath the subglobular ovary, which is crowned by the peltate radiating stigma. The wild form, Papaver setigerum, *D. C.*, has acute teeth, prolonged into a stiff bristle. The white flowering variety, Pap. officinale, *Gmelin*, has white seeds, and its capsules are alone recognized by the British Pharmacopœia.

Fig. 125.



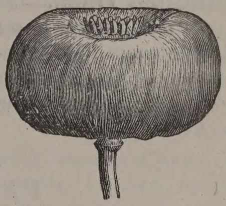
Black.

Fig. 126.



White.

Fig. 127.



Depressed.

Poppy capsules and seeds (*a*, natural size; *b*, magnified).

Description.—Poppy capsules vary in shape and size according to the variety of the plant from which they have been obtained. The black poppy usually has rather small capsules, which are globular-ovate, about an inch and a half in diameter, broadest near the base, and dehiscent by small apertures forming underneath the stigma. The capsules of the white poppy are mostly larger, indehiscent, and more variable, occasionally depressed, and much broader than high, but usually oblong, or in some varieties much elongated, and narrowed towards the base. The sessile and peltate stigma is formed of from eight to twenty rays; and a similar number of longitudinal striæ, marking the sutures, are observed upon the immature capsule, which is smooth, and underneath the epidermis consists of loose parenchyma with a circle of thin fibro-vascular bundles and larger laticiferous vessels. The capsule is one-celled, but internally is furnished with placentas equal in number to the lobes of the stigma, and projecting into the interior, forming incomplete partitions. In the fresh state it has a narcotic odor; after drying it is nearly inodorous; its taste is bitter.

SEMEN PAPAVERIS. Poppy seed, Maw seed, *E.;* Graines de pavot, *Fr.;* Mohnsamen, Magsamen, *G.*—The seeds are very numerous, quite small, about one-twentieth of an inch long, reniform in shape, white, blackish, or bluish, finely netted-veined, and contain an oily albumen, inclosing a curved embryo. They are inodorous, and have a bland oily and scarcely bitterish taste.

Constituents. 1. THE CAPSULES.—Winckler (1837), Merck, and others have demonstrated the presence of *morphia* in ripe poppy capsules; the former chemist obtained as much as two per cent. of this alkaloid and likewise *narcotina* and *narceia.* Groves (1854) found also another alkaloid, which was probably *codeia.* A. Buchner obtained an alkaloid which differed from morphia, and other chemists were unable to find the latter. Deschamps (1864) isolated an alkaloid, *papaverosina,* which crystallizes in prisms, and does not appear to neutralize acids completely; and silky needles of a nitrogenous body, called *papaverin,* which is said to have an acid reaction. Hesse (1866) obtained *rhœadina* from ripe poppy capsules. Besides meconic acid, which could not be detected by several chemists, citric and tartaric acids were found by Deschamps. The capsules contain considerable mucilage and a little waxy matter.

2. THE SEEDS.—Sacc (1849) obtained from white poppy seeds nearly 55 per cent. of fixed oil, 23 pectin, and 12.6 per cent. protein compounds. Accarie (1833) announced that he isolated thirty grains of morphia from six pounds of white seeds.

Off. Prep.—Of the capsules: Decoct. papaveris, Extract. papaveris, Syrupus papaveris, *Br.*

Medical Uses.—Formerly decoctions of poppy heads were much used internally; but such is no longer the case, since preparations of opium of more definite strength have become multiplied. Even for external use such decoctions have been almost entirely supplanted by liquid opiates and plasters containing opium. The officinal retention of papaver seems unnecessary, unless for pharmaceutical purposes.

PARAFFINUM.—PARAFFIN.

Paraffine, Fr.; *Paraffin,* G.

Origin.—The paraffins are produced under various circumstances from fats and other organic compounds, but are chiefly obtained among the products resulting from the destructive distillation of many organic substances, especially cannel and boghead coal. They are a natural constituent in varying proportions of the different kinds of petroleum, and the solid paraffins are found native in Austria and some other countries, constituting the minerals known as *earth-wax, fossil-wax,* and *ozokerite.*

Composition and Characters.—The general formula of the paraffins is the same as that of the lighter coal oils, C_nH_{2n+2}; but in their physical properties they differ from the latter in being at the ordinary temperature either solid, and frequently crystalline, or of an oleaginous consistence and liquid. Those which are liquid at the ordinary temperature are known in commerce as *paraffin oils*, while the name *paraffin* is retained for the solid products. They can be separated from one another only with great difficulty; but it is known that the different members of this homologous series increase in density, viscidity, and in boiling point, and the solid paraffins also in melting point and hardness, as the molecular weight increases. The paraffins obtained in as pure a state as possible show the following differences:—

Nonane (Nonylhydride)	C_9H_{20}	boils near	138° C.	= 280.4° F.	Spec. grav.	.741
Decane (Decatylhydride)	$C_{10}H_{22}$	"	160	= 320	"	.757
Endecane (Undecylhydride)	$C_{11}H_{24}$	"	180	= 356	"	.766
Dodecane (Laurylhydride)	$C_{12}H_{26}$	"	200	= 392	"	.778
Tridecane (Cocinylhydride)	$C_{13}H_{28}$	"	220	= 428	"	.796
Tetradecane (Myristylhydride)	$C_{14}H_{30}$	"	240	= 464	"	.809
Pentadecane (Benylhydride)	$C_{15}H_{32}$	"	260	= 500	"	.825

Galletly (1871) ascertained for paraffins—

Fusing at	32.0°	39.0°	40.5°	53.3°	58.0°	59.0°	80.0° C.
The spec. grav.	.8236	.8480	.8520	.9100	.9243	.9248	.9400

The solubility of paraffins in benzol decreases as the melting point rises, the last one of the table being nearly insoluble therein.

Paraffins are not easily acted on by chemicals; they are freed from hydrocarbons of the *olefin series*, C_nH_{2n}, by strong sulphuric acid, which destroys the latter. By continued boiling with nitric acid the higher paraffins yield nitro-compounds and various acids. Boiling muriatic acid or contact with chlorine gas, ammonia, or potassa has no effect upon paraffin; but the lowest members of the series, which are gaseous at the ordinary temperature, yield substitution products with chlorine.

Paraffin is insoluble in water, alkalies, and cold alcohol, but dissolves in volatile and fixed oils, ether, chloroform, benzol, and carbon bisulphide; the solubility is, however, influenced by the composition. In distilling paraffin, the heat to which the vapors are exposed influences the melting point, and consequently the composition; at a red heat *naphthalin* is produced, and when paraffin is heated for some time in a sealed tube it is split into an *olefin* and a paraffin of a lower boiling point.

J. L. Lemberger and A. W. Miller ascertained (1875) that crude paraffin oils may be deprived of their odor by filtering them through granulated animal charcoal. *Cosmoline*, *vaseline*, and other copyrighted preparations are paraffins of the consistence of ointments. The liquid paraffins are extensively employed for lubricating purposes, and are known in commerce as *lubricating oils* and *neutral oils*.

Medical Action and Uses.—Soft paraffin is much used in a pure state and in ointments as a dressing for *chilblains*, *excoriations*, *bruises*, *indolent ulcers*, and in some diseases of the skin, especially *psoriasis* and *scabies*. Authentic reports of its effects are still wanting.

PAREIRA, *U. S.*—PAREIRA BRAVA.

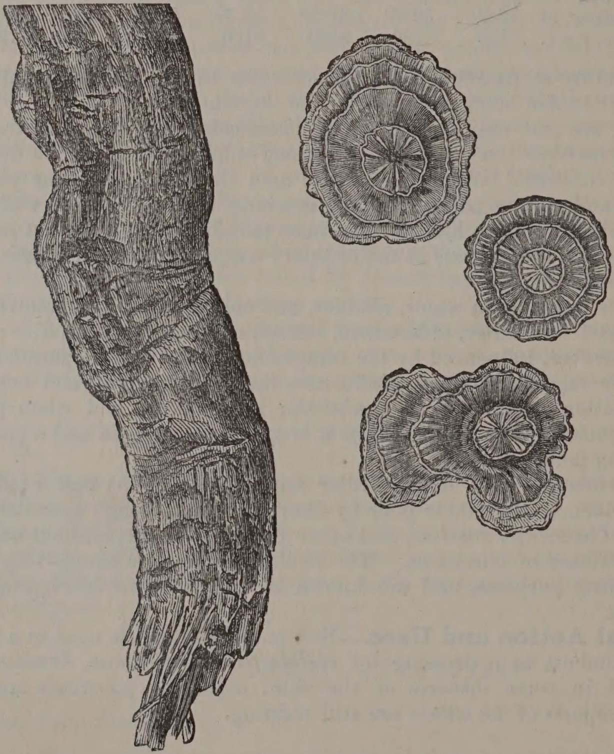
Pareiræ radix, Br.—*Pareira brava*, Fr., G.

The root of Chondodendron tomentosum, *Ruiz and Pavon*, s. Cocculus chondodendron, *D. C.*, s. Cissampelos abutua, *Vell.* Bentley and Trimen, Med. Plants, 11.

Nat. Ord.—Menispermaceæ.

Origin.—The United States and British Pharmacopœias refer pareira brava to Cissampelos pareira, *Lin.*, s. Ciss. microcarpa, *D. C.* (Bentley and Trimen, Med. Plants, 15), which is a woody climber, indigenous to the West Indies and Central America, and probably to other tropical countries. It is medicinally employed there, but is not exported. The root as well as the stem rarely reaches an inch in diameter, and is often not thicker than a goose-quill; both show no concentric rings in transverse section, the wood consisting of about 20 porous wedges, separated by narrower medullary rays, and covered by a gray-brown suberous bark.

Fig. 128.



Pareira brava. Portion of a root, and transverse sections of the same.

The true origin of pareira brava was established by Hanbury (1873), and is the species mentioned above. This is a tall woody climber of Brazil and Peru, having large cordate or ovate-cordate, somewhat five-nerved leaves, very small unisexual flowers and purplish-black ovoid one-seeded drupaceous fruits, which form thick bunches, resembling grapes in appearance.

Description.—Pareira brava comes to us in pieces, three to six inches long or even longer, and from about one to three inches in diameter, more or less tortuous, dark-brown or blackish externally, and marked with transverse ridges and fissures, and with irregular longitudinal furrows. Internally it is of a pale-brown color; when cut, exhibits a somewhat waxy lustre, and on breaking, shows a fibrous fracture. On transverse section are seen under a thin bark, two or more concentric zones separated by wavy circles of a waxy tissue resembling the medullary rays; in each zone are found a varying number of harder porous wood wedges. Each one of the different zones is mostly nearly uniform in width, so that the axis is nearly in the centre of the root. Pareira brava is nearly inodorous and has a bitter taste.

Admixtures and Substitutions.—The *stem* of chondodendron is sometimes found mixed with the commercial root, which it closely resembles. It is distinguished by being rather more woody, but more particularly by the distinct central pith.

Several drugs derived from menispermaceous plants have been sold in place of pareira brava; these consisted of roots or, more frequently, of sections of the stem. The one which was most commonly met with some years ago, consisted of woody more or less flattened pieces, with a thin brown-gray bark, often covered with patches of lichens, and upon transverse section showed numerous woody zones in more or less eccentric layers, so that the axis was removed to one side. This variety of *false pareira brava* is not readily cut with the knife, does not present a waxy appearance of the internal tissue, and, though possessed of a bitter taste, is much less so than the root of chondodendron. A second variety of false pareira, was usually in thinner pieces, of a brown color, very woody and nearly concentrically arranged in the interior, and almost tasteless.

Recently a *yellow pareira brava* has been met with in commerce, and was imported from Brazil. It consists of the flat, often twisted stems, which Bentley and Trimen presume to be obtained from Abuta amara, *Aublet.* This kind is easily recognized by the eccentric arrangement of its woody zones and by its bright-yellow color internally. C. Morrison (1878) isolated from it an alkaloid, which closely resembles berberina, but appears to be distinct from it, since with iodine it gave a reddish-brown crystalline precipitate instead of green spangles.

Hanbury mentions also a *white pareira brava*, derived from Abuta rufescens, *Aublet*, which has numerous concentric layers traversed by very distinct dark medullary rays, the interradial spaces being white and rich in starch. It is not an article of commerce.

Constituents.—Wiggers (1838) obtained an alkaloid from pareira brava, which was named *pelosina* or *cissampelina*, and was found by Flückiger to be identical with beberia (see pp. 271 and 935), and to exist also in the stem and root of Cissampelos pareira, *Lin.*, to the extent of about one-half per cent. Pareira brava contains it in the same proportion. Feneulle (1821) examined a pareira brava, and obtained a yellow bitter principle, soluble in alcohol and ether, a soft resin soluble in alcohol, and brown extractive, soluble in alcohol and water.

Off. Prep.—Decoctum pareiræ, Extract. pareiræ, *Br.;* Extract. pareiræ fluidum (liquidum), *U. S.*, *Br.;* Infusum pareiræ, *U. S.*

Medical Action and Uses.—Pareira appears to be analogous in its virtues to uva ursi, and chimaphila, since they are chiefly manifested in diseases of the mucous membrane of the urinary organs, and especially in those attended with muco-purulent deposits in the urine. In chronic *pyelitis* and *cystitis* it may be advantageously administered in the form of the officinal infusion, the decoction, or the fluid extract. The solid extract is less efficient. The *dose* is represented by thirty and from that to sixty grains of the root.

PARIETARIA.—PARIETARIA.

Pellitory, *Wall pellitory*, E.; *Pariétaire*, *Perce-muraille*, Fr.; *Glaskraut*, G.

Nat. Ord.—Urticaceæ, Urticeæ.

Description.—The following perennial European species have been used:—

Par. officinalis, *Lin.*—The stem is diffusely branched, reddish, rough-hairy; the leaves are petiolate, alternate, about an inch long, short-hairy, elliptic, entire, and acute; the polygamous flowers are in cymose axillary clusters with an involucre of short bracts, which are united at the base. The plant grows on walls and along roadsides.

Par. erecta, *Koch.*—It resembles the preceding, but is nearly simple, and has larger elliptical-ovate and pointed leaves.

Par. pennsylvanica, *Muhl.*, indigenous to the United States, probably possesses similar properties. It is an annual, has thin oblong-lanceolate, rather obtuse and opaquely-dotted leaves, and an involucre which is longer than the flowers. It grows on shaded rocky banks.

These plants are inodorous, and have a mucilaginous saline taste.

Constituents.—No complete analysis of these plants has been made. Among the saline constituents of the European species, nitrate of potassium is named.

Medical Action and Uses.—Anciently common wall pellitory was held to be astringent, cleansing, and cooling, and hence was applied in the first stage of abscesses and other local inflammations, including burns, erysipelas, inflamed hemorrhoids, gouty joints, and scaly eruptions. Its expressed juice was used as a gargle, and in modern times was taken internally, in the dose of one or two fluidounces, as a diuretic and lithontriptic.

PARTHENIUM.—FEVERFEW.

Herba matricariæ.—*Featherfew*, E.; *Matricaire*, Fr.; *Mutterkraut*, G.

The flowering herb of Pyrethrum (Matricaria, *Lin.*) parthenium, *Smith.*

Nat. Ord.—Compositæ, Senecionideæ.

Origin.—Feverfew is a perennial herb growing in waste places in Europe, and cultivated in gardens, where it is often seen with double flowers.

Description.—The stem is about two feet high, furrowed, and has alternate, petiolate, twice pinnately-cleft leaves, about three inches long and with obovate or oblong mostly toothed lobes, the teeth terminating with a white point. The flower heads are in small cymes at the end of the branches, have an involucre composed of linear scales in two rows, a naked hemispherical receptacle, white ligulate obovate and three-toothed ray florets, and tubular yellow disk florets. The herb has a peculiar odor, resembling that of chamomile, but less agreeable, and a bitter, somewhat acrid taste.

Constituents.—The bitter principle of feverfew has not been isolated; the tannin is of that variety which produces dark green precipitates with iron salts. The volatile oil contains, according to Dessaignes and Chatard (1848), a stearopten which has the composition of camphor, $C_{10}H_{16}O$, fuses at 170° C. (338° F.), and turns polarized light to the left; also another oxygenated but liquid portion, and probably a hydrocarbon.

Allied Plants.—PARTHENIUM INTEGRIFOLIUM, *Lin.*, is a North American perennial, growing in dry soil in the Southern and Western States. It is about two feet high, and has oblong or ovate leaves, of which the lower ones are sometimes lobed, and the upper ones merely crenately toothed; and small corymbose flowerheads, with a conical chaffy receptacle, five inconspicuous white pistillate ray florets and sterile disk florets. It has a bitter taste.

PARTH. HYSTEROPHORUS, *Lin.*, indigenous to the West Indies, resembles the preceding, but has bipinnatifid leaves. It is employed like feverfew.

Medical Action and Uses.—The medicinal properties of Matricaria parthenium may be referred to the bitter principle associated with the essential oil which it contains. It has been much used in the treatment of flatulent, or atonic, *dyspepsia*, in *amenorrhœa*, *dysmenorrhœa*, and simple *intermittent fever*, as well as in conditions of *nervous debility* with hysterical symptoms.

The expressed juice has been administered, and also a decoction and an infusion of the herb. The latter is sometimes applied, like chamomile, in fomentations, to allay the pain of local inflammations (toothache, abscesses, rheumatism), and to promote suppuration.

The flowering tops of Parthenium integrifolium are extremely bitter. Many years ago an infusion made from them was reported to be remarkably efficacious in curing intermittent fever. But as no further testimony has been published in confirmation of this statement, it may fairly be assumed to have been exaggerated, and that the alleged cures were only such as occasionally follow the use of various vegetable bitters.

PEPO, *U. S.*—PUMPKIN-SEED.

Semences de potirons, Fr.; *Kürbissamen*, G.

The seed of Cucurbita Pepo, *Lin.* *Nat. Ord.*—Cucurbitaceæ.

Origin.—The plant is indigenous to tropical Asia and America, and often cultivated. It has a rough hollow stem, large five-lobed, serrate leaves, five-branched tendrils, yellow bell-shaped monœcious flowers, and usually large globular or oblong fruits.

Description.—The seeds are three-quarters to one inch long, flat, broadly ovate, somewhat oblique at the pointed end, white or pale yellowish, nearly smooth or finely granular on the surface, near the edge and parallel with it marked with a shallow groove, and frequently covered with fragments of a white membranous tissue. The embryo consists of two flat cotyledons of the shape of the seed, and of a short conical radicle. It is inodorous, and has a bland oily taste.

The seeds of Cuc. melopepo, *Lin.*, the *squash*, are very similar, rather more obtuse, and less plainly margined. (See also p. 474.)

Constituents.—Dorner and Wolkowich (1870) obtained from pumpkin-seeds 44.5 per cent. of fixed oil, 32.75 starch, and traces of volatile oil, resin, and sugar. They also announced the discovery of an alkaloid, *cucurbitin;* this, however, could not be found by Kopylow (1876), who was also unable to establish the presence of a glucoside. He proved the seeds to contain free fatty acids, and the oil to consist of the glycerides of palmitic, myristic, and oleic acids. When triturated with water, the seeds yield a white and bland emulsion; the emulsionizing principle is probably a protein compound.

Medical Uses.—Pumpkin-seeds are among the most efficient remedies for *tapeworm*. Originally referred to as a vermifuge in the last century, it is only within a comparatively few years that their efficiency has been established by numerous and trustworthy witnesses, notwithstanding their neglect by most writers on helminthology. The remedy has the advantage of being free from any unpleasant taste or harsh mode of action. According to Hæckel, the tænifuge virtues reside in the perisperm. The fixed oil of the seeds, extracted by ether, has also been used successfully for the same purpose, in the dose of half an ounce repeated in two hours, and followed in two hours more by a dose of castor oil. For administration, from one to two ounces of fresh pumpkin-seeds should be deprived of their outer envelope and beaten into a paste with finely-powdered sugar, and diluted with water or milk when taken. Three or four hours later one or two tablespoonfuls of castor oil should be administered. Before taking the medicine the patient should fast for twenty-four hours. A fluid extract has also been used.

PEPSIN, *Br. Add.*—PEPSIN.

Pepsine, Fr.; *Pepsin*, G.

A preparation of the mucous lining of a fresh and healthy stomach of the pig, sheep, or calf.

Preparation.—The stomach of one of these animals recently killed having been cut open and laid on a board with the inner surface upwards, any adhering portions of food, dirt, or other impurity are to be removed, and the exposed surface slightly washed with cold water; the cleansed mucous membrane is then to be scraped with a blunt knife or other suitable instrument, and the viscid pulp thus obtained is to be immediately spread over the surface of glass or glazed earthenware and quickly dried at a temperature of not exceeding 100° F. The dried residue is to be reduced to powder and preserved in a stoppered bottle. *Br.*

This product, it will be observed, consists merely of the carefully dried mucous membrane of the stomach. A process for obtaining the digestive principle in a nearly pure state was published by Prof. E. Scheffer (1872), and is as follows: The mucous membrane of the well-cleaned fresh stomach of the hog is dissected off, chopped finely, and macerated in water acidulated with muriatic acid. After several days the liquid is strained, clarified by rest and decantation, and mixed with an equal bulk of a saturated solution of sodium chloride. The pepsin is separated floating upon the surface, drained upon muslin, and strongly pressed to remove the solution of salt. If permitted to dry, it becomes very tough, parchment-like, or leathery. Obtained in this way, it still contains mucus, phosphate of calcium, and table-salt; from the two former of which it is freed by resolution in water, filtering, again precipitating by sodium chloride, and expressing; the table-salt which now remains with it is best removed by allowing the pressed pepsin to dry, when the salt will effloresce upon the surface and will dissolve on short immersion in water. It then constitutes Scheffer's *purified pepsin*, which dissolves in acidulated water to a clear and colorless solution.

To obtain *saccharated pepsin*, the expressed residue, while still damp, is thoroughly mixed with milk sugar, and when the mixture has become air dry, its digestive power is ascertained, and the remainder is then diluted by the addition of milk-sugar, so that ten grains of it will dissolve 120 grains of coagulated albumen at a temperature of 100° F. in five or six hours.

Various other processes for obtaining pepsin have been recommended, but the saccharated pepsin, prepared as above, is most generally employed in the United States, in preference to pepsin reduced to powder by the aid of starch, which has, at least sometimes, been found to be deficient in digestive power.

Properties.—The British Pharmacopœia describes pepsin as being a light yellowish-brown powder, having a faint, but not disagreeable odor, and a slightly saline taste without any indication of putrescence. It is soluble to a very small degree in water or spirit. Two grains of it, with an ounce of distilled water to which five minims of hydrochloric acid have been added, form a mixture in which 100 grains of hard-boiled white of egg, in thin shavings, will dissolve on their being digested together for about four hours at a temperature of 98° F.

The digestive power of this pepsin, it will be observed, is about four times greater than that of *saccharated* pepsin, but much inferior to that of *purified* pepsin, one-half grain of which was observed by Scheffer to dissolve over 1500 grains of coagulated albumen in a few days. Saccharated pepsin is a pale-yellow powder, having but a slight odor and a sweetish taste, and dissolving completely in water. The solution, slightly acidulated with hydrochloric acid, furnishes precipitates on boiling, on the addition of alcohol, tannin, and sodium carbonate or bicarbonate, an excess of the last two precipitants yielding again a clear solution. Except in minute quantities, chloride of sodium impairs the digestive power of pepsin; the same is true of alcohol. When a solution of pepsin is rendered alkaline, and afterwards again acidulated, it has lost its power of dissolving fresh coagulated albumen. An aqueous solution of pepsin will decompose in a short time; after the addition of sufficient hydrochloric acid, it remains clear, but gradually loses its effects on albumen. Glycerin, on the other hand, preserves its virtues in the form of *liquid pepsin*, which is recommended by Scheffer (1870) to be made by dissolving 64 grains of saccharated pepsin in 5 fluidounces of water acidulated with 1 fluidrachm of hydrochloric acid, and adding 3 fluidounces of glycerin. Pepsin, particularly after it has been slightly acidulated, coagulates milk; 80,000 parts of the latter were found by Scheffer to be curdled by one part of purified pepsin.

GASTRIC JUICE.—As taken from the stomach and filtered from the undigested food, this forms a clear, transparent, limpid liquid of a pale-yellow or brownish color, of a slight peculiar odor, and of a somewhat saline and acidulous taste. It is but slightly heavier than water, has a strongly acid reaction to test-paper, and retains its digestive power for a long time, even after it has become mouldy. Lehmann obtained from gastric juice between 0.1 and 0.132 per cent. of free hydrochloric, and between 0.32 and 0.585 per cent. of lactic acid. The latter was observed by Richet (1878) to be identical with *sarcolactic acid* of horseflesh. The total percentage of all solids contained in gastric juice is between 1 and 1.5 per cent., but varies in different animals, and is invariably increased by admixture with saliva. The chlorides amount to nearly $\frac{1}{2}$ per cent., among them small quantities of ammonium and calcium chlorides. Phosphates of calcium, magnesium, and iron amount to $\frac{1}{5}$ or $\frac{1}{4}$ per cent.; but alkaline sulphates and phosphates cannot ordinarily be detected.

VINUM PEPSINI, s. *Vinum pepticum*, s. *Essentia pepsini*, P. G.—100 parts of the peptic mucus scraped off from the stomach of a hog or from the rennet (abomasus or fourth stomach) of an ox are mixed with 50 parts each of glycerin and distilled water, 1000 parts of good white wine, and 5 parts of hydrochloric acid, macerated for three days at or below 20° C. (68° F.), and filtered. The liquid is of a clear yellow color, and has a vinous odor and slightly acid taste.

LIQUOR SERIPARUS, *P. G.;* Rennet wine, Liquid rennet, *E.;* Laabessenz, *G.*—Three parts of the mucous membrane of calves' rennet are macerated for three days with 26 parts of sherry wine and 1 part of chloride of sodium. After filtration liquid rennet is a clear yellowish liquid.

Medical Action and Uses.—On the introduction of pepsin into medical practice it soon acquired a brilliant reputation as a remedy for numberless dyspeptic ailments indirectly engendered by the wear and tear of civilized life, as well as for those directly produced by certain affections of the structural elements of the stomach itself. The introduction into this organ from without of a substance necessary to the solution of the food, but which it was incompetent to furnish by its own power, was a happy thought of the rational therapeutist. The practical results of its application were apparently, and at first, as flattering as possible; but confidence in the remedy began to decline when it became certain that nearly all of the numerous preparations of pepsin were absolutely inert intrinsically, or had become so from the changes they had undergone by the action of time or of the various substances associated with the pepsin they originally contained. It is unnecessary to describe in detail the various *dyspeptic disorders* which might be profitably treated by a really active preparation of pepsin; it will suffice to say that besides those already referred to, there is the common gastric derangement of infants and of children during the period of dentition, induced usually by the pain and irritation of this process, which, being duly corrected, the patients are enabled to bear with comparatively slight disorder of function the continued action of the disturbing cause. Other causes besides teething may induce the same condition, including unwholesome air and food. Under the use of pepsin sometimes the vomiting and diarrhœa cease, the abdominal distension subsides, and the increased flesh and improved complexion testify to the more complete assimilation of the food. In numerous cases occurring during convalescence from exhausting acute diseases, and in the course of chronic affections, more or less of the same effect may be hoped for from the administration of pepsin in a really active condition.

Perfectly fresh pepsin may be prescribed in *doses* of about ten grains immediately before or after each meal. It should be mixed with arrowroot and given in a little sweetened water. Liebreich has found that to preserve the ferment of pepsin in the liquid state glycerin is the only reliable agent.

PERSICA.—PEACH.

Pêcher, Fr.; *Pfirsich*, G.

Persica vulgaris, *D. C.;* s. Amygdalus persica, *Lin.*

Nat. Ord.—Rosaceæ, Amygdaleæ.

Description.—The peach-tree is indigenous to Southwestern Asia, and is at present extensively cultivated in most temperate countries. It is of medium size, and has a nearly smooth brown bark and spreading branches. The *leaves* are alternate, short-petiolate, about four inches long, lanceolate, pointed, closely serrate, green, and smooth on both sides. The *flowers* appear in April, are axillary, have a bell-shaped and 5-cleft calyx; five ovate, reddish petals, about twenty-five stamens and a single ovary, developing into a subglobular drupe, with a hard and furrowed putamen, and containing a seed resembling the almond. The leaves, flowers, and seeds, when bruised, exhale a bitter-almond odor, and have a bitter taste.

Constituents.—The young branches, leaves, flowers, and seeds, after maceration in water and distillation, yield a volatile oil which is chemically identical with oil of bitter almond. Geiseler (1840) proved the presence of amygdalin in the seeds. The fixed oil of the latter is bland, and resembles expressed oil of almond (see p. 960).

Physiological Action and Medical Uses.—The bark, the leaves, the kernels, and even the flowers are endowed with active properties, which they owe, in part, to hydrocyanic acid. The flowers are chiefly laxative, and the leaves are not destitute of this quality. Indeed, they have been used as a substitute for manna, and especially for their *vermifuge* effect; they have also been reputed to cure *intermittent fevers*, and to allay the pain of *nephritic colic*, as well as to promote the discharge of calculi by causing diuresis. Bruised, and applied to the abdomen, they are said to relieve colic produced by indigestion. They are also reported to have cured *whooping-cough*. They have been applied to arrest slight *hemorrhages*. Peach-kernels have frequently produced poisonous effects. A child, three years old, who had eaten a quantity of them, became insensible, with slow, deep, sobbing respiration, slight twitching of the mouth, icy-cold extremities, lividity of the finger-nails, and dilated pupils. It was restored by an emetic (Keating). In other cases active vomiting and purging, with convulsions, have been observed. The possibility of these effects having resulted from the indigestibility of the kernels should not be overlooked. The leaves, and also the flowers, may be prescribed in an infusion, and a syrup prepared from them or from the bark has also been used.

PETROLEUM.—Petroleum.

Rock oil, Coal oil, E.; *Pétrole, Huile minéral*, Fr.; *Steinöl, Bergöl*, G.

Origin.—Petroleum is met with in several parts of North America, on the west coast of the Caspian Sea, and to a limited extent in most European countries. It oozes from the ground, frequently mixed with water, but is obtained in largest quantities from wells sunk in the ground. Its formation in the soil has been the subject of much speculation. H. Byasson (1876) explains its origin from salt water penetrating into cavities of the terrestrial crust and carrying with it limestone and other materials; if these reach a depth where the temperature is sufficiently high, and come in contact with metallic substances such as iron or its sulphurets, hydrocarbons are formed, the properties of which are modified by causes acting after their formation, such as partial distillation, etc.

Properties.—As naturally obtained petroleum varies in consistence from thin limpidity to the thickness of molasses or tar, and in color from pale-yellow to blackish-brown, usually showing a distinct fluorescence. Its specific gravity is generally between 0.8 and 0.9, but some varieties slightly exceed water in density. The heavier and dark-colored kinds yield, on rectification, light and limpid oils, and leave a residue consisting of *paraffin* and solid *bitumen*, a variety of which is found native as *asphaltum*. The latter is black, glossy, and brittle, while the bituminous residues from coal oil distillation are less glossy and scarcely brittle at the ordinary temperature. The solid as well as the liquid fractions of petroleum are inflammable and burn with a bright sooty flame; the vapors of the more volatile kinds, mixed with atmospheric air, are highly explosive.

Barbadoes tar and *Seneca oil* are two varieties of petroleum which were formerly employed; they are viscid and dark-colored, the last named lighter, thinner, and of a less disagreeable odor than the former.

Constituents.—Petroleum consists of a large number of hydrocarbons, belonging to two homologous series, namely, that of *marsh gas* of the general formula C_nH_{2n+2} (see Paraffinum), and of *olefiant gas* (olefin or ethylene series) having the formula C_nH_{2n}. On treating petroleum with strong sulphuric acid, the olefins, coloring matter, and some other constituents are removed, and the hydrocarbons of the paraffin series left. The hydrocarbons of both series exist also in isomeric modifications which differ from the normal compounds in volatility and some other properties. Those containing C_4 and less are gases at the ordinary temperatures; the relation of the others is shown by the following table (see also Paraffinum).

		Normal.	Iso.			Normal.	Iso.
Pentane,	C_5H_{12} boils at	38° C.	30° C.	Pentene,	C_5H_{10} boils at	37° C.	35° C.
Hexane,	C_6H_{14} “	70° C.	62° C.	Hexene,	C_6H_{12} “	70° C.	65° C.
Heptane,	C_7H_{16} “	98° C.	90° C.	Heptene,	C_7H_{14} “	100° C.	——
Octane,	C_8H_{18} “	124° C.	118° C.	Octene,	C_8H_{16} “	125° C.	——

These compounds are to some extent separated by fractional distillation. The portion boiling below 50° C. (122° F.) being collected by itself constitutes *naphtha*, and consists almost exclusively of pentane and pentene; but if the vapors are well refrigerated, the product contains also *butane*, C_4H_{10}, boiling at 1° C. (33.8° F.), and constitutes *rhigolene*, which requires to be kept in strong and well-corked bottles and in a cool place, since it evaporates rapidly at the common temperature. The naphtha freed from the low boiling hydrocarbons is commercially known as *benzin* or *petroleum benzin* (see page 281); its specific gravity is about .70. The portion boiling at a higher temperature is separately collected and furnishes the *coal oil* which is largely employed for illuminating purposes; its safety for that use depends upon the absence of the low-boiling hydrocarbons. At a still higher temperature paraffin oils and paraffin (see page 1035) pass over, and the residue left in the still at a temperature of about 300° C. (572° F.) constitutes the ordinary *asphaltum* or *bitumen.*

Physiological Action.—Taken internally in excessive doses, it has caused oppression, giddiness, palpitation, faintness, and headache, but no tendency to stupor or even sleep. In one case frightful tonic and clonic convulsions occurred; in another the pulse fell from 82 to 48, the pupils were contracted, the skin hot, the respiration hurried, and the voice weak. It is remarkable that it does not produce vomiting, nor, usually, diarrhœa. In only one case is death said to have resulted from it, with symptoms of gastro-enteritis, on the twentieth day after the oil was taken. The urine has a peculiar aromatic odor.

Medical Uses.—The use of petroleum by the Egyptians for embalming dead bodies is well known. Dioscorides and Pliny refer to it as being either liquid or solid. The first of these writers speaks of its application in opacity of the cornea; the Arabians refer to its emmenagogue and diuretic qualities, to its use in (humid) asthma and for cough, to its vulnerary and anthelmintic powers, and especially to its application in suppositories to remove ascarides of the rectum. They speak particularly of its use by friction to relieve rheumatic pains, assuage colic, and expel flatus, and of its efficacy in bringing on uterine contractions and expelling the dead fœtus. In more recent times it was highly esteemed in the cure of *tapeworm* and other verminous affections, and for overcoming *retention of urine* caused by atony of the bladder. It was also credited with singular virtues as an embrocation in *paralysis*, *contraction* and *stiffness* of the *joints*, atonic *rheumatism*, and atonic *tumors*, *chilblains*, etc. Still more recently the popular use of it as a remedy for *itch* has been imitated by physicians, and many cures by its means have been reported. It is said to be one of the promptest of the remedies for this affection; but it is also stated by eminent authorities not only to fail in a majority of cases, but also in some cases to be a painful application, and to produce sleeplessness, intoxication, and eczematous eruptions of the skin. It has also been found curative in *prurigo*. Dr. Frayer used petroleum in the treatment of *wounds*, and regarded it as possessing "some, if not all, of the advantages assigned to carbolic acid for this purpose."

Petroleum may be given internally in doses of from five to ten drops in the same way as oil of turpentine. For the cure of tapeworm larger doses, such as half a fluidrachm, may be used. In liniments its odor may be partially masked by that of some agreeable essential oil. It is sometimes united with cosmoline as an excipient, which renders it easy of application in all the diseases mentioned above.

Rhigolene.—Used with an ordinary hand spray-producer, furnished with metal tubes, it readily produces a temperature of 15° below zero F. It is therefore more reliable than ether for this purpose, although if its application be too long continued, it may cause frost-bite and even mortification. It was used in a great variety of cases in which local anæsthesia was required to render certain surgical operations painless, but it does not seem to have commended itself to general adoption, on account probably of its explosiveness.

PETROSELINUM, *U. S.*—PARSLEY.

Persil, Fr.; *Petersilie*, G.

The root of Petroselinum sativum, *Hofm.;* s. Apium petroselinum, *Lin.*
Nat. Ord.—Umbelliferæ, Orthospermæ.

Origin.—Parsley is indigenous to Southern Europe, and is much cultivated for culinary purposes. It is a biennial, and has bi- or tri-pinnate smooth and shining leaves, with ovate wedge-shaped three-cleft, toothed or crisp leaflets. The fruit is about one-sixteenth of an inch long, ovate, laterally flattened, brown, each mericarp with five light brown-gray filiform ribs, and six oil tubes.

Description.—The root is six or eight inches long, half to one and a half inch thick, when dry pale brown-yellow externally, annulate above, longitudinally wrinkled below, and marked with transverse corky ridges; it breaks with a short and mealy fracture, upon which is seen a thick white and in the inner layer radially striate bark, a fine dark-colored cambium line, and a yellow, soft meditullium, with irregular medullary rays. The bark and medullary rays contain scattered brown resin cells. The root is faintly aromatic, and has a sweetish taste.

Constituents.—The root contains starch, mucilage, sugar, volatile oil, and *apiin*, $C_{24}H_{28}O_{13}$. The latter is best obtained from the fresh herb by boiling with water, expressing while hot, and purifying the green gelatinous precipitate which forms on standing, by dissolving it in hot water. It was discovered by Braconnot (1843), is a white inodorous and tasteless powder, perhaps a glucoside, soluble in boiling water and alcohol, separating on cooling jelly-like; the hot aqueous solution acquires a blood-red color on the addition of ferrous sulphate.

The fruit was examined by C. Rump (1836), and found to contain 1.4 per cent. volatile oil and 22 per cent. fixed oil, besides mucilage and other common principles. *Oil of parsley* is colorless or yellowish, has the specific gravity 1.01 to 1.14, dissolves in 2½ parts of 80 per cent. alcohol, commences to boil near 170° C. (338° F.), and consists of a hydrocarbon $C_{10}H_{16}$, and a stearopten $C_{12}H_{14}O_4$. This *parsley camphor* crystallizes in silky needles or prisms, which fuse at 30° C. (86° F.), and are not sublimable; it is readily soluble in strong alcohol, ether, fixed and volatile oils, and has a faint odor of parsley, and a camphoraceous pungent taste.

Joret and Homolle (1855) separated from parsley fruit *apiol*, by exhausting with alcohol, treating the tincture with animal charcoal, distilling off three-fourths of the alcohol, dissolving in ether, evaporating the ethereal solution, macerating the residue with levigated litharge, and filtering through charcoal. A simpler process was recommended by L. Wolff (1877). The fruit is exhausted with petroleum benzin, the solvent evaporated, and the residue treated with strong alcohol, on the evaporation of which apiol is left. It is a colorless oil, of spec. grav. 1.07, becomes turbid without congealing at —12° C. (10.4° F.), has an acid reaction, the odor of parsley, and a pungent taste, forms a kind of emulsion with alkalies, and is easily soluble in alcohol, ether, chloroform, and in glacial acetic acid.

Physiological Action.—In modern as in ancient times parsley has been used as a carminative, discutient, and diuretic. The root is said to be more actively diuretic than the rest of the plant; the fruit resembles in its action those of fennel, anise, etc., and the peculiar oil, apiol, acts in part after the manner of the essential oils. Half an ounce of this oil given to a rabbit produced laborious breathing, frequent pulse, muscular debility and twitches, insensibility, coldness, and death. Given to man in doses of from seven to fifteen grains it creates a sense of warmth at the epigastrium and of general well being. Thirty and from that to sixty grains produce a state of intoxication, with scintillations before the eyes, deafness and buzzing in the ears, staggering movements, and severe headache.

Medical Uses.—Freshly bruised parsley leaves are a popular remedy for the "weed," or the engorgement of the mammæ at the commencement of lactation, and for threatening abscess of these and other external *glands*. A decoction of parsley root is useful in relieving *strangury* from cantharides and turpentine, and the painful micturition attending attacks of *gravel*. The dried leaves and the juice have been used to cure *gonorrhœa*, and also *periodical fevers* and *neuralgia;* but the seeds are said to be superior to either in the treatment of intermittent fever, when given in the form of a recently prepared and strong decoction. Its repulsive smell and taste render it a very ineligible remedy, and it is now supplanted by apiol, to which identical therapeutic powers are ascribed. The value of this agent as an antiperiodic is no better established than that of the almost innumerable medicines which are reported to cure periodical affections. The case is different in regard to *amenorrhœa*, *scanty menstruation*, and *dysmenorrhœa*, in which its efficacy is well established, whenever these affections appear to be owing to a want of activity and power in the ovarian nisus, in a word, in all those cases for which direct emmenagogues are considered appropriate. It must not be forgotten, however, that the state in question is often subordinate to or associated with a general atony of the system which requires for its cure tonics, hæmatics, and hygienic agents.

Powdered parsley seeds may be given in doses of from ten to fifteen grains. The root should be employed in the recent state and generally in strong infusion. Apiol may be administered two or three times a day in doses of five or six drops inclosed in gelatin capsules. In the uterine disorders above referred to the use of the medicine should be commenced four or five days before the expected period.

PHALARIS.—CANARY SEED.

Fructus (semen) canariense.—*Semence de canarie*, Fr.; *Kanariensamen*, G.

The fruit of Phalaris canariensis, *Lin.* *Nat. Ord.*—Graminaceæ.

Origin.—This annual grass is indigenous to the basin of the Mediterranean, and is cultivated for its fruit, which is much used as food for canaries and other birds. 131,423 bushels of canary seed were imported by the United States during the year 1876–77.

Description.—The fruit is about one-sixth of a inch long, ovate or elliptic, flattened, inclosed by glossy, yellowish-gray paleæ, after the removal of which the fruit is smooth and brownish, and internally white. It is inodorous, and has a slightly bitter taste.

Constituents.—Like other graminaceous fruits, canary seed contains starch and gluten; Dubuc ascertained also the presence in it of notable quantities of calcium chloride and of a brown bitter coloring matter.

Medical Action and Uses.—Canary seed is to be ranked with other amylaceous seeds as nutritious and emollient. It is familiar as a food for birds, and has been used by man for the same purpose, alone or mixed with wheat or rye flour. In medicine poultices have sometimes been made of it.

PHELLANDRIUM.—PHELLANDRIUM.

Fructus phellandrii, P. G.—*Five-leaved water-hemlock*, E.; *Phellandrie*, *Fenouil d'eau*, Fr.; *Wasserfenchel*, G.

The fruit of Œnanthe phellandrium, *Lam.;* s. Phellandrium aquaticum, *Lin.* *Nat. Ord.*—Umbelliferæ, Orthospermæ.

Origin.—This biennial plant grows in swampy places and on river banks in Europe and Northern Asia. It has pale-green pinnately dissected leaves, with ovate lobed or pinnately cleft leaflets, the submersed ones narrow and thread-like. The flowers are white, in compound umbels, with short linear involucral leaves. (See also page 406.)

Description.—The fruit is one-eighth to one-sixth of an inch long, nearly cylindrical, narrowed above, and oblong-ovate in shape. The three dorsal ribs are broad and obtuse, the two lateral ones larger, the four grooves narrow, each with a single oil tube and two additional oil tubes on the face of each mericarp. It is of a brown, and when collected in an unripe state of a blackish-brown color, and has an unpleasant odor, recalling that of caraway, and a bitterish, somewhat acrid taste.

Constituents.—Berthold (1818) obtained 1.5 per cent. of volatile oil, 7.8 fat and wax, 4.9 resin and other unimportant principles. Smaller quantities, .5 to .8 per cent., of volatile oil were obtained by others. Frickhinger (1839) describes the volatile oil as being brownish-yellow, limpid, of spec. grav. .86, of neutral reaction, fulminating with iodine, and possessing the odor and taste of the fruit. Distilled with potassa the alkaline distillate contained ammonia but no other alkaloid; 186 ounces of the recently dried fruit yielded over 12 drachms of ammonium sulphate. The supposed alkaloid obtained by C. Fronefield (1860) was probably identical with Devay and Guillermond's (1852) *phellandrin*, which appears to be merely volatile oil; it is volatile, liquid, neutral, and soluble in alcohol, ether, and fixed oils.

Medical Action and Uses.—Five-leaved water-hemlock has been compared in its action to conium; for it is said that some animals upon eating the fresh herb lose their muscular power, and that this effect is not produced by the dried herb. An essential oil prepared from it injected into a dog's veins in the dose of ten grains, caused dyspnœa, trembling, and anxiety for several hours. The fruit appears to be stimulant, diaphoretic, diuretic, and expectorant, and without direct and exclusive action upon the nervous system. Although recommended sometimes as a remedy for dropsy, whooping-cough, intermittent fever, etc., it is chiefly in chronic *bronchitis* that the virtues of this medicine are displayed. At a time when this affection was considered a form of consumption, phellandrium was reputed to be a remedy for the latter disease; but it is now certain that it could be useful in tubercular phthisis in so far only as it might diminish the bronchial secretion, as it does in simple bronchitis. It shares this virtue with numerous plants whose activity is due to their essential oil; but neither it nor they can be compared in efficiency with the terebinthinate and balsamic preparations. The *dose* of the powdered fruit is from thirty to sixty grains. An infusion, made with half an ounce of the bruised fruit in half a pint of hot water, may be given in doses of one or two tablespoonfuls several times a day.

PHLORIZINUM.—PHLORIZIN.

Phloridzin, Phlorrhizin.

Formula $C_{21}H_{24}O_{10}$. Molecular weight 436.

Preparation.—This principle has been obtained from the bark of the apple-, pear-, cherry-, and plum-tree, more abundantly in that of the root than in that of the stem. It is prepared from the concentrated decoction, by setting it aside and recrystallizing with the aid of animal charcoal. It was discovered by De Koninck and Stass (1835).

Properties.—It crystallizes in fine silky prisms containing $2H_2O$, becomes anhydrous at 100° C. (212° F.), fuses at about 108° C. (226.4° F.), congeals at 130° C. (266° F.), and fuses again near 160° C. (392° F.), being then converted into an isomeric modification, which is less freely soluble and crystallizable than the normal compound. Phlorizin is inodorous, bitter, neutral, colored yellow and red by sulphuric acid, and yields with ammonia, in the presence of moisture, red amorphous *phlorizein*, $C_{21}H_{30}N_2O_{13}$. Phlorizin requires about 1000 parts of cold water for solution, but is freely soluble in hot water and in two parts of cold alcohol; it is nearly insoluble in ether, and dissolves in alkalies, the solutions becoming yellow in contact with air. On being fused with potassa, *phloretic acid*, $C_9H_{10}O_3$, a crystalline homologue of salicylic and anisic acids, is obtained, together with *phloroglucin*, $C_6H_6O_3$; the solution of phloretic acid is colored green by ferric chloride.

Composition.—The empirical formula of phlorizin has been given above. According to Rochleder (1869) it belongs to the salicylic series, while *isophlorizin*, an isomeric principle of apple leaves, is classed with the benzoylic compounds. Phlorizin is a glucoside, and when continuously heated with dilute mineral acids is resolved into glucose and *phloretin*, $C_{15}H_{14}O_5$, which is nearly insoluble in water, has a sweet taste, and by hot alkalies is decomposed into phloretic acid and *phloroglucin*. The latter is a sweet crystallizing compound, which is also produced from quercetin, dragon's blood, gamboge, kino, and other compounds by heating them with hydrate of potassium; Wiesner (1878) regards it as a very delicate test for ligneous tissue, with which one drop of its dilute solution produces a beautiful red color after the addition of a drop of hydrochloric acid.

Medical Action and Uses.—In 1862 De Ricci called attention to this substance as a substitute for quinia, and a number of physicians testified to its efficacy; but soon it became apparent that the new succedaneum was neither more nor less valuable than the numerous bitter vegetable products which act as stomachic tonics and sometimes cure cases of mild *intermittent fever*. Among these medicines it is most comparable to salicin. Phlorizin is now quite disused.

PHOSPHORUS, *U. S.*, *Br.*—PHOSPHORUS.

Phosphore, Fr.; *Phosphor*, G.

Symbol P. Atomicity trivalent and quinquivalent. Atomic weight 31.

Origin and Preparation.—Phosphorus exists mostly as phosphates, in many minerals, and in all plants and animals; the bones of the higher animals are phosphate of calcium. Phosphorus was discovered by Brandt (1669), of Hamburg, among the products of the dry distillation of urine, and about 1769 Gahn and Scheele detected the presence of phosphoric acid in bones, and the latter succeeded in isolating it. Phosphorus is made by treating calcined bones with sulphuric acid, evaporating the liquid, after mixing it with powdered charcoal, to complete dryness, and distilling the residue in a stoneware retort. In case the organic matter of bones is to be utilized in the manufacture of glue, the bones are treated with muriatic acid, and the liquid treated as stated. The retort is connected with a wide bent tube which dips into water, a number of retorts are placed in each furnace, and after the distillation is completed, the melted phosphorus is strained under water, and run into tubes of suitable size, where it congeals. Phosphorus is manufactured in the United States, but much of it is still imported.

Properties.—Phosphorus is seen in commerce in the form of cylindrical sticks, which are nearly colorless or pale yellow, transparent, of a waxy lustre, and about as hard as beeswax, and flexible at ordinary, but brittle at low temperatures. It is very easily inflammable in the air, and must be preserved and cut under water, in which it is insoluble. Its density is usually about 1.77; but after purification with alcoholic potassa was found by Böttger to be 2.089. It melts at 44° C. (111.2° F.), and may be cooled to 40° C. (104° F.) before it congeals again, under certain circumstances even to 4° C. (39.2° F.), as observed by Bellani (1813). Grotthuss (1810) obtained phosphorus in an oily condition, after boiling it with alcoholic solution of potassa; and Kallhofert (1850), by slowly evaporating a solution of phosphorus in carbon bisulphide from under water. Houston and Thompson (1874) made similar observations with phosphorus treated with hot potassa solution, and regard this oil as a modification of ordinary phosphorus. The boiling point of phosphorus is 288° C. (550° F.), according to Dalton; Mitscherlich found it at 260° (500° F.); the density of the vapor is 4.3. Phosphorus is sparingly soluble in alcohol, ether, fixed and volatile oils (see Oleum phosphoratum and Pilula phosphori); it crystallizes after fusion when slowly cooled, and from its solutions in volatile oils and carbon bisulphide. Exposed to the air it emits white vapors, which have an alliaceous odor, and are luminous in the dark (phosphorescence), and when ignited burns with a brilliant white flame, giving off dense white vapors of phosphoric anhydrid. It unites directly also with sulphur, chlorine, iodine, bromine, and with many metals, and precipitates some of the latter from their solutions. When kept in water and exposed to light and air, it is superficially corroded, and becomes white and opaque (Baudrimont, 1865), while phosphorous acid is found in the water; the change does not take place in water which is free from air. Under certain conditions, phosphorus, when melted and suddenly cooled, becomes black, according to Blondlot (1869). This is due to the presence of a black body, which is rather more volatile than ordinary phosphorus. Commercial phosphorus frequently contains a little arsenic, from which it cannot be freed by distillation.

AMORPHOUS or RED PHOSPHORUS.—This was discovered by Schrötter (1848), by heating ordinary or vitreous phosphorus for a long time to near its boiling point (about 240° C. = 464° F.) in an atmosphere in which it cannot burn. It is an amorphous dark red mass or powder, becomes nearly black on being boiled with potassa solution, is insoluble in simple solvents, remains unaltered in dry air, and enters into chemical combinations less readily than the ordinary variety. According to Hittorf (1865), it has the specific gravity 2.19, is infusible, volatilizes slowly above 260° C. (500° F.), and according to Lemoine (1867), is best converted into ordinary or vitreous phosphorus by heating to near 450° C. (842° F.) in an atmosphere of nitrogen. At the temperature stated, Hittorf observed it to be converted into another modification, which forms black laminæ of a metallic lustre, is less volatile even than amorphous phosphorus, but, like the latter, is gradually converted by heat into ordinary vitreous phosphorus.

Compounds of Phosphorus. HYPOPHOSPHOROUS ACID, H_3PO_2 (molecular weight 66), is formed by boiling phosphorus with milk of lime (see p. 318), and under other circumstances. In its purest state it forms a thick uncrystallizable liquid; for medicinal purposes Procter (1858) suggested decomposing 480 grains of calcium hypophosphite dissolved in 6 ounces of water by a solution of 350 grains of crystallized oxalic acid in 3 ounces of water, filtering from the calcium oxalate, and evaporating to 8½ fluidounces, when it contains 10 per cent. of the acid.

PHOSPHOROUS ACID, H_3PO_3 (Molecular weight 82), is formed on the slow oxidation of phosphorus in moist air, and forms a crystalline deliquescent mass. If phosphorus is slowly burned with a very limited supply of dry air, *phosphorous oxide* or anhydrid, P_2O_3, is formed as a voluminous flocculent powder, which liquefies in the air by the absorption of moisture, and is gradually oxidized to phosphoric acid, or, heated in a close vessel, is decomposed into phosphoric acid and phosphoretted hydrogen.

PHOSPHORIC OXIDE, P_2O_5 (Molecular weight 142), and Phosphoric acid have been described on page 62.

Phosphorous acid and phosphites are rarely, if ever, employed in medicine. The phosphates and hypophosphites, which are sometimes used, are described under their appropriate heads. Of other chemical compounds only phosphide of zinc has been employed.

Off. Prep.—Acid. phosphoricum dilutum, *U. S.*, *Br.*; Oleum phosphoratum, Pil. phosphori, *Br.*

Medical History.—The first employment of phosphorus in medicine is ascribed by some to Kinkel in 1721, and by others to Mentz in 1751. After them it was advocated from time to time during the last and the early part of the present century, and the most extravagant statements were published of its life-giving powers; but the numerous, and generally unforeseen, dangers that sometimes followed its administration caused it to be abandoned as a medicine, and to retain its interest for physicians chiefly through its operation as a poison. Within the last few years it has once more risen into notice, in a great measure, we must believe, through the influence of those chemico-physiological doctrines which still prevail, and the predominant part which the nervous system holds in the medical theories of the day, and possibly also to the increased number of nervous diseases chargeable to the augmented wear and tear of modern life.

Physiological Action. *On Animals.*—Applied in substance or solution to the sound skin it does not usually occasion other symptoms than a superficial irritation, but, if the integument be broken, painful ulcers follow which are extremely difficult to heal, and the phenomena of constitutional poisoning are rapidly developed. It is a very striking fact, that when phosphorus in bulk is introduced beneath the skin of animals, it causes neither pain nor inflammation; and although it gives rise to toxical symptoms, the phosphorus itself retains its transparency, and does not visibly diminish in bulk. Administered internally in moderate doses, to various birds and mammals, such as ducks, rabbits, dogs, pigs, etc., it plainly acts as a stimulant of the nervous system, exciting the animals to unusual activity, and in some instances developing an exaggerated sexual excitement. Continuous administration of small doses of phosphorus to dogs produces the following effects: after two or three days the animal becomes dejected, the eyes congested, the urine is passed scantily and with straining, the pulse and the respiration are slower, and the temperature higher. Subsequently the pulse and respiration grow much quicker, and the temperature rises even to five degrees above the normal point. Death occurs without convulsions at the end of a week. On examination of the body the gastric mucous membrane is found ecchymosed, the liver soft and dark, with bloody spots on its surface, its glandular elements are in a state of fatty degeneration, the gall bladder is distended with bile containing urea and albumen; the kidneys are in a state of fatty degeneration (acute Bright's disease), which accounts for the abnormal ingredients of the bile. One-twelfth of a grain of phosphorus being given three times a day to a dog, the animal survived seventeen days. After its death a vast ecchymosis occupied the left side of the thorax, extending to the costal pleura, and even to the pulmonary in a limited space. In the right lung and in the heart were also ecchymosed spots; the pulmonary tissue was dense, dirty in color, and quite oily to the touch, and demonstrably so by microscopic examination. The liver also was slightly ecchymosed, and totally disintegrated by oily infiltration. The urine was oily and albuminous, the kidneys softened and doughy, and broken down by oily infiltration (Percy). The same lesions and symptoms essentially have been found in other animals poisoned with phosphorus. Long-continued non-poisonous doses of phosphorus occasion chronic gastritis and fatty degeneration of the stomach, liver, kidneys, heart, and other muscles, both voluntary and involuntary, and hemorrhages in various parts of the body. It, at the same time, however, appears to increase the deposit of osseous matter in the bones.

On Man.—In the dose of from one-sixtieth to one-tenth of a grain phosphorus quickens the pulse, raises the temperature, promotes perspiration and urination, increases both mental and physical activity, and sometimes excites the sexual organs. But it may, also, soon afterwards derange the digestion, causing flatulent distension, alliaceous eructations, a coated tongue, anorexia, colic, diarrhœa, vomiting, and jaundice. Sometimes these and similar symptoms appear suddenly when the treatment has been steadily continued, or when a larger and poisonous dose of two or three grains, for instance, has been taken at once. But in such cases the toxical phenomena may not appear for thirty-six hours. The first is usually a burning pain in the stomach, and vomiting of matters which are more or less luminous in the dark. The heat extends to the whole abdomen, which may be tender under pressure; the stools are loose, dark, bloody, and sometimes phosphorescent, and are voided with pain. The pulse and temperature are generally raised at first, but subsequently fall below the normal rate. Usually there is general nervous excitement, sometimes headache, giddiness, fainting, sleeplessness, delirium, spasms, convulsions, followed by collapse, coma, coldness of the extremities, strabismus, and dilatation of the pupils. In other instances death is owing to exhaustion, the mind remaining clear. Meanwhile, from the second to the fourth day, there is pain in the liver, with dark jaundice, and blood is passed by stool and in the urine, and may exhale from the gums, or appear in ecchymoses of the skin. The urine is albuminous. After death the interior of the body is everywhere phosphorescent in the dark; the stomach is seldom widely inflamed, but chiefly in the pyloric extremity, where there may also be some ulceration, and the organ is apt to contain a bloody liquid. Sanguineous effusions are also found in other organs. The blood is dark and thick, but, according to most authorities, not usually disintegrated, and it contains an undue proportion of tissue-waste in the form of uric acid, creatine, etc. The liver is of a light yellow color, and it, as well as the heart, capillary vessels, and kidneys, shows more or less distinct signs of fatty degeneration The symptoms of chronic phosphorus poisoning, as they occur, for instance, among lucifer-match makers, are briefly these: bronchial irritation and dyspepsia; a straw-colored or grayish tint of the skin; extreme sensitiveness to cold; formication; stiffness and numbness of the limbs; softening, abscess, and ulceration of the gums; loss, and sometimes decay of the teeth, with caries and necrosis of the jaw-bones. These symptoms are attended with hectic fever, and if the patient continue to work in phosphorus until they are fully developed, he is worn out by them, or dies of consumption of the lungs.

These symptoms are, in their various degrees, produced by phosphorus alone, and not by any of its alkaline compounds; its oxygen compounds occasion totally different effects, and even these are not poisonous. Phosphorus is absorbed mainly without change, and a very minute proportion of it is oxidized in the system. Its administration occasions a very small increase, if any, in the urinary phosphates; and when we remember that of these a man daily excretes not less than fifty-four grains, it is impossible to conceive that the minute quantity in which alone it is possible to administer free phosphorus can have any marked influence upon the proportion of phosphorus compounds in the tissues. Whatever action it possesses seems fairly attributable to a molecular irritation, which, if carried too far, results in tissue transformation and physiological death. This interpretation seems to be justified by the apparently successful treatment of certain paralyses by extremely minute doses of phosphorus. The confident anticipations that the physical and chemical constitution of bodies would enable us to predict their therapeutic effects, have found no support in the medical history of this substance, and, least of all, the notion that it supplies a deficiency of phosphorus in the diseased system.

Medical Uses.—Phosphorus has been employed chiefly in the treatment of diseases of the nervous system. It is useless, if not mischievous, in *epilepsy*. In *paralysis* following cerebral hemorrhage, or embolism, or their frequent consequence, softening, improvement may be attributed to phosphorus in the first case alone. But its value becomes more than doubtful when the tendency to cure after this accident is borne in mind. Possibly its stimulant influence may quicken the operations of repair, but not without the risk of increasing the mischief. The same statement is essentially true of *spinal* paralysis; but as this affection is not, like the other, always associated with a substantial lesion, the cases of paraplegia benefited by phosphorus are numerous enough to deserve a certain consideration. The same statement is applicable to *locomotor ataxia.* The persistent but moderate and interrupted use of phosphorus has unquestionably in a few instances temporarily improved the power of locomotion in this disease, but it has not, any more than other remedies, effected a cure. In regard to this class of diseases it may well be said: "Phosphorus is a rapid stimulant, but it acts by causing waste and not by increasing power, it impoverishes and does not enrich. It momentarily galvanizes, as it were, the torpid functions, but is incapable of renewing a dilapidated constitution, or even a nervous system exhausted by chronic disease" (Gubler). Although in former years phosphorus was alleged to have cured *neuralgia*, it is only of late that it has been asserted to operate "with a rapidity, a certainty, and a permanency unequalled by the action of any other medicine in this or any other disorder" (Thompson). It is said to exhibit its virtues most conspicuously, indeed to be "apparently specific," in neuralgia attended with extreme debility produced by hemorrhage, lactation, etc., when the pain follows on exposure to cold, and especially when it affects the fifth nerve. Doses less than one-twelfth of a grain of phosphorus every four hours are said to be inefficient, and it is added that if relief does not ensue in twenty-four hours, it is useless to persevere in this treatment. It is singular that, if the medicine possesses such remarkable powers, they should not have been recognized and described by other observers. But notwithstanding the extreme frequency and intractability of this disease, phosphorus is not usually employed by physicians who have had the largest experience in its treatment. In certain cases of neuralgia of the heart, or simple *angina pectoris*, the medicine is related to have entirely suspended the attacks. Phosphorus has been used with probable advantage in chronic *psoriasis*, *lepra*, *lupus*, etc., but can seldom be necessary unless after the failure of more usual remedies. It has also been credited with the cure of splenic *leucocythæmia*, but more extended and critical inquiry has proved it to be useless.

There is some reason to believe that this medicine may be serviceable in functional asthenic *amaurosis*, but in no other form of that defect of vision. In *melancholia*, and even in *dementia*, it is alleged to be useful; and still more so in that state of *nervous exhaustion* and depression which follows excessive mental or even physical fatigue. In the latter case there is a rational as well as an empirical ground for supposing that it may occasionally be useful. In regard to the reputed *aphrodisiac* action of phosphorus, authorities differ; for while one of its most moderate expositors (Lemaire) declares that if any power belongs to the drug it is certainly this, the most extravagant of its eulogists (Thompson) concludes that phosphorus is not an aphrodisiac, unless given in a larger dose than it is safe to employ for remedial purposes. In poisonous doses it certainly exerts this power upon man and animals, but only as a transient influence which is soon succeeded by genital insensibility.

In *poisoning* by phosphorus it has been usual to administer lime-water, magnesia, or charcoal, with the intention of producing a chemical combination with the two first-mentioned substances, and a mechanical mixture with the last. It should be borne in mind, however, that phosphorus does not act primarily as a corrosive poison, like several acids, and that its local gastric lesions are quite disproportioned to those which are due to its absorption. It may also be remarked that, under ordinary circumstances, the contents of the stomach do not favor the combustion of phosphorus. Oil of turpentine has been proved by numerous experiments, and by some clinical observations, to be capable of arresting the poisonous phenomena. It should be administered in doses of from fifteen to thirty drops every half hour for several hours; and meanwhile all albuminous and oily substances should be withheld. An agent, the very opposite in its chemical properties to this hydrocarbon, has recently been recommended by Percy, who claims that oxygenated water by the stomach and the inhalation of oxygen gas are the true antidotes to phosphorus, by converting it into hypophosphorous and phosphoric acids which are comparatively innocuous. This conclusion is supported by experiments on animals.

The dose of phosphorus is variously stated as between one-thirtieth and one-fourth of a grain. Those who have most advocated its use recommend that a first dose of one-eighteenth of a grain should be repeated every four hours until six doses are taken. If then no improvement have occurred, the dose should be increased to one-twelfth of a grain, and repeated in the same manner as before. Of the authorities in this matter some recommend that the medicine should be given before and some after meals. Phosphorus was originally administered in ether or alcohol, and more recently dissolved in almond oil, olive oil, cod-liver oil, glycerine, chloroform, etc., or mixed with cocoa butter, wax, soap, spermaceti, and formed into pills coated with gelatine; or, finally, in capsules containing phosphorized oil (1 : 100). Each capsule should contain one milligramme ($\frac{1}{65}$ gr.) of phosphorus. The following formula has been recommended: ℞.—Phosphori, gr. ij; Carbon. bisulphid. q. s.; solve; Saponis, Guaiaci, Resinæ, āā gr. xxxv; Glycerinæ, gtt. xij; Pulv. rad. glycyrrhiz. gr. xij.—M. ft. mass. Divide into pills of the required strength, and coat with gelatin or varnish.

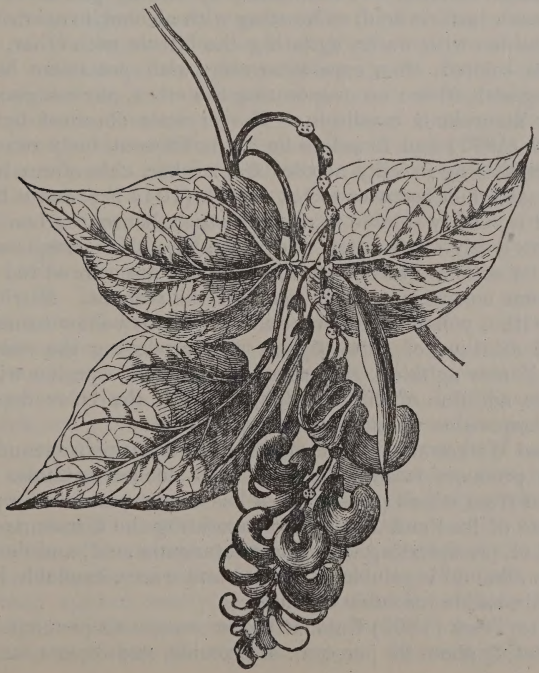
PHYSOSTIGMA, *U.S.*—CALABAR BEAN.

Physostigmatis faba, Br.; *Faba calabarica*, P. G.; *Fève de Calabar*, Fr.; *Kalabarbohne*, G.

The seed of Physostigma venenosum, *Balfour.* Transact. Roy. Soc. Edinb. xxii. tt. 16, 17; Bentley and Trimen, Med. Plants, 80.

Nat. Ord.—Leguminosæ, Papilionaceæ.

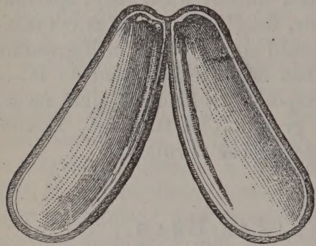
Fig. 129.



Physostigma venenosum, *Bal.* Flowering branch.

Origin.—This plant is a woody climber, growing near the mouth of the Niger and Old Calabar in Western Africa, and attaining a length of forty or fifty feet. It somewhat resembles the scarlet runner or Spanish bean of our gardens. The purple flowers are in pendulous racemes, originating from tubercular knots to the number of two or three. The curved style bears at its apex a triangular fleshy reflexed appendage. The pale-brown reticulately-veined legumes contain two or three seeds. The plant was described by Balfour in 1861, and has been introduced into India and Brazil.

Fig. 130.



Calabar bean, split, showing cotyledons.

Description.—The seeds are one to nearly one and a half inch long, about five-eighths of an inch broad, and half an inch thick, oblong and more or less reniform in shape. A well-marked black furrow, the hilum, with a ridged border, extends along the convex edge from one extremity of the seed to the other, and contains in the centre the thread-like raphe. The seed has a brittle, somewhat polished, granular testa, of a chocolate-brown color, two white cotyledons adhering to the testa, and concave upon the inner surface, thus inclosing a rather large cavity; along the hilum, each cotyledon is marked with a long shallow groove. The short radicle is situated at one end, and its position is externally indicated by the small depressed micropyle. Calabar beans are inodorous, but on the evaporation of the tincture an odor resembling that of cantharides is given off. Their taste is nearly like that of the ordinary bean.

Constituents.—The poisonous principle of Calabar beans is the alkaloid *physostigmia*, which was isolated by Jobst and Hesse (1864), and by the latter (1867) ascertained to have the composition $C_{15}H_{21}N_3O_2$. Vée (1865) proposed to call the alkaloid *eserina*. It is obtained by mixing powdered Calabar beans with one per cent. tartaric acid, exhausting with alcohol, evaporating the solvent, treating the residue with water, agitating the filtrate with ether, as long as the latter becomes colored, then supersaturating with potassium bicarbonate and again agitating with ether; on evaporating the ether, physostigmia is left behind in a colorless, amorphous condition. The crystals obtained by Vée were isolated by Hesse (1877) and found to be an indifferent body resembling cholesterin, and crystallizing in silky needles from ether, chloroform, and petroleum-benzin. Physostigmia becomes soft at 40° C. (104° F.), and is liquid at 45° C. (113° F.); it is readily soluble in alcohol, ether, benzol, carbon bisulphide and chloroform, less freely so in water, and neutralizes acids completely. The pure alkaloid and its salts are tasteless; the solutions are colored red by chlorinated lime and become colorless again by more of the reagent. Nitric acid dissolves the alkaloid with a yellow color, sulphuric acid with yellow turning olive-green. Alkalies color solutions of physostigmia red, producing the *rubreserin* of Duquesnel, and if now agitated with ether, the ethereal solution will become blue or red, on the addition of dilute sulphuric acid, the color depending on the degree of decomposition undergone by the alkaloid.

Harnack and Witkowski (1876) succeeded in isolating a second alkaloid *calabarina* which produces tetanic effects in cold-blooded animals. It is obtained from the liquid from which physostigmia has been separated, by precipitating it with subacetate of lead and ammonia, evaporating the filtrate, treating the residue with alcohol, precipitating with phosphotungstic acid, and decomposing with baryta. This alkaloid is soluble in alcohol and water, insoluble in ether, and its mercuric double-iodide insoluble in water.

According to Teich (1867) Calabar beans contain 48 per cent. of starch, 3.65 nitrogen indicating about 23 per cent. of proteids, and 3 per cent. of ash, chiefly phosphate of potassium. Mucilage and a small quantity of fat are likewise present. The alkaloids appear to exist mainly in the cotyledons; but the testa likewise possesses medicinal activity.

Adulterations of Calabar beans have not been observed by us. The seeds of a *Mucuna* and of the *Oil palm* have been mentioned, but bear no resemblance to the officinal article.

Off. Prep.—Extractum physostigmatis, *U. S.*, *Br.*

Physiological Action. *On Animals.*—After a small but fatal dose, a slight tremor seizes the animal, beginning in the posterior region and advancing forwards; paralysis follows in the same order of parts; the bowels are apt to be evacuated, and the pupils contract. Respiration becomes stertorous during inspiration and expiration, as well as slow and irregular. Slight muscular twitches appear and reflex action is annihilated; but, while the sense of pain is lost, tactile sensibility and the muscular sense are unimpaired. The rate of the heart-beat declines while the power of the systole increases until the approach of death, when it also subsides. Death does not take place by the heart, unless the dose of the poison have been very great; but is brought about by muscular paralysis of the respiratory apparatus, destroying life by an accumulation of blood in the lungs and asphyxia. Immediately after death the pupils dilate; muscular contractility is retained for some time longer, the heart may continue to act for an hour or more, and the intestines may exhibit their peristaltic movements. The large veins of the thorax are distended, as are also those upon the surface of the brain; the vascular system of the spinal cord appears natural. When a large fatal dose is given, the right and left sides of the heart and the arteries and veins, which everywhere remain well filled, present their characteristic differences of color. The peculiar tremor above referred to may be produced in dogs by the hypodermic injection of one-fifth of a grain of eseria. It may be exaggerated into distinct spasmodic movements and even general convulsions. Vomiting is usual; and salivation, also, with a frothy bronchial secretion, frequent urination, and fecal discharges, which become more and more liquid. When the poison is applied directly to a part concerned in the function of motility, it occasions paralysis of the organ. On the brain itself it exerts no action, but upon the spinal cord it first occasions a few twitches in the limbs followed by their paralysis. Applied directly to an insulated nerve-trunk it paralyzes the afferent fibres first and then the efferent. On or in the heart it arrests the action of the organ; and applied to the capillary bloodvessels, it causes their dilatation.

On Man.—In excessive but not fatal doses physostigma causes pallor of the skin, giddiness, weakness and faintness, indistinctness of vision, contraction of the pupils, nausea or vomiting, an accumulation of fluid in the mouth, a feeble but tumultuous action of the heart, and a total inability to perform voluntary muscular acts. The muscles twitch, but there is a complete absence of pain in them or elsewhere. In a few fatal cases of poisoning by this substance the following characteristic effects have been observed: Extreme muscular relaxation and debility, salivation, urgent nausea and vomiting; a slow, feeble, almost insensible pulse, coldness of the extremities, and of the skin, which is covered with a cholera-like sweat. Some colic may be felt at first, but generally no pain is experienced, although a distressing oppression of the chest is complained of. The pupils are not usually contracted. There is much vomiting and purging, the respiration is rattling, and the face livid. Consciousness remains until death, which occurs without a struggle. On dissection the body presents no characteristic lesions, unless it be a fluid condition of the blood, which also distends the heart, a flaccid state of the muscles, and some pale injection of the gastric mucous membrane. Investigations, post-mortem, taken together with the action of physostigma when applied locally, seem to render it probable that the whole chain of toxical phenomena occasioned by this substance is more readily explained by its immediate action upon the muscles or upon the nervous branches supplying them, than by its operation upon the spinal axis. This conclusion is supported by the results of its direct application to the eye. It then produces a marked contraction of the pupil, which may last in a high degree for twelve or fourteen hours, and less conspicuously for several days. But the effect is confined to the one eye, if the application is limited to one; and if it be made also to the corresponding eyelids, they become paralyzed; but no general symptoms are exhibited. It seems probable that the phenomenon of pupillary contraction by this substance is due to its dilating the bloodvessels of the iris, just as dilatation of the pupil by atropia is caused by its power of contracting the same bloodvessels.

Medical Uses.—The power of physostigma is employed to contract the pupil; for example: "In *mydriasis* dependent upon the over-action of belladonna, or as a symptom of amaurosis; in *iritis* and inflammation of the neighboring structures, where the prevention of adhesions may be more successfully secured by an alternation of contraction and dilatation, than by dilatation alone; in injuries of the eyeball with displacement of the iris, etc." Thus *prolapse*, and also *adhesion* of the *iris*, are more or less under the control of the local action of this medicine or of its use alternately with belladonna. The operation of *iridectomy* is facilitated by the tension and increase of surface which the iris, under the use of this medicine, presents. *Night blindness* has been successfully treated by instillations of a solution of eserine, which is supposed to act by augmenting the vascularity of the retina. When the sight is impaired by paralytic dilatation of the iris, this medicine is a useful palliative of the defect. Of all the medicines which have cured *tetanus*, physostigma certainly holds the first place. In 1874 an analysis of published cases showed that out of sixty-three cases of traumatic tetanus treated by this medicine, thirty-three recovered. Since then, this unusual proportion of cures of a disease which was before nearly always fatal, has been considerably increased. When the treatment has failed, as has often happened, the failure has been mainly attributable to an inefficient employment of the remedy. The minimum dose of extract of physostigma which should first be administered is one-third of a grain. It should be repeated every quarter of an hour until its specific operation is developed, and the spasms are completely overcome. This effect should be steadily maintained, and then reproduced as often as the spasms recur. It is usually necessary to increase the dose in order to maintain its original impression. In a tetanoid disease known as *tonic convulsion*, the medicine has also been successfully employed. Its efficacy in *strychnia poisoning* is not so well established, and in *chorea* it more generally fails than succeeds.

The physiological antagonism between physostigma and belladonna has been illustrated by the neutralization of the poisonous effects of the latter by the former medicine. But as fatal *poisoning by belladonna* is exceedingly rare, the practical value of the antidote is very small. That poisoning by physostigma is neutralized by the hypodermic injection of atropia has been abundantly demonstrated by experiments upon man. The antagonism is not so evident in similar experiments upon rabbits.

Physostigma has been found useful internally as a palliative of *gastralgia;* and topically its tincture is distinctly anodyne in *neuralgia* and *muscular rheumatism*, and in cases of painful malignant *tumors*.

As antidotes to the poisonous effects of physostigma, atropia should be used hypodermically, while coffee, and alcoholic and other diffusible stimulants are internally administered. If the patient is unable to swallow, artificial respiration should be maintained, mechanically as well as by means of induced electricity, and the use of atropia persisted in. The hypodermic dose of the latter should not be less than one-thirtieth of a grain.

Administration.—The commencing dose of the powdered bean is about one grain; of the officinal extract about one-tenth of a grain. There is a fluid extract of which one part represents four of the bean. A tincture is prepared by percolation, so as to produce two ounces of tincture from an ounce of the powdered bean (Fraser). The dose is about ten drops. A tincture used in Philadelphia contains in one pint the virtues of two ounces of the bean. Its dose is about twenty drops. For external use, a solution of one part of the alcoholic extract in five parts of glycerin has been employed. For application to the eye, this solution is applied on little disks of gelatine or of paper that have been soaked in it. Eserine may be applied to the eye in its original state or as a hydrochlorate, in a solution containing one part to a thousand. Internally, it may be given in the dose of from one sixty-fifth to one-twelfth of a grain.

PHYTOLACCÆ BACCA, *U. S.*—POKEBERRY.

Raisin d'Amérique, Fr.; *Amerikanische Kermesbeere*, G.

The fruit of Phytolacca decandra, *Lin.*

PHYTOLACCÆ RADIX, *U. S.*—POKEROOT.

Racine de phytolaque, Fr.; *Kermesbeerenwurzel*, G.

The root of Phytolacca decandra, *Lin.* *Nat. Ord.*—Phytolaccaceæ.

Origin.—Poke is a perennial herb, indigenous to North America, and naturalized in the West Indies and Southern Europe. It grows in waste places, and has a smooth stem four to eight feet high, alternate petiolate, ovate-oblong acute leaves, and white decandrous flowers in elongated racemes, which are usually opposite the leaves. The young shoots collected in early spring are sometimes eaten as a substitute for asparagus. It commences to flower in June, and ripens its fruits in August, when the root and berries should be collected.

Description.—1. THE ROOT. In the fresh state the root is large, conical, branched, and fleshy. In commerce, it is seen in transverse or longitudinal slices, from one to four inches in diameter, longitudinally wrinkled, yellowish brown-gray externally, hard, and breaking with a fibrous fracture. It is of a dingy white color internally, and exhibits upon transverse section a number of circles composed of wood-tissue radially divided by numerous medullary rays, and concentrically approximate, being separated from one another by shrunken parenchyma, which in the fresh state is fleshy and of about the width of the wood-circles. The root is inodorous; its taste is at first sweetish, afterwards somewhat acrid.

2. THE FRUIT is a flattened globular compound berry, about one-third inch in diameter, and composed of ten carpels which are concentrically arranged around a short axis, are laterally confluent, and contain each one lenticular black and shining seed, with the embryo curved around a mealy albumen. The fruit is of a dark purple color, has a thin pericarp, and contains a purplish-red juice which is inodorous and has a sweet and slightly acrid taste. When the berries are dried on their common peduncles, they have a slight resemblance to raisins.

Constituents.—The root was analyzed by E. Donnelly (1843), who found starch, tannin, resin, and other common constituents of plants, but did not succeed in isolating the active principle. Reichel's analysis (1836) of the root of Phytolacca (Pircunia, *Beteso*) drastica, *Pöppig*, yielded similar results; among the salts was found 6.6 per cent of calcium malate. The fruit has not been analyzed since Braconnot's experiments in 1804; its coloring matter is bleached by sunlight and turned yellow by alkalies. According to Landerer (1836) the juice is employed in Turkey for coloring sweetmeats.

Physiological Action.—Although long known to possess certain acrid and narcotic properties, poke has never been generally employed as a medicine. Its juice, or a strong decoction of the root, applied to the skin when abraded or tender, causes a smarting or burning pain; and it is reported that a person engaged in powdering the root suffered from coryza, headache, purging, and prostration. Vomiting and purging are said to have followed eating the flesh of pigeons that had fed upon the berries; but it is well known that pigeons and other birds which feed on these berries are eaten without harm. The young shoots are eaten boiled, like asparagus and cabbage sprouts. The powdered root is emetic and purgative in the dose of one or two drachms, and two teaspoonfuls of the juice of the root have produced a similar effect. It is remarkable that the evidences of gastro-intestinal irritation do not arise until an hour or two after the medicine has been taken. In an overdose, besides vomiting and purging and intense thirst, with epigastric distress, it affects the nervous system, causing great prostration, coldness of the skin, and even a cyanotic discoloration, feebleness of the pulse, drowsiness, vertigo, dimness of vision, coma, and even convulsions. In the case of a child six years old, they assumed the tetanic form. This patient recovered; but the death of an adult female from this substance is recorded. None of these effects are produced even by thirty grain doses of the powdered root.

Medical Uses.—The most probable evidence in favor of the medicinal powers of this plant relate to its use in *rheumatism*, and in *diseases of the skin.* In the former, and especially in *syphilitic* rheumatism, it has been employed as a tincture either of the root or of the berries, and as a decoction of the former; and is reputed to have displayed anodyne and sudorific powers. The decoction, the tincture, the juice of the leaves, etc., have been employed extensively and with reputed advantage, both internally and locally, in the treatment of sanious *ulcers*, *scabies*, *tinea capitis*, *sycosis*, and *favus*, and of the *mange* in dogs. An ointment made with the roots or leaves (℥ij to lb. j lard) has been used for the same purposes. All of these preparations have been much employed in the treatment of *hæmorrhoids*, and the infusion and decoction both internally and by injection. The decoction has been administered with alleged benefit in *scrofula*, as well as used locally in treating the ulcers peculiar to that disease.

In the action and in the medicinal uses of phytolacca it is difficult to avoid observing a certain analogy between it and dulcamara, on the one hand, and white hellebore, on the other. The *dose* of the powdered root as an emetic is from ten to thirty grains. Of a saturated tincture, about a fluidrachm may be given two or three times a day. An ointment may be made by mixing with an ounce of lard the extract produced by evaporating an ounce of the tincture.

PICHURIM.—Pichurim Beans.

Fèves pichurim, *Noix de sassafras*, Fr.; *Pichurimbohnen*, *Sassafrasnüsse*, G.

The cotyledons of Nectandra (Ocotea, *Mart.*) puchury major, and N. puchury minor, *Nees.*

Nat. Ord.—Lauraceæ.

Origin.—Both species are Brazilian trees with ovate smooth leaves and elliptical drupaceous one-seeded fruits, which are surrounded at the base by the hardened involucre. The embryo only is used, and is dried by artificial heat.

Description.—The so-called pichurim beans consist of the cotyledons, which are rarely united. They are oblong or roundish ovate, convex and blackish-brown on one side, nearly flat or concave and lighter colored on the other side, and near one end with a depressed scar left by the detached radicle. The large pichurim beans are from one and a half to nearly two inches long; the small rarely exceed three-fourths of an inch, and are often covered on the convex side with the pale-brown finely-wrinkled integuments. Both have internally a light-brown color with yellowish oil cells, and have an aromatic odor and taste, resembling that of nutmeg with an admixture of sassafras.

Constituents.—Kobes (1800) obtained from the large variety 2.1, and Bonastre (1821) from the small variety 3 per cent. of pale-yellow volatile oil; the latter also 10 per cent. of a butyraceous and 22 per cent. of a solid fat. Sthamer (1845) extracted the soft fat by cold alcohol, and the solid kind by boiling with alcohol and expressing; the latter is laurin. Alex. Müller (1853) separated the volatile oil by fractional distillation into a colorless pungent oil, boiling at 150° C. (302° F.); a colorless oil of an orange-like odor, boiling near 170° C. (338° F.); a yellowish-green portion, having the odor of pichurim, and boiling near 240° C. (464° F.); and a considerable quantity of a dark-blue oil, boiling at about 260° C. (500° F.), and containing a little lauric acid. All the fractions contain oxygen. Pichurim contains also starch, gum, and other common vegetable principles.

Medical Action and Uses.—Introduced a century ago into Europe by the Portuguese, pichurim beans were for a long time regarded as possessing a great medicinal value, and even very recently were included in the officinal lists of the German, Spanish, and Portuguese Pharmacopœias. They appear to depend for their virtues upon a concrete volatile oil, and have been chiefly used as stimulants and tonics in mild subacute and chronic *diarrhœa* and *dysentery*, and in habitual debility of the intestinal canal tending to produce flatulence and diarrhœa. Pichurim bark, which has an aromatic smell resembling that of nutmegs, and an astringent taste, is used in Panama in the treatment of *typhoid states* of the system, in atonic *dyspepsia*, *chronic vomiting*, *intermittent fever*, and *menstrual disorders*. The beans are given in powder in doses of from ten to twenty grains, or else in an infusion; the bark is used in the same manner, and in doses twice as great as these.

PILOCARPUS.—JABORANDI.

Pernambuco jaborandi.

The leaflets of Pilocarpus pennatifolius, *Lemaire*, s. P. pinnatus, *Mart.* (s. P. Selloanus, *Engler?*). Bentley and Trimen, Med. Plants, 48.

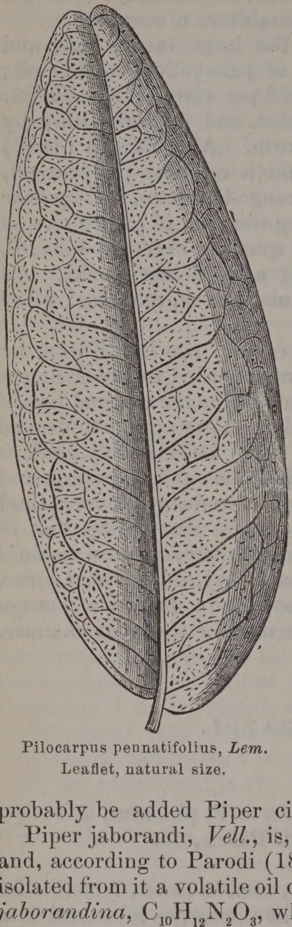
Nat. Ord.—Rutaceæ, Xanthoxyleæ.

Origin.—Jaborandi is a kind of generic name, used in South America for several plants possessing diaphoretic properties. The pilocarpus jaborandi is a shrub growing in Brazil in the neighborhood of Pernambuco, perhaps also in the southern provinces of that empire. *Pil. selloanus*, from Southern Brazil, may probably be merely a hairy variety of *Pil. pennatifolius*, but is regarded as distinct by Baillon. E. M. Holmes (1875) determined the origin of jaborandi.

Description.—The leaves are imparipinnate, and are composed of four to ten short-stalked leaflets with an unequal base, and a terminal one which has a longer stalk and is more tapering and nearly equal at base. The leaflets are about four inches long, oval or ovate-oblong, entire and slightly revolute at the margin, rather rounded below and obtuse and usually emarginate above. They are of a coriaceous texture, green and shining above, and on the under side paler and smooth or somewhat hairy and with a prominent midrib. The entire blade is marked with numerous pellucid glands. The leaves are nearly inodorous, but when bruised, exhale a slight aromatic odor; the taste is herbaceous, afterwards aromatic, warm, and somewhat bitter.

Constituents.—Byasson (1875) obtained from jaborandi leaves a volatile oil and an alkaloid, which is soluble in alcohol, ether, chloroform, ammonia, and dilute acids, and has since been called *pilocarpina.* It is obtained from the aqueous solution of the alcoholic extract by adding an alkali, agitating with

Fig. 131.



Pilocarpus pennatifolius, *Lem.* Leaflet, natural size.

chloroform, and evaporating the latter solution. The alkaloid is uncrystallizable, but A. W. Gerrard (1875) has crystallized from alcohol a number of its salts, of which the sulphate and acetate are very deliquescent; the latter is also soluble in ether, chloroform, and benzol, in which the nitrate and phosphate are insoluble, while the chlorhydrate and, bromhydrate dissolve besides in water and alcohol, also in chloroform. Kingzett (1876) gives to the alkaloid the formula $C_{23}H_{34}N_4O_4$, and states that on distillation with caustic potassa it yields trimethylamina, and that jaborandi contains only one alkaloid, while both Gerrard and Hardy (1875) believed they had evidence of the presence of a second alkaloid.

The volatile oil of jaborandi was examined by Hardy (1876), who obtained 0.56 per cent. from the leaves, and found it to consist of *pilocarpene*, which is a hydrocarbon, $O_{10}H_{16}$, sp. grav. 85, and boiling at 178° C. (352.4° F.); of another hydrocarbon boiling at 250° C. (492° F.); and a third one boiling at a higher temperature, and forming a solid transparent mass.

Other Jaborandis.—Peckolt (1875) enumerated the following Brazilian drugs, which are known in some of the provinces as jaborandi, and belong either to the natural order of Piperaceæ, or to that of Rutaceæ (Xanthoxylaceæ).

1. Serronia (Piper, *Vell.*, Ottonia, *Kth.*) jaborandi, *Guill.;* 2. Piper reticulatum, *Lin.;* 3. P. nodulosum, *Link.;* 4. Artanthe mollicoma, *Miquel;* 5. Aubletia (Monniera, *Lin.*) trifolia, *Rich.*, and Xanthoxylum elegans, *Engl.* To these must probably be added Piper citrifolium, *Lam.*, and, perhaps, other species.

Piper jaborandi, *Vell.*, is, according to Peckolt, the true jaborandi of Brazil, and, according to Parodi (1875), the true *yaguarundi* of Paraguay. The latter isolated from it a volatile oil of an acrid and biting taste, and a crystalline alkaloid, *jaborandina*, $C_{10}H_{12}N_2O_3$, which is slightly soluble in ether, and has but a weak affinity for acids.

Pharmaceutical Uses.—Jaborandi leaves are with difficulty reduced to a moderately fine powder, and, in preparing a *fluid extract of jaborandi*, Dr. F. V. Greene (1877) found it necessary to compress the moistened powder by a layer of washed sand; the drug is then exhausted with 50 per cent. alcohol, and for every 16 troyounces, 14 fluidounces of tincture are reserved, the subsequent weaker portion being evaporated to 2 fluidounces.

Physiological Action. *On Animals.*—Jaborandi and its preparations given to Guinea pigs and dogs do not occasion sweating, but in the latter animals there are profuse salivation and diarrhœa, and, when they are sacrificed, extreme congestion of the gastro-intestinal mucous membrane is found, and sometimes hemorrhage. Injected into the veins it causes primarily an increased, followed by a diminished blood-pressure and a fuller volume of the pulse-wave.

On Man.—When a leaf of this plant is chewed it causes an acrid sensation in the fauces, and the powder by prolonged contact with the skin irritates it. In doses of from thirty to ninety grains infused in boiling water, the water and the grounds being swallowed together, it produces within ten or fifteen minutes a diffused glow, followed by profuse perspiration generally, and usually by salivation so copious that it may amount to one or two pints during as many hours. It sometimes also increases the bronchial secretion, or causes diarrhœa, or produces swelling of the submaxillary glands. During the sweating the temperature is apt to fall about 1° F., the pulse grows fuller and tenser, and its rate is at the same time increased, sometimes by as much as forty or fifty beats a minute. The heart strikes forcibly against the chest, and the carotids visibly pulsate. The face becomes flushed at first, but grows pale when the perspiration is most profuse. During these operations some drowsiness is apt to occur which seems to be owing to exhaustion rather than to any narcotic virtue in the drug, and in some cases the sight is clouded, so that only very near objects can be distinctly seen. In rare instances sweating fails to occur, and salivation is much less usual than sweating. The fall of temperature noticed above seems to be ordinarily due to the diaphoresis, but it sometimes is observed independently of the latter symptom. Vomiting is an ordinary effect due in part to the irritation of the medicine when given by the stomach, but in part also to the large amount of saliva swallowed. Hiccup is not unusual. It is noteworthy that the usual promoters of diaphoresis are quite unnecessary when this medicine has been given. It is the only direct and essential diaphoretic of the materia medica. During the sweating and salivation produced by jaborandi the quantity of urine excreted is diminished, and is voided with pain. Nearly all observers agree that it contains less than the normal proportion of urea, but some have found it to be increased. Urea is, however, largely eliminated with the saliva and the sweat. Sphygmographic observations denote a dilatation and diminished tension of the whole vascular system during the action of jaborandi; and in experiments upon frogs the heart becomes gradually distended, and finally ceases to beat in diastole. The imperfect vision sometimes produced by the internal use of this drug has already been alluded to. It is attributed to a defect of accommodation. When the extract of jaborandi, or pilocarpin, dissolved in glycerin is introduced into the eye, it in most cases contracts the pupil, but when taken internally it produces this effect much less uniformly, if at all. Instead of diminishing the secretion of milk, as might reasonably be expected from its causing such profuse discharges elsewhere, it appears to be a true galactagogue. It is remarkable that children are but little affected by doses which would produce the full operation of the medicine upon adults.

Jaborandi resembles atropia in quickening the pulse and flushing the face, and in acting more powerfully upon adults than upon children; but it is antagonistic to atropia in its action upon the salivary, sudoral, and mammary secretions, upon the pupils also, and the minute arteries. Moreover, the tendency of belladonna to excite delirium contrasts with that of jaborandi to cause prostration and drowsiness, and the sweats and salivation produced by the latter are checked by the hypodermic injection of atropia. The dryness of the mouth and skin which this alkaloid or belladonna occasions is relieved by the administration of jaborandi or pilocarpin. The mammary secretion is diminished by the one and increased by the other. In this connection it may be mentioned that in experiments upon frogs the dilatation of the heart produced by the one agent has been overcome by the operation of the other. Nevertheless, it has happened in cases of poisoning by belladonna or its alkaloid, that no mitigation of the symptoms has followed the administration of jaborandi or pilocarpin.

Pilocarpin or its muriate when injected hypodermically in the dose of about one-fifth of a grain gives rise to effects which in their nature are almost identical with those of jaborandi taken internally, but they are more promptly produced, as well as more certainly, and are more lasting. Sweating, especially, which sometimes fails to occur under the operation of jaborandi, is invariably excited by pilocarpin, which is also, when thus administered, less apt to cause vomiting, probably because it does not irritate the stomach.

Medical Uses.—The utility of jaborandi in medicine is confined to its power of lessening the amount of liquid in the system. Hence it is often of service in removing effusions due to cardiac or renal obstruction, and even to inflammation. The last effect has been illustrated in some cases of chronic *pleurisy*, probably however with serous rather than purulent effusion. In *dropsy* caused by obstructive disease of the heart and kidneys it is a temporary palliative which may appropriately be used from time to time during a treatment by digitalis, etc. Indeed, it simply serves as a substitute for the ancient practice of purging by the bowels, and may be used alternately with it. Its action in lessening the contractile power of the heart and arteries, and retaining them in diastole, should be borne in mind, since it tends to favor the accumulation of blood in them, and to obstruct instead of relieving circulation and respiration. In this way, doubtless, the medicine used in certain cases of pulmonary *emphysema* has embarrassed respiration, and threatened to produce asphyxia. But when dropsy of whatever form (hydrothorax, ascites, anasarca) due to Bright's disease is associated, not with obstructive lesions of the heart, but with hypertrophy of the left ventricle, the relief obtained from jaborandi is immediate and striking. A caution has been given to beware of the possible uræmic symptoms that may follow the diminished urination; but as urea is eliminated by the saliva and sweat, the advice does not appear to be important. In scarlatinous dropsy, also, the vigor of the heart being unimpaired, great advantage may be derived from the sudation produced by this medicine, for it tends to lessen the mechanical dangers of the effusion, while other medicines may be used to remove the tubular obstruction of the kidneys. In a word, its utility in all forms of dropsy is precisely like that which has long been derived from hot air and steam-baths, and other powerful diaphoretics, but is greater, inasmuch as it causes profuse salivation as well as sweating. It must be borne in mind, also, that some clinical observers have found it injurious by causing distressing nausea and vomiting, and so exhausting the strength that its repeated use was not tolerated.

Jaborandi has been employed to diminish the discharge of urine in *diabetes insipidus*, but it only changes the outlet of the liquid without reducing the loss. Upon "scientific principles" jaborandi should be a specific for acute articular *rheumatism*, but clinically it is so far from curing that it does not modify the symptoms or the course of the disease. In syphilitic rheumatism its sudorific action is said to have removed the nocturnal pains; and it has been efficacious in muscular rheumatism and *sciatica*. In scaly *skin diseases* it is useless. In *mumps* it is reported to have been curative, both of the parotid swelling and of the metastatic engorgement of the testicles. In a case of unilateral *sweating* the hypodermic injection of pilocarpin is reported to have cured the affection after having at first increased it. In *asthma* with bronchitis (humid asthma), it sometimes affords surprising relief. A case of persistent *hiccup* from disease of the brain, and which had resisted various other remedies, yielded at once to the hypodermic injection of half a grain of pilocarpin.

Jaborandi may be administered in an infusion made with ninety grains of the medicine and four fluidounces of water, and taken in three or four equal portions at intervals of ten minutes. To avoid nausea it may be given by enema. A concentrated tincture containing the virtues of thirty grains in a fluidrachm of the preparation, and a fluid extract made with 50 per cent. alcohol, a fluidrachm of which represents sixty grains of jaborandi, have both been employed. Pilocarpin or its nitrate may be prescribed by the mouth in doses of from half a grain to three-quarters of a grain; and hypodermically a quarter of a grain may be given.

PILULÆ.—PILLS.

Pilules, Fr.; *Pillen*, G.

Pills are medicaments which have been formed into spherical, or sometimes slightly elongated or more or less lenticular bodies, intended to be swallowed without being previously masticated. Their weight ranges from less than one grain to about five grains; if a pill exceeds this weight, it is called a *bolus*. Boluses are occasionally made weighing twenty or thirty grains each, and are often of a softer consistence than pills. Very small pills, coated with sugar, have been called *granules*.

Excipients.—All drugs and chemicals may be worked into pills, but few only are adapted for this purpose without the addition of some other liquid or solid material, called the excipient, to impart to them the necessary plasticity. Soap, gum resins, some resins, and several extracts do not require any addition, except a few drops of water or alcohol, with which they may be triturated into plastic masses, and then serve as excellent excipients for many non-adhesive drugs. That the majority of extracts are unfit for the preparation of pills without the addition of an absorbent powder, is explained at page 559. Absorbent powders, like powdered marshmallow, liquorice root, bread crumb, etc., are likewise required for liquids, such as *fixed* and *volatile oils*, *oleoresins*, *balsams*, etc., but such mixtures cannot be formed into a pill mass by the addition of mucilaginous liquids. The substances named are best combined with a solid fat, like expressed oil of nutmeg, or with wax in sufficient quantity to form a plastic mass; however it is preferable in such cases to use also some absorbent powder, and for volatile oils the wax is better replaced by a resin, like mastic. The proportion in which such excipients are to be used, may be stated as being, for every five parts of the medicine, ten parts of the two excipients, of which not less than two parts should be wax, resin, or solid fat. Very limpid oils require a somewhat larger proportion of the excipients, and the absorbent powder need not necessarily be inert.

Ethers, *chloroform*, and similar liquids are not adapted for use in pill form owing to their great volatility; and tinctures, unless added only in very small quantities, in which case they are triturated with the absorbent powder, are best reduced by evaporation to the consistence of a soft extract.

It is also advisable to avoid prescribing very *deliquescent compounds* in the form of pills, unless they are immediately covered with a substance impervious to moisture; or the pill mass may be formed with a mixture of one part of wax and three parts of *Canada balsam*, as proposed by Dannecy (1877).

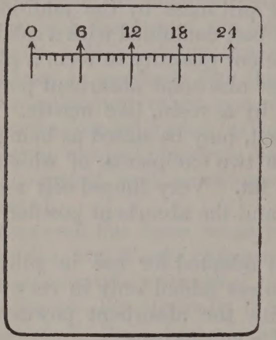
Many vegetable powders contain an amount of gum or similar principle sufficient to form, by trituration with a little water, honey, syrup, or glycerin, an adhesive mass suitable for making pills. Saline and mineral substances, as a rule, require a firmer excipient.

It is obvious, from the foregoing, that there cannot be an excipient which would be alike serviceable for all medicinal substances, or even for all drugs capable of being reduced to powder. The choice of the excipient is very frequently left to the pharmacist, and involves a knowledge not only of the constituents of the drugs, but also of the reactions which may take place between the different ingredients in the presence of moisture. *Mucilage of acacia* or of *tragacanth* serves a good purpose if the pills are to be used in a short time, but if kept on hand they become hard and dissolve very slowly. This may be prevented by replacing about one-half or more of the water with *glycerin*. The *glycerite of starch* (see p. 674), and various combinations of it with gum arabic, tragacanth, and sugar have been used for the same purpose. Some very soluble salts, like boro-tartrate of potassium, have been recommended as excipients, but are scarcely required. Most of the officinal *confections*, and more particularly that of roses, of hip and even of senna, will render powders adhesive, and if *extracts* are not inadmissible, they will be found to yield good pill masses with a comparatively large amount of powder; a rather soft extract is capable of serving as an excipient for its own weight of vegetable powder, and three or four times its weight of resins and insoluble salts, and with the addition of a little syrup, or honey, twice the weights indicated may be incorporated.

As a rule, it will be found desirable for the physician to order some adhesive material, like extracts, together with the other ingredients of pills; but the former should not be in excessive quantities, so as not to require the addition of inert absorbent powder. When no excipient is directed, the pharmacist should select one which is simple in composition, does not increase the bulk of the mass, and is not liable to become very hard. When resinous extracts and similar materials are ordered, an excipient is not often required, but the powders may be triturated together in a warm mortar, and the plastic mass rolled out into pills while still warm. The compound cathartic pills furnish an example of this kind.

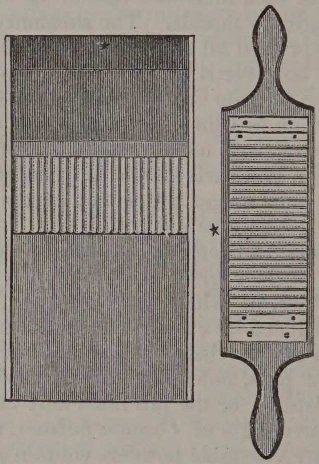
Preparation.—After the mass has been uniformly mixed and properly prepared in the mortar, or for a small number of pills upon a glazed slab, it is rolled out either by means of a spatula, or a flat piece of hard wood, or when the mass is tough or voluminous, the flat back of the cutter of a pill machine is used. A cylinder of uniform thickness and the desired length having been obtained, it is cut into the requisite number of pieces upon a graduated tile or by means of a pill machine. Several sizes of the latter are usually kept in the shops for preparing pills of different sizes, and serve not only for dividing, but likewise for shaping the pills by placing the cylindrical roll upon the cutting surface, and moving the cutter forward and backward with a gradually increased pressure. Those pieces which have not become spherical or which have been cut by hand, are rolled between the fingers until they are nearly globular, after which they are placed upon a smooth surface, and completely rounded by means of a slight pressure of the fingers, or by rotating them under the blade of a pallet knife or under a flat piece of hard wood, similar to the pill roller.

Fig. 132.



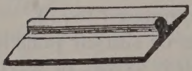
Pill tile graduated.

Fig. 133.



Pill machine.

Fig. 134.

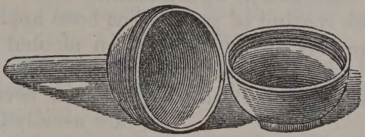


Pill roller.

Pill-dusting.—The pill mass, being plastic and adhesive, is apt to adhere to the slab and the fingers while being rolled out and shaped into pills. This is prevented by the use of a fine powder, which should be strictly inert, unless otherwise directed by the physician. Among the most suitable powders are liquorice root, marshmallow root, and lycopodium. The fineness and uniformity of the latter, its slight adhesive qualities, and its tastelessness render it particularly desirable for this purpose. Powdered starch is usually too slippery, but when mixed with finely powdered sugar and gum arabic is sometimes preferable on account of its white color. Magnesia and magnesium carbonate should be used with due care, on account of the possible effect upon the ingredients of the pills. Powdered talc (soapstone), with or without sugar and gum arabic, is likewise serviceable, and has the advantage of imparting a very thin opaque and tasteless coating to the pills without impairing their solubility in the stomach. When asafetida or other substances of a nauseous odor are given in the form of pill, the odor may either be entirely covered or considerably modified by the use of powdered cinnamon, aromatic powder, ginger, orris root, or a similar powder.

Pill-coating.—If the pill mass had not been too soft, the amount of powder adhering to the surface of the finished pill is quite small, though generally sufficient if quickly swallowed to cover the taste of bitter and nauseous ingredients. More perfect coverings may be obtained in various ways, an ordinary rather deep pill-box being used, or preferably an apparatus made of hard wood, consisting of two hollow hemispheres to one of which a short handle is attached. For *silvering* or *gilding*, the pills are made firm, if possible rolled out and shaped without using any powder, and after a perfectly smooth surface has been obtained, slightly dampened and introduced into the apparatus together with the requisite quantity of gold or silver leaf; after a rapid rotary motion for a few seconds the pills will be found uniformly coated with the thin metal. Glycerin should not be used as an excipient or only in very small quantity, as it lessens the brightness of this kind of coating.

Fig. 135.



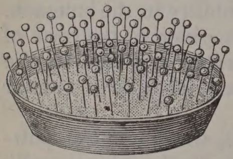
Apparatus for coating pills.

The same apparatus may likewise be employed for *sugar-coating* pills extemporaneously. To accomplish this, the pills receive first a thin coating of a thick mucilage, or preferably of syrup of acacia, by rotating them upon a moistened slab, after which they are introduced into the apparatus with not too large a quantity of finely powdered sugar. The smoothness of the surface of the sugar depends altogether upon the mutual attrition of the pills, and consequently upon the absence of too large an excess of sugar, and upon the rapidity of motion during the operation. A coating of *French chalk* may be applied in the same manner. Pills are now extensively coated with sugar on the large scale, hemispherical copper pans being used to which a somewhat eccentric rotary motion is given; these pans may be moderately heated either by steam or otherwise. To obtain a uniform and compact coating, the powdered sugar is added gradually as required.

The practice of sugar-coating pills is approved by the Pharmacopœia in reference to pills which are expected to be slow in their operation, but is stated to be of doubtful propriety in regard to those intended to act quickly, as the coating retards the solution of the pill matter in the liquids of the stomach, and the same remark holds good, with at least equal force, for nearly every other kind of coating.

Pills are occasionally coated with *tolu* or *collodion*. The operation is in both cases alike, the tolu balsam, which should for this purpose be hard at the ordinary temperature, being dissolved in ether; the pills are rapidly rotated with the ethereal liquid gradually added, a flat dish being used, and afterwards exposed upon a tile and occasionally stirred until the coating is dry.

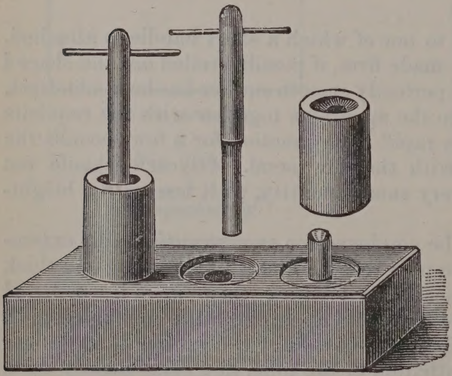
Fig. 136.



Tray with gelatin-coated pills.

For coating pills with gelatin, a different manipulation from those described is required. A solution of pure gelatin in one-half or one-third its weight of water is made, and the solution kept at a temperature just high enough to keep it liquid. The pill, fastened upon the end of a pin, is dipped into the liquid, quickly withdrawn, and after some rotary motions to promote the uniform diffusion of the gelatin solution and its superficial hardening, the pins are fixed in a tray where the coating is allowed to become sufficiently firm, when a second and sometimes a third coat is applied in the same manner. If many pills are to be thus coated, a number of pins may be fastened to a flat cork or piece of wood, and an equal number of pills dipped together. The coating of gelatin may be applied to pills while still plastic, but they should be sufficiently firm not to lose their shape while temporarily exposed to a somewhat elevated temperature. Most bitter principles being soluble in aqueous liquids, the taste of the pill mass will to some extent be communicated to the first layer of gelatin. After a sufficiently thick coating of gelatin has been applied, the pills are withdrawn after heating the pins in the flame of an alcohol or gas lamp, whereby the adjacent gelatin is melted and the orifice closed.

Fig. 137.



Apparatus for making compressed pills.

Compressed Pills.—These pills, which have been recently introduced, are usually lenticular in shape, and are made without any excipient simply by subjecting the powdered material to pressure. Prof. Remington (1876) constructed an apparatus which is made of cast-steel, the mould being on a rod which fits in a movable cylinder into which the weighed material is introduced; the compression is effected by striking the rod with a wooden mallet a quick blow. Powders which are readily soluble in water without being deliquescent appear to be best adapted for this kind of pills.

Preservation. — Uncoated pills are best preserved in lycopodium or other powder, and in a vessel which does not prevent the change of air. Moist pills kept in well-closed vessels are apt to become mouldy.

It should be mentioned that the British Pharmacopœia directs only *pill masses*, leaving the final division to be specially ordered by the physician. The U. S. Pharmacopœia, on the other hand, directs *pills* of a certain weight, and only two pill masses, namely, Pilula ferri carbonatis and Pil. saponis composita.

PILULÆ ALOES, *U. S.*—PILLS OF ALOES.

Pilula aloes Socotrinæ, Br.—*Pilules d'aloès*, Fr.; *Aloepillen*, G.

Preparation.—Take of Socotrine Aloes in fine powder, Soap in fine powder, each forty-eight grains. Beat them together with water so as to form a pilular mass, to be divided into twenty-four pills. *U. S.*

Take of Socotrine Aloes in powder two ounces; Hard Soap in powder one ounce; Volatile Oil of Nutmeg one fluidrachm; Confection of Roses one ounce. Beat all together until thoroughly mixed. *Br.*

Pilula aloes Barbadensis, Br., is made in precisely the same manner except that Barbadoes aloes is substituted for Socotrine aloes and oil of caraway for oil of nutmeg, both in the same proportion as in the preceding formula.

The Socotrine aloes in the first formula should be *purified* aloes.

Medical Action and Uses.—The soap in this pill serves to divide the aloes and render it more soluble, whereby, it is thought, the tendency of the medicine to irritate the rectum is diminished. In the British pill the presence of oil of caraway or oil of nutmeg is intended to lessen the tendency of the medicine to gripe. These pills are very convenient as laxatives in habitual *constipation*, and may be taken at bedtime or after dinner. A single pill repeated daily forms the ordinary dose. They may be used as purgatives in the *dose* of five or more pills, but are less suited for this purpose than other aloetic preparations.

The *Pilula aloes Barbadensis*, Br., is nearly identical as a purgative with that of the United States Pharmacopœia, but the oil of caraway it contains gives it the advantage. *Dose*, from five to ten grains.

The only difference between *Pilula aloes Socotrinæ*, Br., and that made with Barbadoes aloes, besides the source of the aloes itself, is that the former contains oil of nutmeg, and the latter oil of caraway. It would seem more convenient, as well as reasonable, that the one or the other oil should be added, as they may be according to the United States Pharmacopœia, according to the nature of the case. The *dose* of the Socotrine aloes pill is from five to ten grains.

PILULÆ ALOES ET ASSAFŒTIDÆ, *U. S.*, *Br.*—PILLS OF ALOES AND ASAFETIDA.

Pilules d'aloès et asefétide, Fr.; *Aloe und Asafœtida-Pillen*, G.

Preparation.—Take of Socotrine Aloes in fine powder, Asafetida, Soap in fine powder, each thirty-two grains. Beat them together with water so as to form a pilular mass, to be divided into twenty-four pills. *U. S.*

Take of Socotrine Aloes in powder, Asafetida, Hard Soap in powder, Confection of Roses, each one ounce. Beat all together until thoroughly mixed. *Br.*

Medical Action and Uses.—These pills may take the place of simple aloetic pills in cases of constipation attended with flatulence, and especially in nervous or hysterical persons. *Dose*, from two to five pills.

PILULÆ ALOES ET FERRI, *Br.*—PILLS OF ALOES AND IRON.

Pilulæ aloeticæ ferratæ s. Pilulæ Italicæ nigræ, P. G.—*Pilules d'aloès et de fer*, Fr.; *Aloe und Eisenpillen*, *Italienische Pillen*, G.

Preparation.—Take of Sulphate of Iron one ounce and a half; Barbadoes Aloes in powder two ounces; Compound Powder of Cinnamon three ounces;

Confection of Roses four ounces. Reduce the sulphate of iron to powder, rub it with the aloes and compound powder of cinnamon, and, adding the confection, make the whole into a uniform mass. *Br.*

The pills of the German Pharmacopœia are prepared from equal parts of exsiccated sulphate of iron and powdered Socotrine aloes, and with spirit formed into a mass, which is divided into pills each weighing 0.10 gram.

Medical Action and Uses.—This is an old and efficient combination used in the treatment of *amenorrhœa* associated with anæmia and constipation. Like other analogous compounds, it should be used habitually in moderate doses, and in larger ones at the menstrual epochs. *Dose*, from five to ten grains.

PILULÆ ALOES ET MASTICHES, *U. S.*—PILLS OF ALOES AND MASTIC.

Lady Webster's dinner pills, E.; *Pilules d'aloès et de mastic*, Fr.; *Aloe-und Mastix-Pillen*, G.

Preparation.—Take of Socotrine Aloes in fine powder forty-eight grains; Mastic in fine powder, Red Rose in fine powder, each twelve grains. Beat them together with water so as to form a pilular mass, to be divided into twenty-four pills. *U. S.*

Medical Action and Uses.—The association of mastic with aloes in a purgative pill can hardly have any other effect than to retard the solution of the latter, and thereby cause it to act upon the large rather than upon the small intestine. These pills are used to hasten defecation, and are generally taken with or immediately before or after the principal meal. Hence they have been called *Pil. ante cibum*, *Pilules des gourmands*, etc. Under the latter title, however, pills are used containing extract of cinchona, and absinth, as well as aloes. Each pill should contain about two grains of aloes.

PILULÆ ALOES ET MYRRHÆ, *U. S.*, *Br.*—PILLS OF ALOES AND MYRRH.

Rufus's pills, E.; *Pilules d'aloès et myrrhe*, *Pilules de Rufus*, Fr.; *Rufus'sche Pillen*, G.

Preparation.—Take of Purified Aloes in fine powder forty-eight grains; Myrrh in fine powder twenty-four grains; Aromatic powder twelve grains; Syrup a sufficient quantity. Beat the whole together so as to form a pilular mass, to be divided into twenty-four pills. *U. S.*

Take of Socotrine Aloes two ounces; Myrrh one ounce; Saffron dried one-half ounce; Confection of Roses two and one-half ounces. Triturate the aloes, myrrh, and saffron together, and sift; then add the confection of roses, and beat them together into a uniform mass. *Br.*

Medical Action and Uses.—The proportion of myrrh in this compound is too small in quantity to exert much influence; but, owing to its supposed action upon the uterine system, it is believed to increase the virtue of the aloes in the treatment of *amenorrhœa*, *uterine catarrh*, etc. The still smaller proportion of saffron can scarcely add much to its virtues. As a purgative, from three to six pills may be given, or from ten to twenty grains of the mass in a bolus. As a laxative, taken at bedtime for a week or more, one or two pills will generally suffice, and will be found the most efficient mode of administration in the uterine disorders referred to.

PILULÆ ANTIMONII COMPOSITÆ, *U. S.*—COMPOUND PILLS OF ANTIMONY.

Pilula hydrargyri subchloridi composita, Br.; *Pil. calomelanos composita.—Compound pills of subchloride of mercury, Plummer's pills*, E.; *Pilules altérantes composées, P. antidartreuses, P. de Plummer*, Fr.; *Plummer'sche Pillen*, G.

Preparation.—Take of Sulphurated Antimony, Mild Chloride of Mercury, each twelve grains; Guaiac in fine powder, Molasses, each twenty-four grains. Rub the sulphurated antimony first with the mild chloride of mercury, and then with the guaiac and molasses, so as to form a pilular mass, to be divided into twenty-four pills. *U. S.*

Take of Subchloride of Mercury, Sulphurated Antimony, of each one ounce; Guaiacum Resin in powder two ounces; Castor Oil one fluidounce, or a sufficiency. Triturate the subchloride of mercury with the antimony, then add the guaiacum resin and castor oil, and beat the whole into a uniform mass. *Br.*

Medical Action and Uses.—Plummer's pills, or compound calomel pills as they might properly be called, probably owe their virtues to the mercury they contain, since various other mercurial preparations are equally efficacious in the diseases for the cure of which these pills are in greatest repute, viz., *chronic rheumatism* and *diseases of the skin*, so far as they are due to a syphilitic taint, and since the proportion of guaiac they contain can have no efficiency. The *dose* is one or two pills twice a day.

PILULÆ ASSAFŒTIDÆ, *U. S.*—PILLS OF ASAFETIDA.

Pilule d'asefétide, Fr.; *Asafœtida-Pillen*, G.

Preparation.—Take of Asafetida seventy-two grains; Soap in fine powder twenty-four grains. Beat them together with water so as to form a pilular mass, to be divided into twenty-four pills. *U. S.*

Medical Action and Uses.—These pills, especially when sugar-coated, are a convenient form for the administration of asafetida, of which each one contains three grains. *Dose*, from one to three pills.

PILULA ASSAFŒTIDÆ COMPOSITA, *Br.* See PILULÆ GALBANI COMPOSITÆ.

PILULA CAMBOGIÆ COMPOSITA, *Br.*—COMPOUND PILL OF GAMBOGE.

Preparation.—Take of Gamboge in powder, Barbadoes Aloes in powder, Compound Powder of Cinnamon, each one ounce; Hard Soap in powder two ounces; Syrup a sufficiency. Mix the powders together, add the syrup, and beat the whole into a uniform mass.

Medical Action and Uses.—As an efficient purgative in constipation and in congested states of the portal circulation, this pill may be recommended. *Dose*, from five to ten grains.

PILULÆ CATHARTICÆ COMPOSITÆ, *U. S.*—COMPOUND CATHARTIC PILLS.

Antibilious pills, E.; *Pilules cathartiques composées*, Fr.; *Abführpillen*, G.

Preparation.—Take of Compound Extract of Colocynth thirty-two grains; Extract of Jalap in fine powder, Mild Chloride of Mercury, each twenty-four grains; Gamboge in fine powder six grains. Mix the powders together; then with water form a pilular mass, to be divided into twenty-four pills. *U. S.*

In making this pill mass it is advisable to use a warm mortar, and add very little water; while still warm, it may be formed into pills which will better retain their shape than if made with more water at the ordinary temperature.

Medical Action and Uses.—Whether or not the calomel in these pills act upon the liver as was once fully believed, there can be no question, that, in all cases requiring thorough purgation, in which the gastric digestion is disordered, the liver tumid and tender, the skin and the conjunctiva muddy, and the urine dark and sedimentary, these symptoms are promptly relieved by a full purgative dose of them. Hence, they are much used in malarial localities at seasons when periodical diseases prevail, and in other places for the relief of similar symptoms produced by the habit of eating excessively of animal food and using alcohol beyond the needs of the economy. There is much reason for believing that the compound cathartic pill operates as a purgative upon the entire intestinal tract.

The *dose* of this preparation as a laxative is about three grains, or one pill; as an active cathartic about three pills. It is not adapted for habitual use, on account of its tendency to produce salivation when often repeated.

PILULA COLOCYNTHIDIS COMPOSITA, *Br.*—COMPOUND PILL OF COLOCYNTH.

Pilules de coloquinte composées, P. cochées mineures, Fr.; *Coloquinten-Pillen,* G.

Preparation.—Take of Colocynth Pulp in powder one ounce; Barbadoes Aloes in powder, Scammony in powder, each two ounces; Sulphate of Potash in powder one-quarter ounce; Oil of Cloves two fluidrachms; Distilled Water a sufficiency. Mix the powders, add the oil of cloves, and beat into a mass with the aid of the water. *Br.*

The formula of the French Codex directs Colocynth, Barbadoes Aloes, and Scammony, of each ten grams; Honey thirty grams; Oil of Cloves 0.05 gram, to be divided into two hundred pills, which are to be coated with silver.

Medical Action and Uses.—This pill is appropriate in the same cases as the compound pill of gamboge. *Dose,* from five to ten grains.

PILULA COLOCYNTHIDIS ET HYOSCYAMI, *Br.*—PILL OF COLOCYNTH AND HYOSCYAMUS.

Preparation.—Take of Compound Pill of Colocynth two ounces; Extract of Hyoscyamus one ounce. Beat them into a uniform mass. *Br.*

Medical Action and Uses.—The operation of the compound extract of colocynth in this pill is mitigated by its association with extract of hyoscyamus; but an officinal formula is hardly necessary for such a combination. It is better to add the narcotic extract to whatever purgative pill has a tendency to gripe, in a magistral prescription. *Dose,* from five to ten grains.

PILULA CONII COMPOSITA, *Br.*—COMPOUND PILL OF HEMLOCK.

Preparation.—Take of Extract of Hemlock two and a half ounces; Ipecacuanha one-half ounce; Treacle a sufficiency. Mix the extract of hemlock and ipecacuanha, and add sufficient treacle to form a pill mass.

Medical Action and Uses.—This combination is intended to act as a sedative and expectorant, but the extract of conium contained in it can exert but little influence in either way. A pill of Dover's powder is much more efficient. *Dose*, from five to ten grains.

PILULÆ COPAIBÆ, *U. S.*—PILLS OF COPAIBA.

Pilules de copahu, Fr.; *Copaiva-Pillen*, G.

Preparation.—Take of Copaiba two troyounces; Magnesia recently prepared sixty grains. Mix them together, and set the mixture aside until it concretes into a pilular mass, to be divided into two hundred pills. Should the mixture not concrete in eight or ten hours, a deficiency of water in the copaiba may be inferred; and this difficulty may be obviated, in subsequent operations, by shaking the copaiba with one-twentieth of its weight of water, and allowing it to stand for some days, until all the uncombined water has subsided, and then decanting and keeping it in closed bottles for use. *U. S.*

The pills of the French Codex are nearly identical, each containing 0.25 gram of copaiba. The variety of copaiba best adapted for these pills is Maracaibo copaiba (p. 454), since it contains a larger proportion of resin; this enters into combination with the magnesia, forming a resin soap, which gradually becomes dry and hard. If thin Para copaiba is to be used for making these pills, it is advisable to evaporate sufficient of the volatile oil until the residue, after cooling, forms a viscid liquid, when it may be mixed with the magnesia. The Pharmacopœia directs recently prepared magnesia, which is anhydrous, and does not easily combine with the copaivic acid until after it has become hydrated. In making the mixture, it is therefore better to supply at once any deficiency in water of hydration. The combination will also be hastened by the application to the mixture of a moderate heat for about ten minutes.

In Europe pills of copaiba and powdered cubebs are sometimes used, and made into a mass by means of wax. The quantities necessary are one part of each of the ingredients named, or three parts of copaiba, five of cubebs, and one of wax. This mass retains its plasticity for a long time.

Medical Uses.—Since the introduction of capsules of copaiba these pills have become superfluous, and should be discarded from the Pharmacopœia.

PILULA FERRI CARBONATIS, *U. S.*, *Br.*—PILL OF CARBONATE OF IRON.

Pilulæ ferri carbonici, P. G.; *Pilulæ ferratæ Valleti.*—*Vallet's pill mass*, E.; *Pilules de carbonate ferreux*, *Pilules ferrugineuses*, Fr.; *Valletsche Pillen*, G.

Preparation.—Take of Sulphate of Iron eight troyounces; Carbonate of Sodium nine troyounces; Clarified Honey three troyounces; Sugar in coarse powder two troyounces; Boiling Water two pints; Syrup a sufficient quantity. Dissolve the salts separately, each in a pint of the water, and having added two fluidounces of syrup to the ferruginous solution, filter both solutions. Mix the two solutions, when cold, in a bottle just large enough to hold them, close it accurately with a stopper, and set it by that the carbonate of iron may subside. Pour off the supernatant liquid, and, having mixed water recently boiled, with syrup in the proportion of a pint to the fluidounce, wash the precipitate with the mixture until the washings no longer have a saline taste. Drain the precipitate on a flannel cloth, and express as much of the water as possible. Lastly, mix the precipitate immediately with the clarified honey and sugar, and, by means of a water-bath, evaporate the mixture, stirring constantly, until it is brought to the weight of eight troyounces. *U. S.*

Take of Saccharated Carbonate of Iron one ounce; Confection of Roses quarter of an ounce. Beat them into a uniform mass. *Br.*

The formula of the French Codex is similar to that of the United States Pharmacopœia, except that milk sugar is used in place of sugar; six parts of the mass are mixed with one part each of powdered marshmallow and liquorice root, and divided into pills, each weighing 0.25 gram, which are to be silvered. The pills of the German Pharmacopœia contain 0.05 grain of ferrous carbonate, and are rolled in powdered cinnamon.

On mixing solutions of ferrous sulphate and sodium carbonate, ferrous carbonate and sodium sulphate are formed by mutual decomposition (see p. 612). In contact with air the white iron precipitate rapidly oxidizes. The change is prevented by washing the precipitate in bottles by decantation with water recently boiled, and excluding the air; an additional protection is afforded by dissolving some sugar in the water. The pill mass, when recently made, is of a greenish-gray color, but on exposure becomes superficially greenish-black. If properly made, it contains nearly 42 per cent. of ferrous carbonate.

Medical Action and Uses.—The pill of carbonate of iron is one of the most efficient forms in which iron can be exhibited for obtaining its constitutional effects, through its digestion and assimilation. It is therefore especially indicated in pure *anæmia*, in anæmic *chlorosis*, and in all those affections in which there is a deficiency of red corpuscles in the blood, particularly when the digestive function is not greatly impaired. In the latter cases the vegetable salts of iron are preferable. The *dose* of this preparation is from three to five grains, after each meal.

PILULÆ FERRI COMPOSITÆ, *U. S.*—COMPOUND PILLS OF IRON.

Pilules de Griffith, P. de fer et de myrrhe composée, Fr.; *Griffith'sche Pillen*, G.

Preparation.—Take of Myrrh in fine powder thirty-six grains; Carbonate of Sodium, Sulphate of Iron, each eighteen grains; Syrup a sufficient quantity. Rub the myrrh, first with the carbonate of sodium, and afterwards with the sulphate of iron, until they are thoroughly mixed; then beat them with syrup so as to form a pilular mass, to be divided into twenty-four pills. *U. S.*

By the reaction between the iron and sodium salts, ferrous carbonate is formed, which, though an unstable compound when in contact with the air, is prevented to a considerable extent from becoming oxidized, except on the surface of the pills.

Pills of similar composition, but without myrrh, are used in Europe under the name of *Blaud's ferruginous pills.* Made according to the French Codex, 20 pills contain 3 grams each of exsiccated ferrous sulphate and carbonate of potassium. The ingredients may be triturated with 0.5 gram of powdered tragacanth, and, with a little honey, beaten into a good pill mass.

Medical Action and Uses.—These pills, each of which contains less than a grain of oxide of iron and a grain and a half of myrrh, are supposed to be peculiarly adapted to the treatment of *amenorrhœa* and of other conditions requiring the use of a reconstituent and stimulant medicine. They are intended to represent, in a more convenient form, the compound iron mixture; but clinical observation does not show their equality with that efficient medicine. From two to six pills may be given at a *dose*, two or three times a day.

PILULÆ FERRI IODIDI, *U. S.*, *Br.*—PILLS OF IODIDE OF IRON.

Pilules d'iodure de fer, *P. de Blancard*, Fr.; *Eisenjodür-Pillen*, G.

Preparation.—Take of Iodine three hundred grains; Iron in the form of wire and cut in pieces one hundred and twenty grains; Sugar in fine powder, Liquorice Root in fine powder, each one hundred and ninety-two grains; Liquorice in fine powder, Gum Arabic in fine powder, each forty-eight grains; Reduced Iron ninety-six grains; Water a fluidounce and a half. Mix the iodine with ten fluidrachms of the water in a glass flask, and gradually add the iron, agitate until the solution has become of a light pea-green color; filter into a porcelain capsule containing the reduced iron, and add the remainder of the water in order to wash the filter. Evaporate the solution until a pellicle forms, and add the remaining powders previously mixed together; continue the evaporation, by means of a water-bath, with constant stirring, until reduced to a pilular consistence, and divide into three hundred and eighty-four pills.

Dissolve sixty grains of Balsam of Tolu in a fluidrachm of Ether, shake the pills with the solution until they are uniformly coated, and put them on a plate to dry, occasionally stirring them until the drying is completed. Lastly, keep the pills in a well-stopped bottle. *U. S.*

Take of Fine Iron Wire forty grains; Iodine eighty grains; Refined Sugar in powder seventy grains; Liquorice Root in powder one hundred and forty grains; Distilled Water fifty minims. Agitate the iron with the iodine and the water in a strong stoppered ounce phial until the froth becomes white. Pour the fluid upon the sugar in a mortar, triturate briskly, and gradually add the liquorice. *Br.*

Each pill of the French Codex represents 0.04 of iodine and (nearly) 0.05 gram of ferrous iodide; is rolled in powdered iron, and afterwards coated with tolu. The pills of the United States Pharmacopœia represent nearly one grain of ferrous iodide; the formula of the latter authority would be much improved if the sugar was added to the solution of ferrous iodide before evaporation (see page 622). The powdered iron incorporated in the mass prevents the decomposition of the ferrous iodide.

Medical Action and Uses.—Each pill contains about a grain of iodide of iron and one-fifth of a grain of reduced iron, and may be used for the purposes to which iodide of iron in other forms is applied. These pills are reported to be useful in *anæmia* and the *scrofulous* or *tuberculous* diathesis; but the opinion is founded rather on hypothetical notions than upon a clinical basis. In point of fact glandular scrofula and pulmonary tuberculosis are neither identical nor closely allied, and while iodine and iron are both useful in the former, they are usually injurious in the latter, except when iron is demanded by the anæmic state of the system; but neither of them touches the root of the disease.

PILULÆ GALBANI COMPOSITÆ, *U. S.*—COMPOUND PILLS OF GALBANUM.

Pilula assafœtidæ composita, Br.—*Compound pill of asafetida*, E.; *Pilules de galbanum composées*, Fr.; *Galbanum-Pillen*, G.

Preparation.—Take of Galbanum, Myrrh, each thirty-six grains; Asafetida twelve grains; Syrup a sufficient quantity. Beat them together so as to form a pilular mass, to be divided into twenty-four pills. *U. S.*

Take of Asafetida, Galbanum, Myrrh, of each two ounces; Treacle by weight one ounce. Heat all together by means of a water bath, and stir the mass until it assumes a uniform consistence. *Br.*

A similar pill was formerly officinal in France as *Pilules antihystériques.*

Medical Action and Uses.—The ingredients of this compound render it more or less stimulant to the mucous membrane, and especially appropriate in chronic *pulmonary catarrh* and *uterine leucorrhœa.* It is also used in functional nervous disorders, especially of a hysterical nature. *Dose* from five to twenty grains, or from two to four pills.

PILULÆ HYDRARGYRI, *U. S.*—PILLS OF MERCURY.

Pilula hydrargyri, Br.; *Pilulæ cæruleæ; Massa cærulea.—Blue pills, blue mass,* E.; *Pilule de mercure, P. bleues,* Fr.; *Mercurial-Pillen,* G.

Preparation.—Take of Mercury three hundred and eighty-four grains; Confection of Rose five hundred and seventy-six grains; Liquorice Root in fine powder one hundred and ninety-two grains. Rub the mercury with the confection until the globules cease to be visible; then add the liquorice root, and beat the whole into a pilular mass, to be divided into three hundred and eighty-four pills. *U. S.*

Take of Mercury two ounces; Confection of Roses three ounces; Liquorice Root in fine powder one ounce. Rub the mercury with the confection of roses until metallic globules are no longer visible; then add the liquorice, and mix the whole well together. *Br.*

The pills of the French Codex represent 0.05 gram (¾ grain) of mercury each.

The Pharmacopœias recognize blue mass of such a strength that it represents one-third of its weight of mercury. The extinction of the mercury is very much facilitated, if, instead of following the manipulation of the Pharmacopœia, the finely powdered liquorice root is triturated with the mercury and 72 grains of honey; 96 grains of rose-water are gradually added, and the trituration is continued until globules of mercury are no longer visible even on pressing a small portion of the mass upon paper; 360 grains of sugar and 48 grains of finely powdered rose leaves are added, and the whole rubbed together until a uniform mass is obtained. Should the mixture become too dry, a little distilled water may be added, and, after the incorporation has been completed, allowed to evaporate again spontaneously. Proceeding in the manner indicated, no difficulty will be experienced in preparing, in a short time, a supply sufficient to last for several months, and strictly identical with the requirements of the Pharmacopœia.

Blue mass or blue pill is not unfrequently ordered in powders, but is unsuited for the purpose unless mixed with other absorbent powders. It may, however, be readily obtained in the state of a permanent powder having the same relative composition as the pill mass, by substituting in the above directions, for the honey and rose water, an equal weight of milk sugar, using a drop of oil of roses to impart the requisite flavor, and keeping the mixture moist by the addition of alcohol; after a uniform mass has been obtained, it is spread out to allow the alcohol to evaporate spontaneously, after which it may be reduced to a permanent powder.

When properly prepared, blue mass contains metallic mercury in the state of very fine division. It is not impossible that when kept on hand for a long time, a change, due to the partial oxidation of mercury, may gradually take place. Such a change, however, could only be very superficial, since the metal is well protected by the other ingredients of the pill mass.

Medical Action and Uses.—Pills of mercury, or blue pills, differ from all other preparations of the metal in being less irritating to the stomach and bowels, and therefore less apt than they to act as cathartics; but, for this reason probably, they are also more likely to form combinations in the primæ viæ, which are readily absorbed, and produce the constitutional effects of the medicine. These effects are, therefore, very commonly sought to be induced by the medicine in question, given in doses of three grains or less, repeated two or three times a day until the characteristic soreness of the gums is observed. If it tends to operate as a laxative it is usually associated with a quarter of a grain of opium, or less, in each pill, or the mercurial is repeated at intervals of an hour or two in doses of a third or a quarter of a grain. When it is desired to excite by means of this mercurial the gastro-intestinal secretions, and those of the *liver* and *pancreas*, a dose of from three to six grains is administered at night, and is followed the next morning by a saline or senna draught, or other analogous cathartic. Whether the mercury does or does not specifically promote the secretions of the glands referred to is a question still undetermined, and which is discussed elsewhere (see Hydrargyrum).

PILULA IPECACUANHÆ CUM SCILLA, *Br.*—PILL OF IPECACUANHA AND SQUILL.

Preparation.—Take of Compound Powder of Ipecacuanha three ounces; Squill in powder, Ammoniacum in powder, each one ounce; Treacle a sufficiency. Mix the powders, and beat into a mass with the treacle. *Br.*

Medical Action and Uses.—The presumed effect of this pill is to mitigate *bronchitis* in its chronic and especially its senile forms, by a combined sedative and stimulant action. There can be no question of its utility in many cases for which the balsams and terebinthinates are too stimulating. *Dose*, from five to ten grains.

PILULÆ OPII, *U. S.*—PILLS OF OPIUM.

Pilules d'opium, Fr.; *Opiumpillen*, G.

Preparation.—Take of opium in fine powder twenty-four grains; Soap in fine powder six grains. Beat them together with water so as to form a pilular mass, to be divided into twenty-four pills. *U. S.*
